# Using Low-cost Cryptographic Hardware to "Rob a Bank"

(or, "Why I was wearing a tie on the telly")

#### **Richard Clayton**

Presented at: Compsoc, Oxford, 31st October 2002

# Cambridge University Computer Laboratory Security Group

### Summary

- Keys and Ciphers
- Tampering and the IBM 4758 Cryptoprocessor
- How PIN values work
- Mike Bond's "API attacks"
- The low-cost hardware "DES cracker"
- How to extract 3DES keys from a IBM 4758
- Some thoughts on "full disclosure"

## Keys and Ciphers

- Kerckhoff's doctrine (1883)
  - the security of a system should depend upon its key and not upon its design remaining obscure
- If there is no shortcut then the security of a system depends upon its key length
  - trying all possibilities @ 33 million keys/sec
    - $2^{40} = 9.25$  hours
    - $2^{56} = 69.2$  years
    - $2^{80} = 1.2$  billion years

## A History of Tamper Resistance

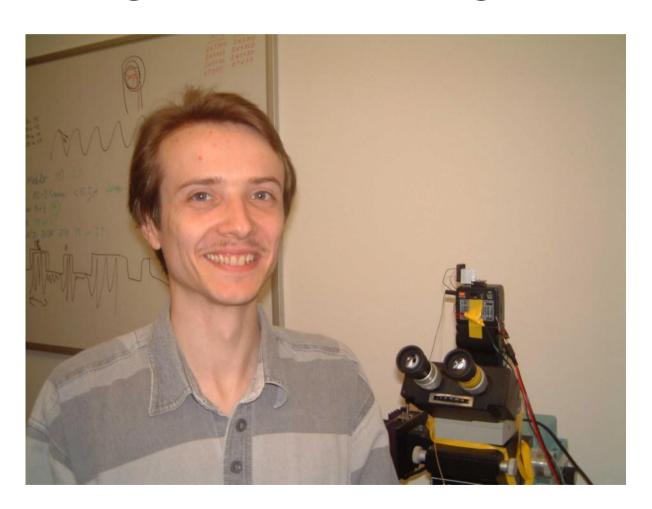

**Problem**: another program on the same machine can access your sensitive data

- Put keys into separate microprocessor
- Put microprocessor into a tin box
- Photocells and tilt detection
- Epoxy "potting"
- Tamper detecting barriers

#### Smartcards: NOT Well Protected

- Simple attacks on Vpp, slow clocks &c
- Damage the processor to access all RAM
- Probing
- Focused Ion Beam (FIB) workstations
- Power analysis
- Attacks with flashguns!

# Sergei P. Skorobogatov

#### The IBM 4758

- Protective barrier with wires of chemically similar compound
- Detectors for temperature & X-Rays
- "Tempest" shielding for RF emission
- Low pass filters on power supply rails
- Multi-stage "ratchet" boot sequence
  - = STATE OF THE ART PROTECTION!

#### CCA and PIN values

- Common Cryptographic Architecture
  - runs on many IBM platforms
  - available for free to run on a 4758
- A PIN value (in the CCA world) is the account number encrypted with (112 bit) 3DES key and last few bytes made decimal
- Changing a PIN => changing an offset

### Key Entry under CCA

- Each key is loaded in two parts, which are then XORed together
  - XOR means that knowing one part tells you
     NOTHING about the final key value
- Two security officers, "trusted" not to collude, are given one part of the key each.
  - they authenticate themselves and then separately load these into the 4758.
- This makes the key entirely secure...

## Mike Bond

#### Michael Bond's "API attacks"

- New type of attack: use standard API in non-standard way to cause dumb things
  - Overloaded key types
  - Unauthorised type casting
  - 3DES binding attack
  - Related keys

Mike's PhD topic targets formal methods that will detect (and avoid) these problems

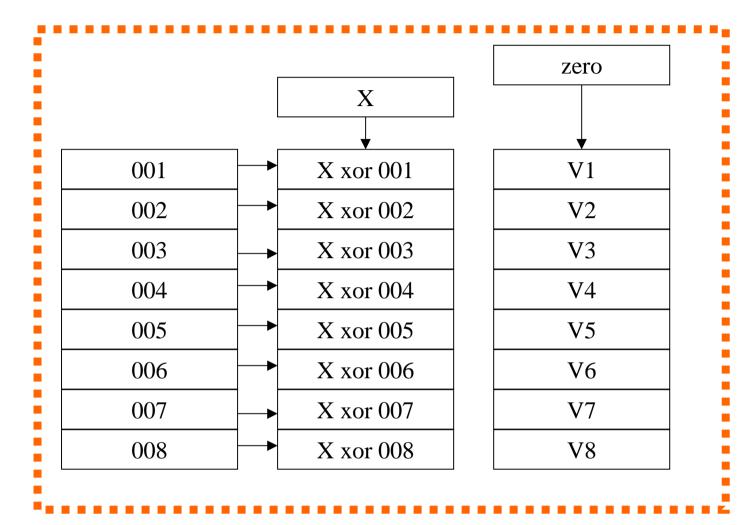

#### The Meet-in-the-Middle Attack

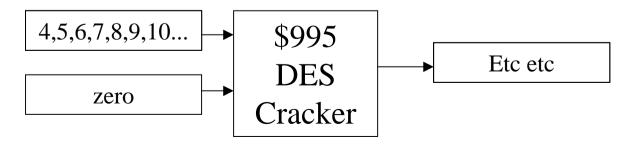

Idea: Attack multiple keys in parallel

- Encrypt the same plaintext under each of the multiple keys to get a "test vector"
- Attack by trying all keys in sequence but check for a match against any test vector value (check is faster than encrypt)
- Typical case: A 2<sup>56</sup> search for one key becomes a 2<sup>42</sup> search for 2<sup>14</sup> keys

## Attacking the CCA: Part 1

- Create unknown DES key part
- XOR in "...001", "...002", "...003" etc
- Encrypt zero value under each key
- Repeat to get 16384 (2<sup>14</sup>) results
- Some complexity because of parity issues, but essentially simple & takes 10 minutes.
- Use "brute-force" attack to get the DES key

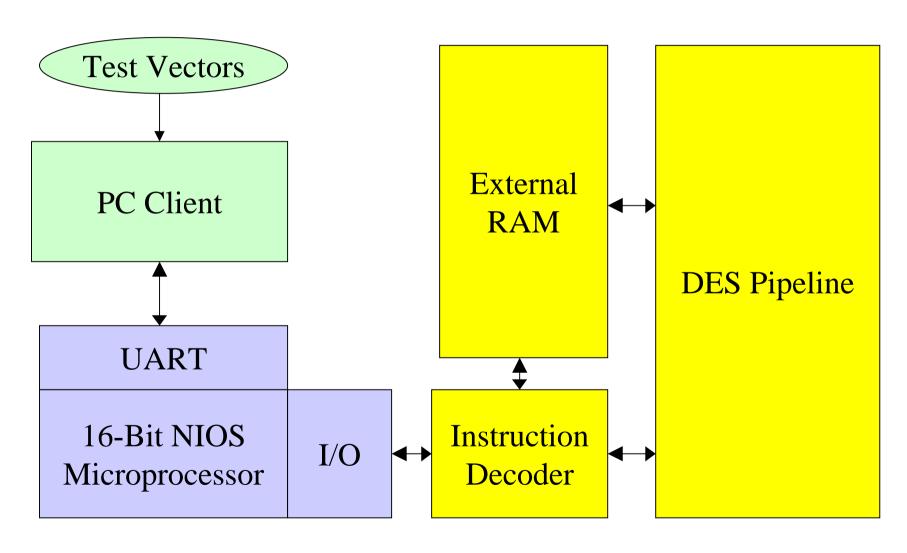

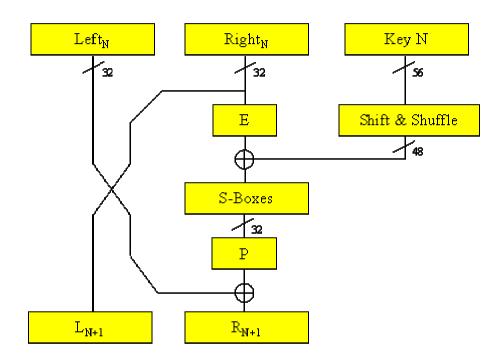

#### Low-cost DES Cracker

- \$995 Excalibur kit (Altera 20K200 FPGA)
  - chip cost is ~\$5 (in volume; \$178 one-off)
- 33MHz pipeline (& 60MHz possible)
- 2<sup>25</sup> keys/second
  - -56 bit DES = 68 years
- However.. it looks for 16384 keys in parallel
  - with average luck find first key in 25.4 hours

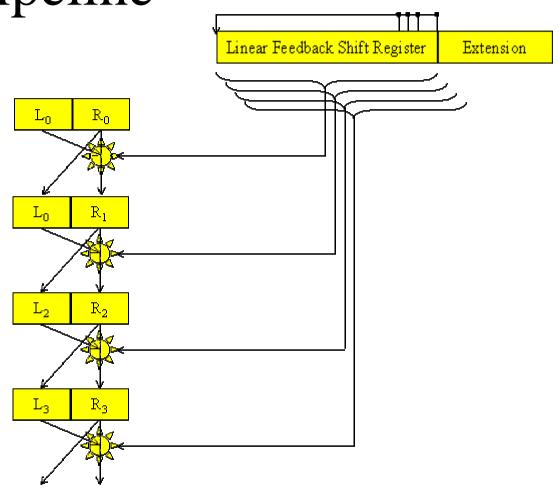

## Design Overview

# A DES Pipeline Stage

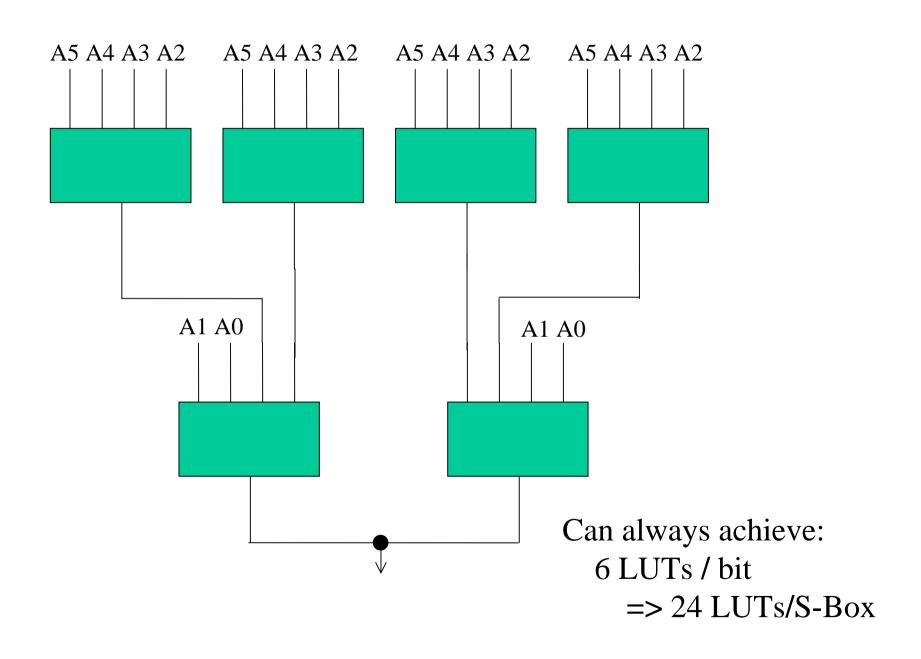

# DES Pipeline

## Fitting the Design Onto the Chip

Max of 8320 LUTs ... and using all except 17

- LFSR saves pipelining key values
- Careful attention to instruction decoder
- Minimal settings for NIOS processor
- Redesigned S-Boxes

#### Some S-Boxes Have Structure

• SBOX4 : address : 543210 : 4 bit result =

```
7, 13, 14, 3, 0, 6, 9, 10, 1, 2, 8, 5, 11, 12, 4, 15, 13, 8, 11, 5, 6, 15, 0, 3, 4, 7, 2, 12, 1, 10, 14, 9, 10, 6, 9, 0, 12, 11, 7, 13, 15, 1, 3, 14, 5, 2, 8, 4, 3, 15, 0, 6, 10, 1, 13, 8, 9, 4, 5, 11, 12, 7, 2, 14.
```

• Rearrange addressing in order 532104

```
7, 14, 0, 9, 1, 8, 11, 4, 10, 9, 12, 7, 15, 3, 5, 8, 13, 11, 6, 0, 4, 2, 1, 14, 3, 0, 10, 13, 9, 5, 12, 2, 13, 3, 6, 10, 2, 5, 12, 15, 6, 0, 11, 13, 1, 14, 2, 4, 8, 5, 15, 3, 7, 12, 10, 9, 15, 6, 1, 8, 4, 11, 7, 14.
```

and then feed it into the logic minimiser...

$$X2 = a[4] & (a[5] & !a[3] # !a[5] & a[3] & !a[2])$$
  
# !a[4] & (a[3] \$ (!a[2] # !a[5]));

$$X3 = a[4] & a[2] & (a[3] # !a[5])$$
  
# !a[4] & (a[2] \$ (a[5] # a[3]));

$$X4 = a[4] & (a[5] & !a[3] & !a[2] # !a[5] & a[2])$$
  
# !a[4] & (a[5] \$ !a[3]);

$$R0 = a[0] \# a[1] \& X4 \# !a[1] \& !X3;$$
  
 $R1 = a[0] \# a[1] \& !X1 \# !a[1] \& X2;$ 

ie: SBOX4 uses just 16 LUTs, not 24

savings also on:

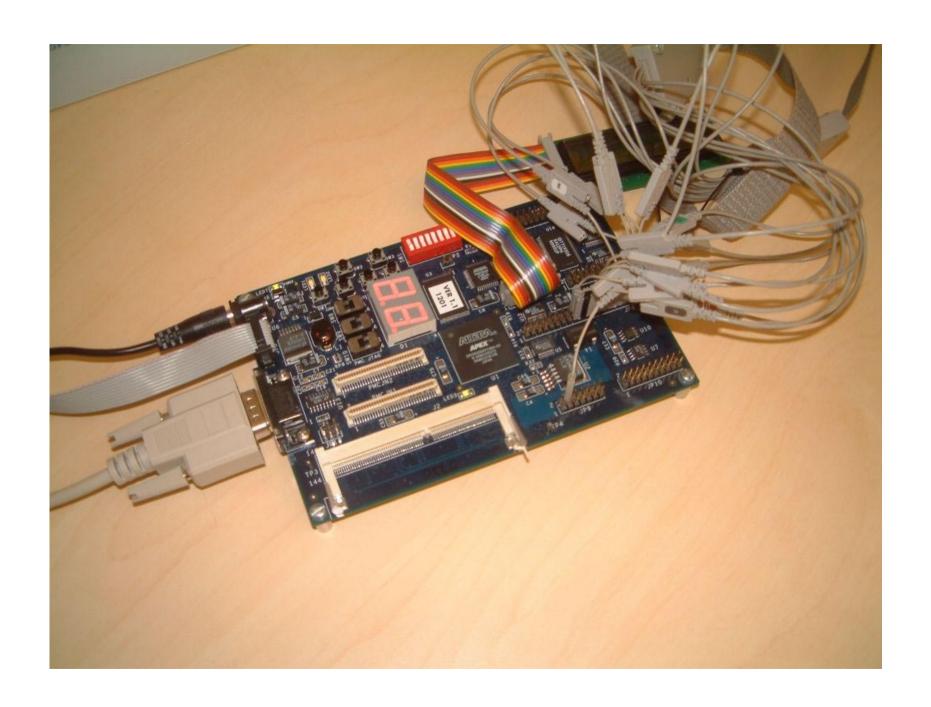

SBOX2: 23

SBOX3: 23

SBOX7: 23

SBOX8: 22

total = 13 LUTs(\* 16 stages = 208)

## Why Use Hardware Anyway?

Hardware DES implementation is >>25 times faster than the best software implementations.

- eg: Software [seeking any 1 of 64K keys]
  - 6 modern PCs running in parallel
  - £4500
  - 84 hours (3.5 days)
- & Hardware [seeking any 1 of 16K keys]
  - Altera evaluation board (no soldering required)
  - \$995
  - 22.5 hours (for same example, NB: 1/4 parallelism)

## Attacking the CCA: Part 2

- Recall we had 16K related DES keys
- We can crack one of these in ~1 day
- Now create 16K related 3DES keys with "replicate" halves and "exporter" capability
  - 3DES = EncryptA; DecryptB; EncryptA
- Export the DES key under the 3DES keys
- Since replicate can also crack in ~1 day

## Attacking the CCA: Part 3

- Create non-replicate 3DES key by combining two unequal halves with the replicate halves that we've now determined
- Export all the CCA keys under this key
- Download list of PIN offsets
- Use magnetic stripe writer to create cards
- Use any ATM to extract money from accounts
- Go to Bermuda!

## IBM's Response

- Nov 2000 (Mike's first results)
  - nothing (typecasting seen as legitimate)
- May 2001 (Mike's CHES paper)
  - nothing
- Nov 2001 (Newsnight program)
  - attack "infeasible in realistic system implementations"
  - followed by advice to disable Combine\_Key\_Parts
- Feb 2002
  - new version of CCA available [+ bug fix]

#### "Full Disclosure"

- Should you tell vendor & keep quiet?
  - vendor has limited incentive to act
- Should you publish & be damned?
  - "black hats" may be unaware of problem
- Should exploits be published?
  - "script kiddies" & sysadmins both need them
- Current consensus is to tell vendor and publish after pre-set delay. Recent decisions to suppress exploit info are controversial.

#### Make Your Own!
