Lecture 09 and 10

Two Themes ...

- Redundancy can be a GOOD thing!
- Duplicates, aggregates, and group by in SQL, and evolution to "Data Cube"

.... come together in OLAP

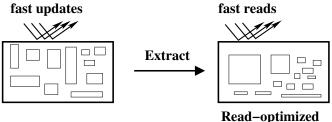

- OLTP : Online Transaction Processing (traditional databases)
 - Data is normalized for the sake of updates.
- OLAP : Online Analytic Processing
 - These are (almost) read-only databases.
 - Data is de-normalized for the sake of queries!
 - Multi-dimensional data cube emerging as common data model.
 - This can be seen as a generalization of SQL's group by

A > + = + + =

Materialized Views

- Suppose Q is a very expensive, and very frequent query.
- Why not de-normalize some data to speed up the evaluation of Q?
 - This might be a reasonable thing to do, or ...
 - ... it might be the first step to destroying the integrity of your data design.
- Why not store the value of Q in a table?
 - This is called a materialized view.
 - But now there is a problem: How often should this view be refreshed?

Normalized Database

(NOT Normalized)

OLAP vs. OLTP

OLTP Online Transaction Processing

OLAP Online Analytical Processing

 Commonly associated with terms like Decision Support, Data Warehousing, etc.

	OLAP	OLTP
Supports	analysis	day-to-day operations
Data is	historical	current
Transactions mostly	reads	updates
optimized for	query processing	updates
Normal Forms	not important	important

OLAP Databases : Data Models and Design

The big question

Is the relational model and its associated query language (SQL) well suited for OLAP databases?

- Aggregation (sums, averages, totals, ...) are very common in OLAP queries
 - Problem : SQL aggregation quickly runs out of steam.
 - Solution : Data Cube and associated operations (spreadsheets on steroids)
- Relational design is obsessed with normalization
 - Problem : Need to organize data well since all analysis queries cannot be anticipated in advance.
 - Solution : Multi-dimensional fact tables, with hierarchy in dimensions, star-schema design.

Let's start by looking at aggregate queries in SQL ...

An Example ...

Why Multisets?

Duplicates are important for aggregate functions.

The group by clause

```
mysql> select course,
        min(mark),
        max(mark),
        avg(mark)
    from marks
    group by course;
 course | min(mark) | max(mark) | avg(mark) |
    ____+
databases | 88 | 100 | 93.0000 |
 spelling | 3 |
                  100 | 73.5000 |

The having clause

How can we select on the aggregated columns?

```
mysql> select course,
        min(mark),
        max(mark),
        avg(mark)
    from marks
    group by course
    having min(mark) > 60;
 _____+
 course | min(mark) | max(mark) | avg(mark) |
_____+
 databases | 88 | 100 | 93.0000 |
   _____+___
```

Use renaming to make things nicer ...

```
mysql> select course,
         min(mark) as minimum,
         max(mark) as maximum,
         avg(mark) as average
    from marks
    group by course
    having minimum > 60;
  ----+
 course | minimum | maximum | average |
-----+
| databases | 88 | 100 | 93.0000 |
```

- Flat tables are great for processing, but hard for people to read and understand.
- Pivot tables and cross tabulations (spreadsheet terminology) are very useful for presenting data in ways that people can understand.
- SQL does not handle pivot tables and cross tabulations well.

The Data Cube

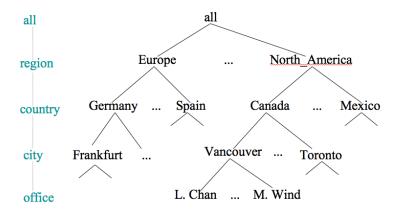

Dimensions: Product, Location, Time

- Data modeled as an *n*-dimensional (hyper-) cube
- Each dimension is associated with a hierarchy
- Each "point" records facts
- Aggregation and cross-tabulation possible along all dimensions
