Java Case Studies

Martin Richards mr@cl.cam.ac.uk

Michaelmas 2003

(Version September 1, 2003)

1 Introduction

These notes contain the source of two Java programs than will be used as case studies in this course. The first is an animation of a sundial designed for a house in norther Ghana and the second is a simple spreadsheet program that is one of the demonstation programs in the Java distribution from Sun.

2 SunDial

2.1 Makefile

```
WWW = /homes/mr/public_html

run:    SunDial.class
    appletviewer SunDial.html

SunDial.class:  SunDial.java
    rm -f *.class
    javac SunDial.java

copy:   clean
    (cd ..; cp -r Sundial/* /homes/mr/Sundial)

pub:    SunDial.class
    (cp -r *.class Makefile $(WWW)/sundial; \
    cp -r SunDial.java $(WWW)/sundial; \
    cp -r SunDial.java $(WWW)/sundial/SunDial.src )

clean:
    rm -f *.class *~
```

2.2 SunDial.html

```
<html>
<body>
<h1>
A Sundial Designed for a House in Damongo, Ghana
</h1>
<p>

<applet code="SunDial.class" width=700 height=500>
Sorry -- your browser does not support java applets
```

```
</applet>

<p>
The source code for this applet is in:
<A HREF="SunDial.java">SunDial.java</A>.

<P>
A current image of the new
<A HREF="http://www.uk.research.att.com/sundial/">sundial</A>
in Pembroke College may be of interest.
Bear in mind that it may not be sunny in Cambridge right now.

</body>
</html>
```

2.3 SunDial.java

```
/*
This program animates a sundial designed for Geraldine's back garden
of a house in Damongo, Ghana.

Re-implemented by: Martin Richards -- (c) November 2002
In its present form it is still incomplete and un polished.

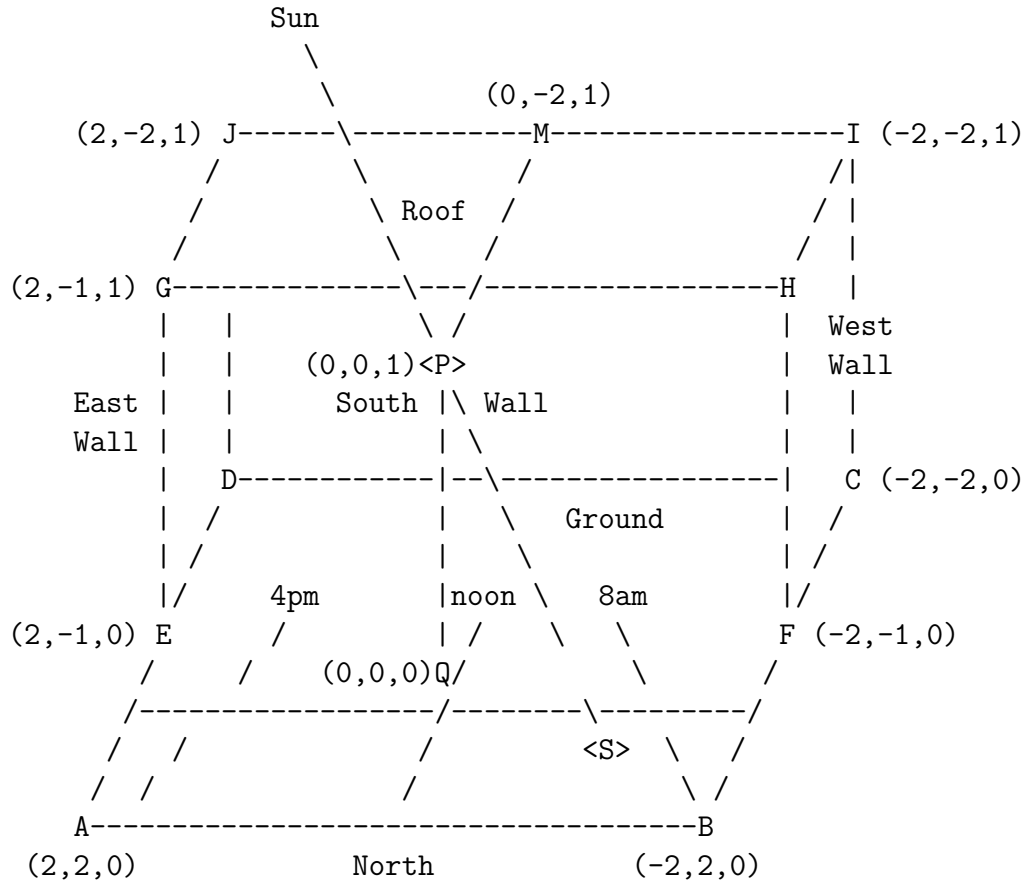
Original implementation using Java 1.0 May 1988
Updated from Java 1.0 to Java 1.1 -- October 2000
Complete re-design for Java 1.4.1 -- October 2002

I gratefully acknowledge Frank King's help with mathematics of
sundials, and I have used the approximation to the equation of time
given in a note by Art Carlson in:
http://www.ipp.mpg.de/~awc/sundial.html

This program was originally implemented using the Sheets Hypertext
System developed by the Gwydion Group at Carnegie Mellon University.

Overview

The setup looks as follows:
```



The x-, y- and z-axes are East, North and Up respectively. The house in Damongo is at latitude 9.08N and longitude 1.81W. Being close to the Grenwich Meridian, the time there is GMT, and since it is close to the equator the sun is high in the sky at midday and can even be vertically overhead.

Points in the diagram have been given names. ABCD are the four corners of the 4x4 square concrete "garden" on the ground, Q is the centre of this square and is taken as the origin of the coordinate system. EDJG, FCIH and DCIJ are the vertices of the east, west and south walls respectively, and GHIJ are the vertices of the roof. M is the mid point of IJ and P is the position vertically above Q where there is a wooden star with a hole to cast a shadow on the ground at point S. Lines painted on the ground allow the position of S to be interpreted as a time of day. With the equation of time correction the result is a time of day accurate to within a minute or two.

The program attempts to follow the MVC (Model-View-Control) style of programming. The java classes used in this program are: SunDial, Model, Viewer, Controls, EyePic, ScrPoint and Point3D.

SunDial

This contains the main program. It initialised the system by creating instances of the Model, the Viewer and the Controller classes and then behaves as the overall controller of the application. It responds to invocations of init, start, stop and destroy that may be called by appletviewer or a browser.

Model

The model contains quantities relating to the physical structure of the scene including the the discription of the house and garden and the position of the sun's shadow (S). It also contains the optional trace of how point S has moved and displayed by the viewer appears as yellow curves on the ground. If the time steps are in days the well known figure of eigth picture is generated illustrating the equation of time.

It receives time updates fron the controller causing it to recompute the location of S and associated values. When anything in the model changes it causes the viewer to repaint the scene.

Viewer

The viewer contains variables and methods used to convert the model into a 2 dimensional image on the screen. It contains fields representing the view point and field of view, as well as methods to paint the scene. In principle, other viewers are possible such as one to write an ASCII representation of the scene to file. Such aleternative viewers are not implemented in this program.

Controls

The controller contains facilities to allow the user to change the current state of the system such as the date and time and the position of the view point. Both keyboard and mouse events are used. The

controller uses a thread to generate a uniform sequence of time updates to cause the animation. The thread runs at low priority so that the user's actions take precedence.

The controller has no variables repesenting the state of the system, preferring to update the state by calling methods of the model and the viewer. It does however have a description of the control panel and methods to act on any control events generated by the user. A painting method is defined for the control panel but called explicitly from the viewer when a new image must be generated. This is so that the controls can overlay the main scene paited by the viewer.

EyePic

This class defines a component that appears in the control panel. Its purpose is to allow the user to line of sight of the view point. The distance of the view point is separately controlled by a scroll bar in the controller panel. The line of sight from the view point to the house is represented by the coordinates (eyeR) of where it passes through the roof level (z=1.0) on its way to the origin (Q=(0,0,0)). This point (eyeD) is a field belonging to the viewer, as is eyeD the distance between the view point and the origin.

ScrPoint

This class is used to represent the integer coordinates of points on the screen. It has two fields x and y but no methods.

Point3

This provides a representation of points in 3 dimensions, together with a collection of useful operations on them. Its methods are: add, sub, mul(by a scalar), innerProd and crossProd. The method cosines calculates the point of intersection of the line from the origin to the point and a unit sphere centred at the origin.
