

## 2007 Paper 10 Question 4

### Programming in C and C++

A C programmer is working with a little-endian machine with 8 bits in a byte and 4 bytes in a word. The compiler supports unaligned access and uses 1, 2 and 4 bytes to store `char`, `short` and `int` respectively. The programmer writes the following definitions (below right) to access values in main memory (below left):

Address	Byte offset				
	0	1	2	3	
0x04	10	00	00	00	<code>int **i=(int **)0x04;</code>
0x08	61	72	62	33	<code>short **pps=(short **)0x1c;</code>
0x0c	33	00	00	00	
0x10	78	0c	00	00	<code>struct i2c {</code>
0x14	08	00	00	00	<code>int i;</code>
0x18	01	00	4c	03	<code>char *c;</code>
0x1c	18	00	00	00	<code>}*p=(struct i2c*)0x10;</code>

(a) Write down the values for the following C expressions:

<code>**i</code>	<code>p-&gt;c[2]</code>	<code>&amp;(*pps)[1]</code>	<code>++p-&gt;i</code>	[8 marks]
------------------	-------------------------	-----------------------------	------------------------	-----------

(b) Explain why the code shown below, when executed, will print the value 420.

```
#include<stdio.h>

#define init_employee(X,Y) {(X),(Y),wage_emp}
typedef struct Employee Em;
struct Employee {int hours,salary;int (*wage)(Em*);};
int wage_emp(Em *ths) {return ths->hours*ths->salary;}

#define init_manager(X,Y,Z) {(X),(Y),wage_man,(Z)}
typedef struct Manager Mn;
struct Manager {int hours,salary;int (*wage)(Mn*);int bonus;};
int wage_man(Mn *ths) {return ths->hours*ths->salary+ths->bonus;}

int main(void) {
    Mn m = init_manager(40,10,20);
    Em *e= (Em *) &m;
    printf("%d\n",e->wage(e));
    return 0;
}
```

[4 marks]

(c) Rewrite the C code shown in part (b) using C++ primitives and give *four* reasons why your C++ solution is better than the C one. [8 marks]
