### Context: Building reliable computer systems

Jérémie Koenig (Yale University)

Algebraic Game Semantics

July 14, 2021 3/20

• • E

In modern computer systems:

- Layers upon layers of complex hardware and software components
- A bug in any one of them could prevent the system from working
- Components may break in subtle ways through their interactions

In modern computer systems:

- Layers upon layers of complex hardware and software components
- A bug in any one of them could prevent the system from working
- Components may break in subtle ways through their interactions

Thankfully, there are ways to control this:

- Precise specifications for each component
- Careful and systematic testing
- Formal verification

## Formal verification of software components

To prove a program correct:

- Start with a model of the programming language
- Make the specification mathematically precise
- Write a proof showing that the program indeed meets the specification

## Formal verification of software components

To prove a program correct:

- Start with a model of the programming language
- Make the specification mathematically precise
- Write a proof showing that the program indeed meets the specification

Mechanizing this process in a proof assistant has many advantages:

- Almost no possibility of mistake in the proof
- Can scale up the methodology to complex programs
- The proof can easily be checked by a third-party (certified software)

Over the past  ${\sim}10$  years, verification has become increasingly tractable:

- Researchers have verified complex components of various kinds
- Industrial-strength verification tools exist

Over the past  $\sim$  10 years, verification has become increasingly tractable:

- Researchers have verified complex components of various kinds
- Industrial-strength verification tools exist

The next step is *end-to-end* verification:

- Until then, bugs can sneak into the "gaps" between correctness proofs
- Solution: use formal specifications as *interfaces* to connect proofs
- Challenge: existing projects use different models and proof methods
- This is by necessity and not by accident

# End-to-end verification using a hierarchy of models

This suggests we should organize semantic models into a *hierarchy*:

- Individual components are verified using specialized models
- Embed these models into increasingly general ones where certified component can be assembled into certified systems

# End-to-end verification using a hierarchy of models

This suggests we should organize semantic models into a *hierarchy*:

- Individual components are verified using specialized models
- Embed these models into increasingly general ones where certified component can be assembled into certified systems

Category theory provides a unified framework to:

- Characterize existing models
- Establish connections between them
- Guide the design of more general ones

# This paper

I will present a very small step in this direction, looking at connections between two important lines of work:

- *Game semantics* expresses the behavior of program components as *strategies* in games derived from their types;
- *Algebraic effects* model computations with side-effects as *terms* in an algebraic theory.

# This paper

I will present a very small step in this direction, looking at connections between two important lines of work:

- *Game semantics* expresses the behavior of program components as *strategies* in games derived from their types;
- *Algebraic effects* model computations with side-effects as *terms* in an algebraic theory.

I will show that:

- Simple strategies can be used to construct interesting models of algebraic effects
- Conversely, we can take inspiration from algebraic effects to characterize these simple strategies categorically.

# This paper

I will present a very small step in this direction, looking at connections between two important lines of work:

- Game semantics expresses the behavior of program components as *strategies* in games derived from their types;
- Algebraic effects model computations with side-effects as *terms* in an algebraic theory.

I will show that:

- Simple strategies can be used to construct interesting models of algebraic effects
- Conversely, we can take inspiration from algebraic effects to characterize these simple strategies categorically.

I hope this correspondence can be extended in the future to formulate a more general algebraic approach to game semantics.

(b) (4) (3) (4)

### Section 2

# Background: Game semantics and algebraic effects

Jérémie Koenig (Yale University)

Algebraic Game Semantics

July 14, 2021 9 / 20

#### **Game Semantics**

Game semantics is a general approach to programming language semantics:

- Types are two-player *games* between a component and its environment.
- Programs of a given type are *strategies* for the corresponding game.

・ロト ・ 同ト ・ ヨト ・ ヨト

#### **Game Semantics**

*Game semantics* is a general approach to programming language semantics:

- Types are two-player *games* between a component and its environment.
- Programs of a given type are *strategies* for the corresponding game.

This approach is very compelling for heterogeneous verification:

- Games provide a very general notion of interface
- "Rely-guarantee" flavor facilitates compositional reasoning

### **Game Semantics**

Game semantics is a general approach to programming language semantics:

- Types are two-player *games* between a component and its environment.
- Programs of a given type are *strategies* for the corresponding game.

This approach is very compelling for heterogeneous verification:

- Games provide a very general notion of interface
- "Rely-guarantee" flavor facilitates compositional reasoning

However there are challenges to overcome:

- Huge variety of constructions for games and strategies
- Often too complex to formalize in a proof assistant
- Existing work rarely focuses on specifications and verification

Algebraic effects address the narrower problem of computational side-effects:

- The available side-effects are given by an algebraic theory
- *Terms* in the theory represent computations, which proceed inwards.
- *Operations* represent effects, their arguments are the possible continuations.

Algebraic effects address the narrower problem of computational side-effects:

- The available side-effects are given by an algebraic theory
- Terms in the theory represent computations, which proceed inwards.
- *Operations* represent effects, their arguments are the possible continuations.

Advantages:

- Composing effect theories is easier than in the monadic approach
- The framework is simple and systematic, grounded in categorical algebra Limitations:
  - Narrower scope than game semantics, less generality

# Algebraic signatures can be read as games

In the algebraic framework, a program with side-effects:

greeting(\*) := (if readbit then print "Hi" else print "Hello"); stop

is modeled in the following way:

 $\Sigma := \{ \text{readbit} : 2, \text{ print}[s] : 1, \text{ done} : 0 \mid s \in \text{string} \}$ t := readbit(print[``Hi"](stop), print[``Hello"](stop))

# Algebraic signatures can be read as games

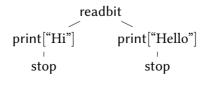

In the algebraic framework, a program with side-effects:

greeting(\*) := (if readbit then print "Hi" else print "Hello"); stop

is modeled in the following way:

$$\Sigma := \{ \text{readbit} : 2, \text{ print}[s] : 1, \text{ done } : 0 \mid s \in \text{string} \}$$
$$t := \text{readbit}(\text{print}[``Hi"](\text{stop}), \text{ print}[``Hello"](\text{stop}))$$

Reading the signature  $\Sigma$  as a game, the term *t* becomes a *strategy tree*:

# Effect signatures

#### Definition (Effect signature)

An *effect signature* is a set *E* of operations together with a map ar :  $E \rightarrow$ **Set** which assigns an *arity set* to each one.

# Effect signatures

#### Definition (Effect signature)

An *effect signature* is a set *E* of operations together with a map ar :  $E \rightarrow$ **Set** which assigns an *arity set* to each one.

#### Definition (Algebraic interpretation)

The *terms* in *E* with variables in the set *X* are defined by the grammar:

$$t \in E^*X ::= \underline{x} \mid \underline{m}(t_n)_{n \in \operatorname{ar}(m)} \qquad (m \in E, \ x \in X)$$

# Effect signatures

#### Definition (Effect signature)

An *effect signature* is a set *E* of operations together with a map ar :  $E \rightarrow$ **Set** which assigns an *arity set* to each one.

#### Definition (Algebraic interpretation)

The *terms* in *E* with variables in the set *X* are defined by the grammar:

$$t \in E^*X ::= \underline{x} \mid \underline{m}(t_n)_{n \in \operatorname{ar}(m)} \qquad (m \in E, \ x \in X)$$

#### Definition (Game interpretation)

The *plays* over an effect signature *E* with results in *X* are defined by the grammar:

$$s \in P_E(X) ::= \underline{x} \mid \underline{m} \mid \underline{m}ns$$
  $(x \in X, m \in E, n \in ar(m))$ 

Jérémie Koenig (Yale University)

4 D F 4 B F 4

# Categorical characterization of terms and strategies

An effect signature can be interpreted as a polynomial endofunctor  $E : \mathbf{Set} \to \mathbf{Set}$  constructing the terms of depth one:

$$EX := \sum_{m \in E} \prod_{n \in \operatorname{ar}(m)} X$$

An *algebra* for *E* is a set *A* with a function  $\alpha : EA \to A$ ; they form a category **Set**<sup>*E*</sup>.

# Categorical characterization of terms and strategies

An effect signature can be interpreted as a polynomial endofunctor  $E : \mathbf{Set} \to \mathbf{Set}$  constructing the terms of depth one:

$$EX := \sum_{m \in E} \prod_{n \in \operatorname{ar}(m)} X$$

An *algebra* for *E* is a set *A* with a function  $\alpha : EA \to A$ ; they form a category **Set**<sup>*E*</sup>.

As is well-known, the "carrier set" functor  $U : \mathbf{Set}^E \to \mathbf{Set}$  has a left adjoint, which maps a set X to the term algebra with carrier set  $E^*X$ .

# Categorical characterization of terms and strategies

An effect signature can be interpreted as a polynomial endofunctor  $E : \mathbf{Set} \to \mathbf{Set}$  constructing the terms of depth one:

$$EX := \sum_{m \in E} \prod_{n \in \operatorname{ar}(m)} X$$

An *algebra* for *E* is a set *A* with a function  $\alpha : EA \to A$ ; they form a category **Set**<sup>*E*</sup>.

As is well-known, the "carrier set" functor  $U : \mathbf{Set}^E \to \mathbf{Set}$  has a left adjoint, which maps a set X to the term algebra with carrier set  $E^*X$ .

By working in a category of directed-complete partial orders, I obtain a similar characterization for the *strategies* over *E*.

## Section 3

### Result: Strategies for algebraic effects

Jérémie Koenig (Yale University)

Algebraic Game Semantics

#### Strategies over an effect signature

イロト イポト イヨト イヨ

# Strategies over an effect signature

#### Definition (Coherent plays)

The *coherence* relation  $\bigcirc \subseteq P_E(X) \times P_E(X)$  is the smallest relation satisfying:

 $\underline{x} \odot \underline{x} \qquad \underline{m} \odot \underline{m} \qquad \underline{m} \odot \underline{m} ns$  $(n_1 = n_2 \Rightarrow s_1 \odot s_2) \Rightarrow \underline{m} n_1 s_1 \odot \underline{m} n_2 s_2$ 

◆□ ▶ ◆□ ▶ ◆ □ ▶ ◆ □ ▶ ◆ □ ◆ ○ ○ ○

# Strategies over an effect signature

#### Definition (Coherent plays)

The *coherence* relation  $\Box \subseteq P_E(X) \times P_E(X)$  is the smallest relation satisfying:

$$\begin{array}{cccc} \underline{x} \odot \underline{x} & \underline{m} \odot \underline{m} & \underline{m} \odot \underline{m} ns \\ (n_1 = n_2 \Rightarrow s_1 \odot s_2) \Rightarrow \underline{m} n_1 s_1 \odot \underline{m} n_2 s_2 \end{array}$$

#### Definition (Effect strategy)

A strategy  $\sigma \in S_E(X)$  over a signature *E* with results in *X* is a prefix-closed set  $\sigma \subseteq P_E(X)$  of pairwise coherent plays.

> < E > < E >

# Algebraic characterization of strategies

Strategies under set inclusion form a pointed directed-complete partial order:

- The empty strategy is the least element
- Unions of directed sets of strategies preserve the coherence condition

# Algebraic characterization of strategies

Strategies under set inclusion form a pointed directed-complete partial order:

- The empty strategy is the least element
- Unions of directed sets of strategies preserve the coherence condition

It turns out the strategies for *E* can be characterized as free algebras in **DCPO** $_{\perp !}$ , where the effect signature *E* is interpreted as the endofunctor:

$$\hat{E}X := \bigoplus_{m \in E} \left(\prod_{n \in \operatorname{ar}(m)} X\right)_{\perp}$$

# Algebraic characterization of strategies

Strategies under set inclusion form a pointed directed-complete partial order:

- The empty strategy is the least element
- Unions of directed sets of strategies preserve the coherence condition

It turns out the strategies for *E* can be characterized as free algebras in **DCPO** $_{\perp !}$ , where the effect signature *E* is interpreted as the endofunctor:

$$\hat{E}X := \bigoplus_{m \in E} \left(\prod_{n \in \operatorname{ar}(m)} X\right)_{\perp}$$

#### Theorem

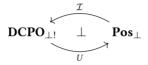

The forgetful functor  $\hat{U}$  : **DCPO** $_{\perp!}^{\hat{E}} \rightarrow$  **Set** has a left adjoint. The pointed dcpo  $S_E(X)$  carries the corresponding  $\hat{E}$ -algebra.

Jérémie Koenig (Yale University)

Algebraic Game Semantics

## Strategies are ideal completions of terms

The *ideal completion*  $\mathcal{I}$  constructs the free dcpo on a poset:

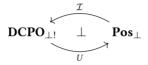

If we order terms with variables in  $X_{\perp}$  using the rules

$$\frac{1}{\underline{\bot} \sqsubseteq t} \qquad \frac{\underline{x} \sqsubseteq \underline{x}}{\underline{x} \sqsubseteq \underline{x}} \qquad \frac{\forall n \in \operatorname{ar}(m) \cdot t_n \sqsubseteq t'_n}{\underline{m}(t_n)_{n \in \operatorname{ar}(m)} \sqsubseteq \underline{m}(t'_n)_{n \in \operatorname{ar}(m)}} \quad ,$$

this provides an alternative construction of strategies as  $\mathcal{I}E^*(X_{\perp})$ .

## Strategies are ideal completions of terms

The *ideal completion*  $\mathcal{I}$  constructs the free dcpo on a poset:

If we order terms with variables in  $X_{\perp}$  using the rules

$$\underline{\underline{}} \sqsubseteq \underline{t} \qquad \underline{\underline{x}} \sqsubseteq \underline{x} \qquad \frac{\forall n \in \operatorname{ar}(m) \cdot t_n \sqsubseteq t'_n}{\underline{m}(t_n)_{n \in \operatorname{ar}(m)} \sqsubseteq \underline{m}(t'_n)_{n \in \operatorname{ar}(m)}} \quad ,$$

this provides an alternative construction of strategies as  $\mathcal{I}E^*(X_{\perp})$ .

#### Theorem

The following partial orders are isomorphic:  $S_E(X) \cong \mathcal{I}E^*(X_{\perp}) \cong \mu Y \cdot \hat{E}Y \oplus X_{\perp}$ 

Jérémie Koenig (Yale University)

Algebraic effects and game semantics have themes in common, but they look at them very differently.

I believe we can build on the correspondence I have presented to confront these point of views in interesting ways.

For example:

• Generalizing to multi-sorted signatures allows for richer games. This could serve as a common low-level algebraic grounding for a variety of sequential game semantics models.

Algebraic effects and game semantics have themes in common, but they look at them very differently.

I believe we can build on the correspondence I have presented to confront these point of views in interesting ways.

For example:

- Generalizing to multi-sorted signatures allows for richer games. This could serve as a common low-level algebraic grounding for a variety of sequential game semantics models.
- Effect signatures and natural transformations  $\eta_X : EX \to FX \in \mathbf{Set}$  form a symmetric monoidal closed category. Endofunctor composition and the free monad construction can be defined directly on signatures. We can carry out a version of Reddy's *object-based semantics* in this setting.
