[For hol98 Taupo-5]

The HOL System REFERENCE

University of Cambridge

DSTO

SRI International

Preface

This volume is the reference manual for the HOL system. It is one of three documents making up the documentation for HOL:

- (i) TUTORIAL: a tutorial introduction to HOL, with case studies.
- (ii) *DESCRIPTION*: a description of higher order logic, the ML programming language, and theorem proving methods in the HOL system;
- (iii) REFERENCE: the reference documentation of the tools available in HOL.

These three documents will be referred to by the short names (in small slanted capitals) given above.

This document, *REFERENCE*, provides documentation on all the pre-defined ML variable bindings in the HOL system. These include: general-purpose functions, such as ML functions for list processing, arithmetic, input/output, and interface configuration; functions for processing the types and terms of the HOL logic, for setting up theories, and for using the subgoal package; primitive and derived forward inference rules; tactics and tacticals; and pre-proved built-in theorems.

The manual entries for these ML identifiers are divided into two chapters. The first chapter is an alphabetical sequence of manual entries for all ML identifiers in the system except those identifiers that are bound to theorems. The theorems are listed in the second chapter, roughly grouped into sections based on subject matter.

The *REFERENCE* volume is purely for reference and browsing. It is generated from the same database that is used by the help system. For an introduction to the HOL system, see *TUTORIAL*; for a systematic presentation, see *DESCRIPTION*.

Acknowledgements

First edition

The three volumes *TUTORIAL*, *DESCRIPTION* and *REFERENCE* were produced at the Cambridge Research Center of SRI International with the support of DSTO Australia.

The HOL documentation project was managed by Mike Gordon, who also wrote parts of *DESCRIPTION* and *TUTORIAL* using material based on an early paper describing the HOL system¹ and *The ML Handbook*². Other contributers to *DESCRIPTION* incude Avra Cohn, who contributed material on theorems, rules, conversions and tactics, and also composed the index (which was typeset by Juanito Camilleri); Tom Melham, who wrote the sections describing type definitions, the concrete type package and the 'resolution' tactics; and Andy Pitts, who devised the set-theoretic semantics of the HOL logic and wrote the material describing it.

The original document design used $\mathbb{M}_{E}X$ macros supplied by Elsa Gunter, Tom Melham and Larry Paulson. The typesetting of all three volumes was managed by Tom Melham. The cover design is by Arnold Smith, who used a photograph of a 'snow watching lantern' taken by Avra Cohn (in whose garden the original object resides). John Van Tassel composed the $\mathbb{M}_{E}X$ picture of the lantern.

Many people other than those listed above have contributed to the HOL documentation effort, either by providing material, or by sending lists of errors in the first edition. Thanks to everyone who helped, and thanks to DSTO and SRI for their generous support.

Later editions

The second edition of *REFERENCE* was a joint effort by the Cambridge HOL group.

The third edition of all three volumes represents a wide-ranging and still incomplete revision of material written for HOL88 so that it applies to the hol98 system a decade later. The third edition has been prepared by Konrad Slind and Michael Norrish.

Pre-defined ML Identifiers

This chapter provides manual entries for all the pre-defined ML identifiers in the HOL system, except the identifiers that are bound to pre-proved theorems (for these, see chapter two). These include: general-purpose functions, such as functions for list processing, arithmetic, input/output, and interface configuration; functions for processing the types and terms of the HOL logic, for setting up theories, and for using the subgoal package; primitive and derived forward inference rules; and tactics and tacticals. The arrangement is alphabetical.

##

Lib.## : ('a -> 'b) * ('c -> 'd) -> 'a * 'c -> 'b * 'd

Synopsis

Maps a pair of functions through a pair.

Description

is an infix operator such that the call (f ## g) (x, y) returns the value (f x, g y).

Failure

Never fails.

Example

- ((fn x => x + 1) ## not) (3, false); > val it = (4, true) : int * bool

See also

B, C, I, K, S, W.

++

simpLib.++ : simpset * ssdata -> simpset

Synopsis

Augments simpsets with ssdata values.

Description

The ++ function combines its two arguments and creates a new simpset. This is a way of creating simpsets that are tailored to the particular simplification task at hand.

Failure

Never fails.

Example

Here we add the UNWIND_ss ssdata value to the pure_ss simpset to exploit the former's point-wise elimination conversions.

Comments

The ++ identifier is not an infix by default, and so needs to be declared as such at the ML top-level loop, e.g.:

- infix ++; > infix 0 ++

See also

mk_simpset, rewrites, SIMP_CONV, bool_ss, UNWIND_ss

ABS

ABS : (term \rightarrow thm \rightarrow thm)

Synopsis

Abstracts both sides of an equation.

Description

A | - t1 = t2----- ABS x $A | - (\x.t1) = (\x.t2)$

[Where x is not free in A]

Failure

If the theorem is not an equation, or if the variable x is free in the assumptions A.

2

Example

See also ETA_CONV, EXT, MK_ABS.

ABS_CONV

ABS_CONV : (conv -> conv)

Synopsis

Applies a conversion to the body of an abstraction.

Description

If c is a conversion that maps a term tm to the theorem |-tm = tm', then the conversion ABS_CONV c maps abstractions of the form x.tm to theorems of the form:

|-(x.tm) = (x.tm')

That is, ABS_CONV c "\x.t" applies c to the body of the abstraction "\x.t".

Failure

ABS_CONV c tm fails if tm is not an abstraction or if tm has the form "\x.t" but the conversion c fails when applied to the term t. The function returned by ABS_CONV c may also fail if the ML function c:term->thm is not, in fact, a conversion (i.e. a function that maps a term M to a theorem |-M = N).

Example

```
- let val M = Parse.Term '\x. 1 = x'
in
ABS_CONV SYM_CONV M
end;
```

```
|-(x. 1 = x) = (x. x = 1)
```

See also

RAND_CONV, RATOR_CONV, SUB_CONV.

ACCEPT_TAC

ACCEPT_TAC : thm_tactic

Synopsis

Solves a goal if supplied with the desired theorem (up to alpha-conversion).

Description

ACCEPT_TAC maps a given theorem th to a tactic that solves any goal whose conclusion is alpha-convertible to the conclusion of th.

Failure

ACCEPT_TAC th (A,g) fails if the term g is not alpha-convertible to the conclusion of the supplied theorem th.

Example

ACCEPT_TAC applied to the axiom

BOOL_CASES_AX = $|-!t.(t = T) \setminus / (t = F)$

will solve the goal

?- !x. (x = T) \setminus / (x = F)

but will fail on the goal

?- !x. $(x = F) \setminus / (x = T)$

Uses

Used for completing proofs by supplying an existing theorem, such as an axiom, or a lemma already proved.

See also

MATCH_ACCEPT_TAC.

aconv

```
aconv : (term -> term -> bool)
```

Synopsis

Tests for alpha-convertibility of terms.

Description

When applied to two terms, aconv returns true if they are alpha-convertible, and false otherwise.

Failure

Never fails.

Example

A simple case of alpha-convertibility is the renaming of a single quantified variable:

```
- let val M = Parse.Term '?x. x = T'
val N = Parse.Term '?y. y = T'
in
aconv M N
end;
true : bool
```

See also ALPHA, ALPHA_CONV.

AC_CONV

```
AC_CONV : ((thm \# thm) -> conv)
```

Synopsis

Proves equality of terms using associative and commutative laws.

Description

Suppose _ is a function, which is assumed to be infix in the following syntax, and ath and cth are theorems expressing its associativity and commutativity; they must be of the following form, except that any free variables may have arbitrary names and may be universally quantified:

```
ath = |- m _ (n _ p) = (m _ n) _ p
cth = |- m _ n = n _ m
```

Then the conversion AC_CONV(ath,cth) will prove equations whose left and right sides can be made identical using these associative and commutative laws.

Failure

Fails if the associative or commutative law has an invalid form, or if the term is not an equation between AC-equivalent terms.

Example

Comments

Note that the preproved associative and commutative laws for the operators +, *, / and / are already in the right form to give to AC_CONV.

See also

SYM_CONV.

ADD_ASSUM

ADD_ASSUM : (term \rightarrow thm \rightarrow thm)

Synopsis

Adds an assumption to a theorem.

Description

When applied to a boolean term s and a theorem A |-t, the inference rule ADD_ASSUM returns the theorem A u {s} |-t.

A |- t ----- ADD_ASSUM s A u {s} |- t

ADD_ASSUM performs straightforward set union with the new assumption; it checks for identical assumptions, but not for alpha-equivalent ones. The position at which the new assumption is inserted into the assumption list should not be relied on.

Failure

Fails unless the given term has type bool.

See also ASSUME, UNDISCH.

add_bare_numeral_form

Parse.add_bare_numeral_form : (char * string option) -> unit

Synopsis

Adds support for annotated numerals to the parser/pretty-printer.

Description

The function add_bare_numeral_form allows the user to give special meaning to strings of digits that are suffixed with single characters. A call to this function with pair argument (c, s) adds c as a possible suffix. Subsequently, if a sequence of digits is parsed, and it has the character c directly after the digits, then the natural number corresponding to these digits is made the argument of the "map function" corresponding to s.

This map function is computed as follows: if the s option value is NONE, then the function is considered to be the identity and never really appears; the digits denote a natural number. If the value of s is SOME s', then the parser translates the string to an application of s' to the natural number denoted by the digits.

Failure

Fails if the suffix character is not a letter.

Example

The following function, binary_of, defined with equations:

```
val bthm =
    |- binary_of n = if n = 0 then 0
        else n MOD 10 + 2 * binary_of (n DIV 10) : Thm.thm
```

can be used to convert numbers whose decimal notation is x, to numbers whose binary notation is x (as long as x only involves zeroes and ones).

The following call to add_bare_numeral_form then sets up a numeral form that could be used by users wanting to deal with binary numbers:

Uses

If one has a range of values that are usefully indexed by natural numbers, the function add_bare_numeral_form provides a syntactically convenient way of reading and writing these values. If there are other functions in the range type such that the mapping function is a homomorphism from the natural numbers, then add_numeral_form could be used, and the appropriate operators (+, * etc) overloaded.

See also

add_numeral_form

add_implicit_rewrites

Rewrite.add_implicit_rewrites: thm list -> unit

Synopsis

Augments the built-in database of simplifications automatically included in rewriting.

Uses

Used to build up the power of the built-in simplification set.

See also

base_rewrites, set_implicit_rewrites.

add_infix

```
Parse.add_infix : string * int * HOLgrammars.associativity -> unit
```

Synopsis

Adds a string as an infix with the given precedence and associativity to the term grammar.

Description

This function adds the given string to the global term grammar such that the string

<str1> s <str2>

will be parsed as

s <t1> <t2>

where <str1> and <str2> have been parsed to two terms <t1> and <t2>. The parsing process does not pay any attention to whether or not s corresponds to a constant or not. This resolution happens later in the parse, and will result in either a constant or a variable with name s. In fact, if this name is overloaded, the eventual term generated may have a constant of quite a different name again; the resolution of overloading comes as a separate phase (see the entry for overload_on).

Failure

add_infix fails if the precedence level chosen for the new infix is the same as a different type of grammar rule (e.g., suffix or binder), or if the specified precedence level has infixes already but of a different associativity.

It is also possible that the choice of string s will result in subsequent attempts to call the term parser failing due to precedence conflicts.

Example

Though we may not have + defined as a constant, we can still define it as an infix for

the purposes of printing and parsing:

```
- add_infix ("+", 500, HOLgrammars.LEFT);
> val it = () : unit
- val t = Term'x + y';
<<HOL message: inventing new type variable names: 'a, 'b, 'c.>>
> val t = 'x + y' : Term.term
```

We can confirm that this new infix has indeed been parsed that way by taking the resulting term apart:

```
- dest_comb t;
> val it = {Rand = 'y', Rator = '$+ x'} :
        {Rand : Term.term, Rator : Term.term}
```

With its new status, + has to be "quoted" with a dollar-sign if we wish to use it in a position where it is not an infix, as in the binding list of an abstraction:

The generation of three new type variables in the examples above emphasises the fact that the terms in the first example and the body of the second are really no different from $f \times y$ (where f is a variableaddition from arithmeticTheory. The new + infix is left

associative:

```
- Term'x + y + z';
<<HOL message: inventing new type variable names: 'a, 'b.>>
> val it = 'x + y + z' : Term.term
- dest_comb it;
> val it =
    {Rand = 'z', Rator = '$+ (x + y)'}
    : {Rand : Term.term, Rator : Term.term}
```

It is also more tightly binding than / (which has precedence 400 by default):

```
- Term'p /\ q + r';
<<HOL message: inventing new type variable names: 'a, 'b.>>
> val it = 'p /\ q + r' : Term.term
- dest_comb it;
> val it =
    {Rand = 'q + r', Rator = '$/\ p'}
    : {Rand : Term.term, Rator : Term.term}
```

An attempt to define a right associative operator at the same level fails:

Similarly we can't define an infix at level 900, because this is where the (true prefix) rule for logical negation (~) is.

```
- Lib.try add_infix("-", 900, HOLgrammars.RIGHT);
Exception raised at Parse.add_infix:
Grammar Error: Attempt to have different forms at same level
! Uncaught exception:
! HOL_ERR <poly>
```

Finally, an attempt to have a second + infix at a different precedence level causes grief

when we later attempt to use the parser:

```
- add_infix("+", 400, HOLgrammars.RIGHT);
> val it = () : unit
- Term'p + q';
! Uncaught exception:
! HOL_ERR <poly>
- Lib.try Term'p + q';
Exception raised at Parse.Term:
Grammar introduces precedence conflict between tokens + and +
! Uncaught exception:
! HOL_ERR <poly>
```

Uses

Most use of infixes will want to have them associated with a particular constant in which case the definitional principles (new_infixl_definition etc) are more likely to be appropriate. However, a development of a theory of abstract algebra may well want to have infix variables such as + above.

Comments

As with other functions in the Parse structure, there is a companion temp_add_infix function, which has the same effect on the global grammar, but which does not cause this effect to persist when the current theory is exported.

See also

```
add_binder, add_rule, add_listform, Term.
```

add_listform

```
Parse.add_listform :
    {separator : string, leftdelim : string, rightdelim : string,
        cons : string, nilstr : string} -> unit
```

Synopsis

Adds a "list-form" to the built-in grammar, allowing the parsing of strings such as [a; b; c] and {}.

Description

The add_listform function allows the user to augment the HOL parser with rules so that it can turn a string of the form

<ld> str1 <sep> str2 <sep> ... strn <rd>

into the term

<cons> t1 (<cons> t2 ... (<cons> tn <nilstr>))

where <ld> is the left delimiter string, <rd> the right delimiter, and <sep> is the separator string from the fields of the record argument to the function. The various stri are strings representing the ti terms. Further, the grammar will also parse <ld> <rd> into <nilstr>.

In common with the add_rule function, there is no requirement that the cons and nilstr fields be the names of constants; the parser/grammar combination will generate variables with these names if there are no corresponding constants.

The HOL pretty-printer is simultaneously aware of the new rule, and terms of the forms above will print appropriately.

Failure

Should never fail itself, but subsequent calls to the term parser may well fail if the strings chosen for the various fields above introduce precedence conflicts. For example, it will almost always be impossible to use left and right delimiters that are already present in the grammar, unless they are there as the left and right parts of a closefix.

Example

The definition of the "list-form" for lists in the HOL distribution is:

while the set syntax is defined similarly:

Uses

Used to make sequential term structures print and parse more pleasingly.

Comments

As with other parsing functions, there is a temp_add_listform version of this function, which has the same effect on the global grammar, but which does not cause this effect to persist when the current theory is exported.

See also

add_rule.

add_numeral_form

Parse.add_numeral_form : (char * string option) -> unit

Synopsis

Adds support for numerals of differing types to the parser/pretty-printer.

Description

This function allows the user to extend HOL's parser and pretty-printer so that they recognise and print numerals. A numeral in this context is a string of digits. Each such string corresponds to a natural number (i.e., the HOL type num) but add_numeral_form allows for numerals to stand for values in other types as well.

A call to $add_numeral_form(c,s)$ augments the global term grammar in two ways. Firstly, in common with the function $add_bare_numeral_form$ (q.v.), it allows the user to write a single letter suffix after a numeral (the argument c). The presence of this character specifies s as the "injection function" which is to be applied to the natural number denoted by the preceding digits.

Secondly, the constant denoted by the s argument is overloaded to be one of the possible resolutions of the overloaded operator &. When a numeral doesn't have a character suffix, this means that it has been made an argument to the function fromNum, and so might take on different types, depending on the context.

Failure

Fails if arithmeticTheory is not loaded, as this is where the basic constants implementing natural number numerals are defined. Also fails if there is no constant with the given name, or if it doesn't have type ':num -> 'a' for some 'a. Fails if add_bare_numeral_form would also fail on this input.

Example

The natural numbers are given numeral forms as follows:

val _ = add_numeral_form (#"n", NONE);

This is done in arithmeticTheory so that after it is loaded, one can write numerals and have them parse (and print) as natural numbers. However, later in the development, in

integerTheory, numeral forms for integers are also introduced:

```
val _ = add_numeral_form(#"i", SOME "int_of_num");
```

Here int_of_num is the name of the function which injects natural numbers into integers. After this call is made, numeral strings can be treated as integers or natural numbers, depending on the context.

```
- load "integerTheory";
> val it = () : unit
- Term'3';
<<HOL message: more than one resolution of overloading was possible.>>
> val it = '3' : Term.term
- type_of it;
> val it = ':int' : Type.hol_type
```

The parser has chosen to give the string "3" integer type (it will prefer the most recently specified possibility, in common with overloading in general). However, numerals can appear with natural number type in appropriate contexts:

- Term'(SUC 3, 4 + ~x)';
> val it = '(SUC 3,4 + ~x)' : Term.term
- type_of it;
> val it = ':num # int' : Type.hol_type

Moreover, one can always use the character suffixes to absolutely specify the type of the numeral form:

```
- Term'f 3 /\ p';
<<HOL message: more than one resolution of overloading was possible.>>
> val it = 'f 3 /\ p' : Term.term
- Term'f 3n /\ p';
> val it = 'f 3 /\ p' : Term.term
```

Comments

Overloading on too many numeral forms is a sure recipe for confusion.

See also

add_bare_numeral_form, show_numeral_types

add_rule

```
Parse.add_rule :
    {term_name : string, fixity : fixity,
    pp_elements: term_grammar.pp_element list,
    paren_style : term_grammar.ParenStyle,
    block_style : term_grammar.PhraseBlockStyle *
        term_grammar.block_info} -> unit
```

Synopsis

Adds a parsing/printing rule to the global grammar.

Description

The function add_rule is a fundamental method for adding parsing (and thus printing) rules to the global term grammar that sits behind the functions Term and --, and the pretty-printer installed for terms. It is used to for everything except the addition of list-forms, for which refer to the entry for add_listform.

There are five components in the record argument to add_rule. The term_name component is the name of the term (whether a constant or a variable) that will be generated at the head of the function application. Thus, the term_name component when specifying parsing for conditional expressions is COND.

The following values (all in structure Parse) are useful for constructing fixity values:

val	LEFT RIGHT NONASSOC	:	HOLgrammars.associativity HOLgrammars.associativity HOLgrammars.associativity
val	Prefix	:	fixity
val	Binder	:	fixity
val	Closefix	:	fixity
val	Infixl	:	int -> fixity
val	Infixr	:	int -> fixity
val	Infix	:	HOLgrammars.associativity * int -> fixity
val	TruePrefix	:	int -> fixity
val	Suffix	:	int -> fixity

The Prefix fixity has an unfortunate name, as it is a fixity corresponding to no special treatment. In fact, when a Prefix fixity is specified, the add_rule function performs no action. When an element list is meant to form a genuine prefix, the TruePrefix fixity must be used instead, as is done below in the conditional expression example and as is

also done with ~ (logical negation). The Prefix fixity is useful elsewhere, in situations where standard interfaces require fixities to be provided, but where the user may wish to leave an identifier as a normal symbol.

The Binder fixity is for binders such as universal and existential quantifiers (! and ?). Binders can actually be seen as (true) prefixes (should '!x. p / q' be parsed as '(!x. p) / q' or as '!x. (p / q)'?), but the add_rule interface only allows binders to be added at the one level (the weakest in the grammar). Further, when binders are added using this interface, all elements of the record apart from the term_name are ignored, so the name of the binder must be the same as the string that is parsed and printed (but see also restricted quantifiers: associate_restriction).

The remaining fixities all cause add_rule to pay due heed to the pp_elements ("parsing/printing elements") component of the record. As far as parsing is concerned, the only important elements are TOK and TM values, of the following types:

val TM : term_grammar.pp_element val TOK : string -> term_grammar.pp_element

The TM value corresponds to a "hole" where a sub-term is possible. The TOK value corresponds to a piece of concrete syntax, a string that is required when parsing, and which will appear when printing. The sequence of pp_elements specified in the record passed to add_rule specifies the "kernel" syntax of an operator in the grammar. The "kernel" of a rule is extended (or not) by additional sub-terms depending on the fixity type, thus:

Closefix	:	[Kernel]	(* no external arguments *)
TruePrefix	:	[Kernel] _	(* an argument to the right *)
Suffix	:	_ [Kernel]	(* an argument to the left *)
Infix	:	_ [Kernel] _	(* arguments on both sides *)

Thus simple infixes, suffixes and prefixes would have singleton pp_element lists, consisting of just the symbol desired. More complicated mix-fix syntax can be constructed by identifying whether or not sub-term arguments exist beyond the kernel of concrete syntax. For example, syntax for the evaluation relation of an operational semantics $(_ | - _ - - > _)$ is an infix with a kernel delimited by | - and - > tokens. Syntax for denotation brackets $[| _ |]$ is a closefix with one internal argument in the kernel.

The remaining sorts of possible pp_element values are concerned with pretty-printing. (The basic scheme is implemented on top of a standard Oppen-style pretty-printing

package.) They are

```
(* where
     type term_grammar.block_info = PP.break_style * int
*)
val BreakSpace : (int * int) -> term_grammar.pp_element
val HardSpace : int -> term_grammar.pp_element
val BeginFinalBlock : term_grammar.block_info -> term_grammar.pp_element
val EndInitialBlock : term_grammar.block_info -> term_grammar.pp_element
val PPBlock : term_grammar.pp_element list * term_grammar.block_info
              -> term_grammar.pp_element
val OnlyIfNecessary : term_grammar.ParenStyle
val ParoundName : term_grammar.ParenStyle
val ParoundPrec : term_grammar.ParenStyle
val Always : term_grammar.ParenStyle
val AroundEachPhrase : term_grammar.PhraseBlockStyle
                     : term_grammar.PhraseBlockStyle
val AroundSamePrec
val AroundSameName
                     : term_grammar.PhraseBlockStyle
```

The two spacing values provide ways of specifying white-space should be added when terms are printed. Use of HardSpace n results in n spaces being added to the term whatever the context. On the other hand, BreakSpace(m,n) results in a break of width m spaces unless this makes the current line too wide, in which case a line-break will occur, and the next line will be indented an extra n spaces.

For example, the add_infix function (q.v.) is implemented in terms of add_rule in such a way that a single token infix s, has a pp_element list of

[HardSpace 1, TOK s, BreakSpace(1,0)]

This results in chains of infixes (such as those that occur with conjunctions) that break so as to leave the infix on the right hand side of the line. Under this constraint, printing can't break so as to put the infix symbol on the start of a line, because that would imply that the HardSpace had in fact been broken. (Consequently, if a change to this behaviour is desired, there is no global way of effecting it, but one can do it on an infix-by-infix basis by deleting the given rule (see, for example, remove_termtok) and then "putting it back" with different pretty-printing constraints.)

The PPBlock function allows the specification of nested blocks (blocks in the Oppen pretty-printing sense) within the list of pp_elements. Because there are sub-terms in all but the Closefix fixities that occur beyond the scope of the pp_element list, the BeginFinalBlock and EndInitialBlock functions can also be used to indicate the boundary of blocks whose outer extent is the term beyond the kernel represented by the

pp_element list. There is an example of this below.

The possible ParenStyle values describe when parentheses should be added to terms. The OnlyIfNecessary value will cause parentheses to be added only when required to disambiguate syntax. The ParoundName will cause parentheses to be added if necessary, or where the head symbol has the given term_name and where this term is not the argument of a function with the same head name. This style of parenthesisation is used with tuples, for example. The ParoundPrec value is similar, but causes parentheses to be added when the term is the argument to a function with a different precedence level. Finally, the Always value causes parentheses always to be added.

The PhraseBlockStyle values describe when pretty-printing blocks involving this term should be entered. The AroundEachPhrase style causes a pretty-printing block to be created around each term. This is not appropriate for operators such as conjunction however, where all of the arguments to the conjunctions in a list are more pleasingly thought of as being at the same level. This effect is gained by specifying either AroundSamePrec or AroundSameName. The former will cause the creation of a new block for the phrase if it is at a different precedence level from its parent, while the latter creates the block if the parent name is not the same. The former is appropriate for + and – which are at the same precedence level, while the latter is appropriate for /\.

Failure

This function will fail if the pp_element list does not have TOK values at the beginning and the end of the list, or if there are two adjacent TM values in the list. It will fail if the rule specifies a fixity with a precedence, and if that precedence level in the grammar is already taken by rules with a different sort of fixity.

Example

There are two conditional expression syntaxes defined in the theory bool. The first is the traditional HOL88/90 syntax. Because the syntax involves "dangling" terms to the left and right, it is an infix (and one of very weak precedence at that).

The second rule added uses the more familiar if-then-else syntax. Here there is only a "dangling" term to the right of the construction, so this rule's fixity is of type TruePrefix.

(If the rule was made a Closefix, strings such as 'if P then Q else R' would still parse, but so too would 'if P then Q else'.) This example also illustrates the use of blocks within rules to improve pretty-printing.

Note that the above form is not that actually used in the system. As written, it allows for pretty-printing some expressions as:

```
if P then
<very long term> else Q
```

because the block_style is INCONSISTENT.

The pretty-printer prefers later rules over earlier rules by default (though this choice can be changed with prefer_form_with_tok (q.v.)), so conditional expressions print using the if-then-else syntax rather than the $_=>_____$ syntax.

Uses

For making pretty concrete syntax possible.

Comments

Because adding new rules to the grammar may result in precedence conflicts in the operator-precedence matrix, it is as well with interactive use to test the Term parser immediately after adding a new rule, as it is only with this call that the precedence matrix is built.

As with other functions in the Parse structure, there is a companion temp_add_rule function, which has the same effect on the global grammar, but which does not cause this effect to persist when the current theory is exported.

The Prefix/TruePrefix situation may be transitory. It has the advantage of maintaining a deal of backwards compatibility, but at the cost of confusing the terminology. Where the Prefix value is acceptable, the fixity type should be replaced by a fixity option type to better reflect the semantics of what is really happening.

An Isabelle-style concrete syntax for specifying rules would probably be desirable as it would conceal the complexity of the above from most users.

See also

add_listform, add_infix, prefer_form_with_tok, remove_rules_for_term.

allowed_term_constant

Lexis.allowed_term_constant : string -> bool

Synopsis

Tests if a string has a permissible name for a term constant.

Description

When applied to a string, allowed_term_constant returns true if the string is a permissible constant name for a term, that is, if it is an identifier (see the DESCRIPTION for more details), and false otherwise.

Failure

Never fails.

Example

The following gives a sample of some allowed and disallowed constant names:

```
- map Lexis.allowed_term_constant ["pi", "@", "a name", "+++++", "10"];
> val it = [true, true, false, true, false] : bool list
```

Comments

Note that this function only performs a lexical test; it does not check whether there is already a constant of that name in the current theory.

See also

```
constants, is_constant, new_alphanum, new_special_symbol, special_symbols,
allowed_type_constant.
```

allowed_type_constant

Lexis.allowed_type_constant : string -> bool

Synopsis

Tests if a string has a permissible name for a type constant.

Description

When applied to a string, allowed_term_constant returns true if the string is a permissible constant name for a type operator, and false otherwise.

Failure

Never fails.

Example

The following gives a sample of some allowed and disallowed names for type operators:

- map Lexis.allowed_type_constant ["list", "'a", "fun", "->", "#", "fun2"]; > val it = [true, false, true, false, false, true] : bool list

Comments

Note that this function only performs a lexical test; it does not check whether there is already a type operator of that name in the current theory.

See also

allowed_term_constant

ALL_CONV

ALL_CONV : conv

Synopsis

Conversion that always succeeds and leaves a term unchanged.

Description

When applied to a term ''t'', the conversion ALL_CONV returns the theorem |-t = t.

Failure

Never fails.

Uses Identity element for THENC.

See also

NO_CONV, REFL.

22

ALL_TAC

ALL_TAC : tactic

Synopsis

Passes on a goal unchanged.

Description

ALL_TAC applied to a goal g simply produces the subgoal list [g]. It is the identity for the THEN tactical.

Failure

Never fails.

Example

The tactic INDUCT_TAC THENL [ALL_TAC;tac], applied to a goal g, applies INDUCT_TAC to g to give a basis and step subgoal; it then returns the basis unchanged, along with the subgoals produced by applying tac to the step.

Uses

Used to write tacticals such as REPEAT. Also, it is often used as a place-holder in building compound tactics using tacticals such as THENL.

See also

NO_TAC, REPEAT, THENL.

ALL_THEN

ALL_THEN : thm_tactical

Synopsis

Passes a theorem unchanged to a theorem-tactic.

Description

For any theorem-tactic ttac and theorem th, the application ALL_THEN ttac th results simply in ttac th, that is, the theorem is passed unchanged to the theorem-tactic. ALL_THEN is the identity theorem-tactical.

Failure

The application of ALL_THEN to a theorem-tactic never fails. The resulting theorem-tactic fails under exactly the same conditions as the original one.

Uses

Writing compound tactics or tacticals, e.g. terminating list iterations of theorem-tacticals.

See also

ALL_TAC, FAIL_TAC, NO_TAC, NO_THEN, THEN_TCL, ORELSE_TCL.

ALPHA

ALPHA : term -> term -> thm

Synopsis

Proves equality of alpha-equivalent terms.

Description

When applied to a pair of terms t1 and t1' which are alpha-equivalent, ALPHA returns the theorem |-t1 = t1'.

----- ALPHA t1 t1' |- t1 = t1'

Failure

Fails unless the terms provided are alpha-equivalent.

Example

```
- let val M = Term'!x:num. x = x'
val N = Term'!y:num. y = y'
in
ALPHA M N
end;
```

> val it = |-(!x. x = x) = (!y. y = y) : Thm.thm

See also

aconv, ALPHA_CONV, GEN_ALPHA_CONV.

24

ALPHA_CONV

ALPHA_CONV : (term -> conv)

Synopsis

Renames the bound variable of a lambda-abstraction.

Description

If x is a variable of type ty and M is an abstraction (with bound variable y of type ty and body t), then $ALPHA_CONV \times M$ returns the theorem:

|-(y.t) = (x'.t[x'/y])

where the variable x':ty is a primed variant of x chosen so as not to be free in y.t.

Failure

ALPHA_CONV x tm fails if x is not a variable, if tm is not an abstraction, or if x is a variable v and tm is a lambda abstraction y.t but the types of v and y differ.

See also

ALPHA, GEN_ALPHA_CONV.

ancestry

ancestry : string -> string list

Synopsis

Gets a list of the (proper) ancestry of a theory.

Description

A call to ancestry "th" returns a list of all the proper ancestors (i.e. parents, parents of parents, etc.) of the theory th.

Failure

Fails if "th" is not an ancestor of the current theory.

See also

parents.

AND_EXISTS_CONV

AND_EXISTS_CONV : conv

Synopsis

Moves an existential quantification outwards through a conjunction.

Description

When applied to a term of the form $(?x.P) \land (?x.Q)$, where x is free in neither P nor Q, AND_EXISTS_CONV returns the theorem:

|-(?x. P) / (?x. Q) = (?x. P / Q)

Failure

AND_EXISTS_CONV fails if it is applied to a term not of the form (?x.P) / (?x.Q), or if it is applied to a term (?x.P) / (?x.Q) in which the variable x is free in either P or Q.

See also

EXISTS_AND_CONV, LEFT_AND_EXISTS_CONV, RIGHT_AND_EXISTS_CONV.

AND_FORALL_CONV

AND_FORALL_CONV : conv

Synopsis

Moves a universal quantification outwards through a conjunction.

Description

When applied to a term of the form (!x.P) / (!x.Q), the conversion AND_FORALL_CONV returns the theorem:

|-(!x.P) / (!x.Q) = (!x. P / Q)

Failure

Fails if applied to a term not of the form (!x.P) / (!x.Q).

See also

FORALL_AND_CONV, LEFT_AND_FORALL_CONV, RIGHT_AND_FORALL_CONV.

ANTE_CONJ_CONV

ANTE_CONJ_CONV : conv

Synopsis

Eliminates a conjunctive antecedent in favour of implication.

Description

When applied to a term of the form (t1 / t2) ==> t, the conversion ANTE_CONJ_CONV returns the theorem:

|-(t1 / t2 ==> t) = (t1 ==> t2 ==> t)

Failure

Fails if applied to a term not of the form "(t1 /\ t2) ==> t".

Uses

Somewhat ad-hoc, but can be used (with CONV_TAC) to transform a goal of the form $?-(P \land Q) ==> R$ into the subgoal ?-P ==> (Q ==> R), so that only the antecedent P is moved into the assumptions by DISCH_TAC.

ANTE_RES_THEN

ANTE_RES_THEN : thm_tactical

Synopsis

Resolves implicative assumptions with an antecedent.

Description

Given a theorem-tactic ttac and a theorem A |-t, the function ANTE_RES_THEN produces a tactic that attempts to match t to the antecedent of each implication

Ai |- !x1...xn. ui ==> vi

(where Ai is just !x1...xn. ui ==> vi) that occurs among the assumptions of a goal. If the antecedent ui of any implication matches t, then an instance of Ai u A |- vi is

obtained by specialization of the variables x1, ..., xn and type instantiation, followed by an application of modus ponens. Because all implicative assumptions are tried, this may result in several modus-ponens consequences of the supplied theorem and the assumptions. Tactics are produced using ttac from all these theorems, and these tactics are applied in sequence to the goal. That is,

```
ANTE_RES_THEN ttac (A |- t) g
```

has the effect of:

MAP_EVERY ttac [A1 u A |- v1; ...; Am u A |- vm] g

where the theorems Ai $u \land |-vi$ are all the consequences that can be drawn by a (single) matching modus-ponens inference from the implications that occur among the assumptions of the goal g and the supplied theorem $\land |-t$. Any negation $\sim v$ that appears among the assumptions of the goal is treated as an implication $v \implies F$. The sequence in which the theorems Ai $u \land |-vi$ are generated and the corresponding tactics applied is unspecified.

Failure

ANTE_RES_THEN ttac (A |-t) fails when applied to a goal g if any of the tactics produced by ttac (Ai u A |-vi), where Ai u A |-vi is the ith resolvent obtained from the theorem A |-t and the assumptions of g, fails when applied in sequence to g.

See also

```
IMP_RES_TAC, IMP_RES_THEN, MATCH_MP, RES_TAC, RES_THEN.
```

AP_TERM

 AP_TERM : (term -> thm -> thm)

Synopsis

Applies a function to both sides of an equational theorem.

Description

When applied to a term f and a theorem $A \mid -x = y$, the inference rule AP_TERM returns

the theorem A |-f x = f y. A |-x = y----- AP_TERM f A |-f x = f y

Failure

Fails unless the theorem is equational and the supplied term is a function whose domain type is the same as the type of both sides of the equation.

See also

AP_THM, MK_COMB.

AP_TERM_TAC

AP_TERM_TAC : tactic

Synopsis

Strips a function application from both sides of an equational goal.

Description

AP_TERM_TAC reduces a goal of the form A ?- f x = f y by stripping away the function applications, giving the new goal A ?- x = y.

A ?- f x = f y =========== AP_TERM_TAC A ?- x = y

Failure

Fails unless the goal is equational, with both sides being applications of the same function.

See also AP_TERM, AP_THM.

AP_THM

 AP_THM : (thm -> term -> thm)

Synopsis

Proves equality of equal functions applied to a term.

Description

When applied to a theorem $A \mid -f = g$ and a term x, the inference rule AP_THM returns the theorem $A \mid -f x = g x$.

 $\begin{array}{cccc} A & |-f = g \\ \hline & & \\ A & |-f x = g x \end{array}$

Failure

Fails unless the conclusion of the theorem is an equation, both sides of which are functions whose domain type is the same as that of the supplied term.

See also

AP_TERM, ETA_CONV, EXT, MK_COMB.

AP_THM_TAC

AP_THM_TAC : tactic

Synopsis

Strips identical operands from functions on both sides of an equation.

Description

When applied to a goal of the form A ?- f x = g x, the tactic AP_THM_TAC strips away the operands of the function application:

A ?- f x = g x ============= AP_THM_TAC A ?- f = g

Failure

Fails unless the goal has the above form, namely an equation both sides of which consist of function applications to the same arguments.

See also

AP_TERM, AP_TERM_TAC, AP_THM, EXT.

30

arity

arity : (string -> int)

Synopsis

Returns the arity of a type operator.

Description

arity "op" returns n if op is the name of an n-ary type operator (n can be 0), and otherwise fails.

Failure

arity st fails if st is not the name of a type constant or type operator.

See also

is_type.

ASM_CASES_TAC

ASM_CASES_TAC : (term -> tactic)

Synopsis

Given a term, produces a case split based on whether or not that term is true.

Description

Given a term u, ASM_CASES_TAC applied to a goal produces two subgoals, one with u as an assumption and one with \sim u:

A ?- t ======= ASM_CASES_TAC u A u {u} ?- t A u {~u} ?- t

ASM_CASES_TAC u is implemented by DISJ_CASES_TAC(SPEC u EXCLUDED_MIDDLE), where EXCLUDED_MIDDLE is the axiom $|- !u. u \rangle / ~u.$

Failure

By virtue of the implementation (see above), the decomposition fails if EXCLUDED_MIDDLE cannot be instantiated to u, e.g. if u does not have boolean type.

Example

The tactic ASM_CASES_TAC u can be used to produce a case analysis on u:

```
- let val u = Parse.Term 'u:bool'
    val g = Parse.Term '(P:bool -> bool) u'
in
ASM_CASES_TAC u ([],g)
end;
([([--'u'--], --'P u'--),
    ([--'~u'--], --'P u'--)], -) : tactic_result
```

Uses

Performing a case analysis according to whether a given term is true or false.

See also

BOOL_CASES_TAC, COND_CASES_TAC, DISJ_CASES_TAC, SPEC, STRUCT_CASES_TAC.

ASM_MESON_TAC

mesonLib.ASM_MESON_TAC : thm list -> tactic

Synopsis

Performs first order proof search to prove the goal, using the assumptions and the theorems given.

Description

ASM_MESON_TAC is identical in behaviour to MESON_TAC except that it uses the assumptions of a goal as well as the provided theorems.

Failure

ASM_MESON_TAC fails if it can not find a proof of the goal with depth less than or equal to the mesonLib.max_depth value.

See also

GEN_MESON_TAC, MESON_TAC

ASM_REWRITE_RULE

ASM_REWRITE_RULE : (thm list -> thm -> thm)

32

Synopsis

Rewrites a theorem including built-in rewrites and the theorem's assumptions.

Description

ASM_REWRITE_RULE rewrites with the tautologies in basic_rewrites, the given list of theorems, and the set of hypotheses of the theorem. All hypotheses are used. No ordering is specified among applicable rewrites. Matching subterms are searched for recursively, starting with the entire term of the conclusion and stopping when no rewritable expressions remain. For more details about the rewriting process, see GEN_REWRITE_RULE. To avoid using the set of basic tautologies, see PURE_ASM_REWRITE_RULE.

Failure

ASM_REWRITE_RULE does not fail, but may result in divergence. To prevent divergence where it would occur, ONCE_ASM_REWRITE_RULE can be used.

See also

GEN_REWRITE_RULE, ONCE_ASM_REWRITE_RULE, PURE_ASM_REWRITE_RULE, PURE_ONCE_ASM_REWRITE_RULE, REWRITE_RULE.

ASM_REWRITE_TAC

ASM_REWRITE_TAC : (thm list -> tactic)

Synopsis

Rewrites a goal including built-in rewrites and the goal's assumptions.

Description

ASM_REWRITE_TAC generates rewrites with the tautologies in basic_rewrites, the set of assumptions, and a list of theorems supplied by the user. These are applied top-down and recursively on the goal, until no more matches are found. The order in which the set of rewrite equations is applied is an implementation matter and the user should not depend on any ordering. Rewriting strategies are described in more detail under GEN_REWRITE_TAC. For omitting the common tautologies, see the tactic PURE_ASM_REWRITE_TAC. To rewrite with only a subset of the assumptions use FILTER_ASM_REWRITE_TAC.

Failure

ASM_REWRITE_TAC does not fail, but it can diverge in certain situations. For rewriting to a limited depth, see ONCE_ASM_REWRITE_TAC. The resulting tactic may not be valid if

the applicable replacement introduces new assumptions into the theorem eventually proved.

Example

The use of assumptions in rewriting, specially when they are not in an obvious equational form, is illustrated below:

```
- let val asm = [Parse.Term '(P:'a->bool) x']
    val goal = Parse.Term '(P:'a->bool) x = (Q:'a -> bool) x'
in
ASM_REWRITE_TAC[](asm, goal)
end;
val it = ([([--'P x'--], --'Q x'--)], fn) : tactic_result
- let val asm = [Parse.Term '~(P:'a->bool) x']
    val goal = Parse.Term '(P:'a->bool) x = (Q:'a -> bool) x'
in
ASM_REWRITE_TAC[](asm, goal)
end;
val it = ([([--'~P x'--], --'~Q x'--)], fn) : tactic_result
```

See also

basic_rewrites, FILTER_ASM_REWRITE_TAC, FILTER_ONCE_ASM_REWRITE_TAC, GEN_REWRITE_TAC, ONCE_ASM_REWRITE_TAC, ONCE_REWRITE_TAC, PURE_ASM_REWRITE_TAC, PURE_ONCE_ASM_REWRITE_TAC, PURE_REWRITE_TAC, REWRITE_TAC, SUBST_TAC.

ASM_SIMP_RULE

simpLib.ASM_SIMP_RULE : simpset -> thm list -> thm -> thm

Synopsis

Simplifies a theorem, using the theorem's assumptions as rewrites in addition to the provided rewrite theorems and simpset.

Failure

Never fails, but may diverge.

Example

```
- ASM_SIMP_RULE bool_ss [] (ASSUME (Term 'x = 3'))
> val it = [.] |- T : thm
```

Uses

Not clear to this author.

See also SIMP_CONV, SIMP_RULE.

ASM_SIMP_TAC

```
simpLib.ASM_SIMP_TAC : simpset -> thm list -> tactic
```

Synopsis

Simplifies a goal using the simpset, the provided theorems, and the goal's assumptions.

Description

ASM_SIMP_TAC does a simplification of the goal, adding both the assumptions and the provided theorem to the given simpset as rewrites. This simpset is then applied to the goal in the manner explained in the entry for SIMP_CONV.

ASM_SIMP_TAC is to SIMP_TAC, as ASM_REWRITE_TAC is to REWRITE_TAC.

Failure

ASM_SIMP_TAC never fails, though it may diverge.

Example

Here, hol_ss and the one assumption are used to demonstrate the proof of a simple arithmetic fact:

```
- ASM_SIMP_TAC hol_ss [] ([Term'x < y'], Term'x + y < y + y');
> val it = ([], fn) : tactic_result
```

See also

```
++, bool_ss, FULL_SIMP_TAC, hol_ss, mk_simpset, SIMP_CONV, SIMP_TAC.
```

assert

assert : ('a -> bool) -> 'a -> 'a

Synopsis

Checks that a value satisfies a predicate.

Description

assert p x returns x if the application p x yields true. Otherwise, assert p x fails.

Failure

assert p x fails with exception HOL_ERR if the predicate p yields false when applied to the value x.

Example

```
- null [];
> val it = true : bool
- assert null ([]:int list);
> val it = [] : int list
- null [1];
> false : bool
- assert null [1];
! Uncaught exception:
! HOL_ERR <poly>
```

See also

can.

assoc

Lib.assoc : ''a -> (''a * 'b) list -> ''a * 'b

Synopsis

Searches a list of pairs for a pair whose first component equals a specified value.

Description

assoc x [(x1,y1),...,(xn,yn)] returns the first (xi,yi) in the list such that xi equals x. The lookup is done on an eqtype, i.e., the SML implementation must be able to decide equality for the type of x.

Failure

Fails if no matching pair is found. This will always be the case if the list is empty.

Example

```
- assoc 2 [(1,4),(3,2),(2,5),(2,6)];
> val it = (2, 5) : (int * int)
```

See also

```
assoc1, assoc2, rev_assoc, find, mem, tryfind, exists, forall.
```

associate_restriction

```
associate_restriction : ((string * string) -> unit)
```

Synopsis

Associates a restriction semantics with a binder.

Description

If B is a binder and RES_B a constant then

```
associate_restriction("B", "RES_B")
```

will cause the parser and pretty-printer to support:

---- parse ----> Bv::P. B RES_B P (\v. B) <---- print ----

Anything can be written between the binder and '::' that could be written between the binder and '.' in the old notation. See the examples below.

Associations between user defined binders and their restrictions are not stored in the theory, so they have to be set up for each hol session (e.g. with a hol-init.ml file).

The flag '#restrict(Globals.pp_flags)' has default true, but if set to false will disable the pretty printing. This is useful for seeing what the semantics of particular restricted abstractions are. The following associations are predefined:

\v∷P. B	<>	RES_ABSTRACT	Ρ	(\v.	B)
!v::₽. B	<>	RES_FORALL	Ρ	(\v.	B)
?v::P. B	<>	RES_EXISTS	Ρ	(\v.	B)
@v::P. B	<>	RES_SELECT	Ρ	(\v.	B)

Where the constants RES_ABSTRACT, RES_FORALL, RES_EXISTS and RES_SELECT are defined in the theory 'restr_binder' by:

 $|- \text{RES}_\text{ABSTRACT P B} = \x: 'a. (P x \implies B x | ARB: 'b)$ $|- \text{RES}_\text{FORALL P B} = !x: 'a. P x \implies B x$ $|- \text{RES}_\text{EXISTS P B} = ?x: 'a. P x / \ B x$ $|- \text{RES}_\text{SELECT P B} = @x: 'a. P x / \ B x$

where ARB is defined in the theory 'restr_binder' by:

|-ARB = @x:'a.T

Failure

Never fails.

Example

```
- new_binder_definition("DURING", -- 'DURING(p:num#num->bool) = $!p'--);
  |-!p. $DURING p = $! p
- -- 'DURING x:: (m,n). p x'--;
 Exception raised at Parse_support.restr_binder:
  no restriction associated with "DURING"
- new_definition("RES_DURING",
                 --'RES_DURING(m,n)p = !x. m<=x /\ x<=n ==> p x'--);
  |- !m n p. RES_DURING (m,n) p = (!x. m <= x /\ x <= n ==> p x) : thm
- associate_restriction("DURING", "RES_DURING");
  () : unit
- -- 'DURING x::(m,n). p x'--;
  (--'DURING x ::(m,n). p x'--) : term
- Globals.show_restrict := false;
  () : unit
- -- 'DURING x:: (m,n). p x'--;
  (--'RES_DURING (m,n) (\x. p x)'--) : term
```

See also binder_restrictions, delete_restriction

ASSUME

ASSUME : (term -> thm)

Synopsis

Introduces an assumption.

Description

When applied to a term t, which must have type bool, the inference rule ASSUME returns

the theorem t |-t.

----- ASSUME t t |- t

Failure

Fails unless the term t has type bool.

Comments

The type of ASSUME is shown by the system as conv.

See also

ADD_ASSUM, REFL.

ASSUME_TAC

ASSUME_TAC : thm_tactic

Synopsis

Adds an assumption to a goal.

Description

Given a theorem th of the form A' |-u, and a goal, ASSUME_TAC th adds u to the assumptions of the goal.

A ?- t ============ ASSUME_TAC (A' |- u) A u {u} ?- t

Note that unless A' is a subset of A, this tactic is invalid.

Failure

Never fails.

Example

Given a goal g of the form $\{x = y, y = z\}$?- P, where x, y and z have type : 'a, the

theorem x = y, y = z | - x = z can, first, be inferred by forward proof

```
let val eq1 = Parse.Term '(x:'a) = y'
val eq2 = Parse.Term '(y:'a) = z'
in
TRANS (ASSUME eq1) (ASSUME eq2)
end;
```

and then added to the assumptions. This process requires the explicit text of the assumptions, as well as invocation of the rule ASSUME:

```
let val eq1 = Parse.Term '(x:'a) = y'
    val eq2 = Parse.Term '(y:'a) = z'
    val goal = ([eq1,eq2],Parse.Term 'P:bool')
in
ASSUME_TAC (TRANS (ASSUME eq1) (ASSUME eq2)) goal
end;
val it = ([([--'x = z'--, --'x = y'--, --'y = z'--], --'P'--)], fn)
    : tactic_result
```

This is the naive way of manipulating assumptions; there are more advanced proof styles (more elegant and less transparent) that achieve the same effect, but this is a perfectly correct technique in itself.

Alternatively, the axiom EQ_TRANS could be added to the assumptions of g:

A subsequent resolution (see RES_TAC) would then be able to add the assumption "x = z" to the subgoal shown above. (Aside from purposes of example, it would be more usual to use IMP_RES_TAC than ASSUME_TAC followed by RES_TAC in this context.)

Uses

ASSUME_TAC is the naive way of manipulating assumptions (i.e. without recourse to advanced tacticals); and it is useful for enriching the assumption list with lemmas as a prelude to resolution (RES_TAC, IMP_RES_TAC), rewriting with assumptions (ASM_REWRITE_TAC and so on), and other operations involving assumptions.

See also

ACCEPT_TAC, IMP_RES_TAC, RES_TAC, STRIP_ASSUME_TAC.

ASSUM_LIST

ASSUM_LIST : ((thm list -> tactic) -> tactic)

Synopsis

Applies a tactic generated from the goal's assumption list.

Description

When applied to a function of type thm list -> tactic and a goal, ASSUM_LIST constructs a tactic by applying f to a list of ASSUMEd assumptions of the goal, then applies that tactic to the goal.

ASSUM_LIST f ({A1;...;An} ?- t) = f [A1 |- A1; ...; An |- An] ({A1;...;An} ?- t)

Failure

Fails if the function fails when applied to the list of ASSUMEd assumptions, or if the resulting tactic fails when applied to the goal.

Comments

There is nothing magical about ASSUM_LIST: the same effect can usually be achieved just as conveniently by using ASSUME a wherever the assumption a is needed. If ASSUM_LIST is used, it is extremely unwise to use a function which selects elements from its argument list by number, since the ordering of assumptions should not be relied on.

Example

The tactic:

ASSUM_LIST SUBST_TAC

makes a single parallel substitution using all the assumptions, which can be useful if the rewriting tactics are too blunt for the required task.

Uses

Making more careful use of the assumption list than simply rewriting or using resolution.

See also

ASM_REWRITE_TAC, EVERY_ASSUM, IMP_RES_TAC, POP_ASSUM, POP_ASSUM_LIST, REWRITE_TAC.

axiom

axiom : (string -> string -> thm)

Synopsis

Loads an axiom from a given theory segment of the current theory.

Description

A call of axiom "thy" "ax" returns axiom ax from the theory segment thy. The theory segment thy must be part of the current theory. The name ax is the name given to the axiom by the user when it was originally added to the theory segment (by a call to new_axiom). The name of the current theory segment can be abbreviated by "-".

Failure

The call axiom "thy" "ax" will fail if the theory segment thy is not part of the current theory. It will also fail if there does not exist an axiom of name ax in theory segment thy.

Example

- axiom "bool" "BOOL_CASES_AX"; val it = |-!t. (t = T) \setminus / (t = F) : thm

See also

axioms, definition, new_axiom, print_theory, theorem.

axioms

axioms : (string -> (string # thm) list)

Synopsis

Returns the axioms of a given theory segment of the current theory.

Description

A call axioms "thy" returns the axioms of the theory segment thy together with their names. The theory segment thy must be part of the current theory. The names are those given to the axioms by the user when they were originally added to the theory segment (by a call to new_axiom). The name of the current theory segment can be abbreviated by "-".

Failure

The call axioms "thy" will fail if the theory segment thy is not part of the current theory.

Example

```
- axioms"bool";
val it =
 [("INFINITY_AX",|- ?f. ONE_ONE f /\ ~(ONTO f)),
 ("SELECT_AX",|- !P x. P x ==> P ($@ P)),
 ("ETA_AX",|- !t. (\x. t x) = t),
 ("IMP_ANTISYM_AX",|- !t1 t2. (t1 ==> t2) ==> (t2 ==> t1) ==> (t1 = t2)),
 ("BOOL_CASES_AX",|- !t. (t = T) \/ (t = F))] : (string * thm) list
```

See also

axiom, definitions, load_axiom, load_axioms, new_axiom, print_theory, theorems.

b

b : (void -> void)

Synopsis

Restores the proof state undoing the effects of a previous expansion.

Description

The function b is part of the subgoal package. It is an abbreviation for the function backup. For a description of the subgoal package, see set_goal.

Failure

As for backup.

44

Uses

Back tracking in a goal-directed proof to undo errors or try different tactics.

See also

backup, backup_limit, e, expand, expandf, g, get_state, p, print_state, r, rotate, save_top_thm, set_goal, set_state, top_goal, top_thm.

В

B : (('a -> 'b) -> ('c -> 'a) -> 'c -> 'b)

Synopsis Performs curried function-composition: B f g x = f (g x).

Comments Not yet in hol90

Failure Never fails.

See also ##, C, I, K, o, S, W.

backup

backup : (void -> void)

Synopsis

Restores the proof state, undoing the effects of a previous expansion.

Description

The function backup is part of the subgoal package. It allows backing up from the last state change (caused by calls to expand, set_goal, rotate and their abbreviations, or to set_state). The package maintains a backup list of previous proof states. A call to backup restores the state to the previous state (which was on top of the backup list). The current state and the state on top of the backup list are discarded. The maximum number of proof states saved on the backup list is one greater than the value of the

В

assignable variable backup_limit. This variable is initially set to 12. Adding new proof states after the maximum is reached causes the earliest proof state on the list to be discarded. The user may backup repeatedly until the list is exhausted. The state restored includes all unproven subgoals or, if a goal had been proved in the previous state, the corresponding theorem. backup is abbreviated by the function b. For a description of the subgoal package, see set_goal.

Failure

The function backup will fail if the backup list is empty.

Example

```
#g "(HD[1;2;3] = 1) /\ (TL[1;2;3] = [2;3])";;
"(HD[1;2;3] = 1) / (TL[1;2;3] = [2;3])"
() : void
#e CONJ_TAC;;
OK..
2 subgoals
"TL[1;2;3] = [2;3]"
"HD[1;2;3] = 1"
() : void
#backup();;
"(HD[1;2;3] = 1) /\ (TL[1;2;3] = [2;3])"
() : void
#e (REWRITE_TAC[HD;TL]);;
OK..
goal proved
|-(HD[1;2;3] = 1) / (TL[1;2;3] = [2;3])
Previous subproof:
goal proved
() : void
```

Uses

Back tracking in a goal-directed proof to undo errors or try different tactics.

See also

```
b, backup_limit, e, expand, expandf, g, get_state, p, print_state, r, rotate,
save_top_thm, set_goal, set_state, top_goal, top_thm.
```

BETA_CONV

BETA_CONV : conv

Synopsis

Performs a simple beta-conversion.

Description

The conversion BETA_CONV maps a beta-redex "(\x.u)v" to the theorem

|-(x.u)v = u[v/x]

where u[v/x] denotes the result of substituting v for all free occurrences of x in u, after renaming sufficient bound variables to avoid variable capture. This conversion is one of the primitive inference rules of the HOL system.

Failure

BETA_CONV tm fails if tm is not a beta-redex.

Example

```
- let val tm = Parse.Term '(\x.x+1)y'
in
BETA_CONV tm
end;
val it = |- (\x. x + 1)y = y + 1 :thm
- let val tm = Parse.Term '(\x y. x+y)y'
in
BETA_CONV tm
end;
val it = |- (\x y. x + y)y = (\y'. y + y') : thm
```

Comments

This primitive inference rule is actually not very primitive, since it does automatic bound variable renaming. It would be logically cleaner for this renaming to be derived rather than built-in, but since beta-reduction is so common this would slow the system down a lot. It is hoped to document the exact renaming algorithm used by BETA_CONV in the future.

See also

```
BETA_RULE, BETA_TAC, LIST_BETA_CONV, PAIRED_BETA_CONV, RIGHT_BETA, RIGHT_LIST_BETA.
```

BETA_RULE

BETA_RULE : (thm -> thm)

Synopsis

Beta-reduces all the beta-redexes in the conclusion of a theorem.

Description

When applied to a theorem $A \mid -t$, the inference rule BETA_RULE beta-reduces all beta-redexes, at any depth, in the conclusion t. Variables are renamed where necessary to avoid free variable capture.

A |-((\x. s1) s2).... ------ BETA_RULE A |-(s1[s2/x])....

Failure

Never fails, but will have no effect if there are no beta-redexes.

Example

The following example is a simple reduction which illustrates variable renaming:

```
- Globals.show_assums := true;
val it = () : unit
- local val tm = Parse.Term 'f = ((\x y. x + y) y)'
in
val x = ASSUME tm
end;
val x = [f = (\x y. x + y)y] |- f = (\x y. x + y)y : thm
- BETA_RULE x;
val it = [f = (\x y. x + y)y] |- f = (\y'. y + y') : thm
```

See also

BETA_CONV, BETA_TAC, PAIRED_BETA_CONV, RIGHT_BETA.

BETA_TAC

BETA_TAC : tactic

Synopsis

Beta-reduces all the beta-redexes in the conclusion of a goal.

Description

When applied to a goal A ?- t, the tactic BETA_TAC produces a new goal which results from beta-reducing all beta-redexes, at any depth, in t. Variables are renamed where necessary to avoid free variable capture.

Failure

Never fails, but will have no effect if there are no beta-redexes.

See also

BETA_CONV, BETA_TAC, PAIRED_BETA_CONV.

binders

```
binders : (string -> term list)
```

Synopsis

Lists the binders in the named theory.

Description

The function binders should be applied to a string which is the name of an ancestor theory (including the current theory; the special string "-" is always interpreted as the current theory). It returns a list of all the binders declared in the named theory.

Failure

Fails unless the given theory is an ancestor of the current theory.

Example

```
- binders "bool";
val it = ['$?!', '$!', '$@'] : term list
- binders "prod";
val it = [] : term list
```

See also

ancestors, axioms, constants, definitions, infixes, new_binder, parents, types.

binder_restrictions

binder_restrictions : unit -> (string * string) list

Synopsis

Shows the list of binder restrictions currently in force.

Description

associate_restriction is used to control the parsing and prettyprinting of restricted binders, which give the illusion of dependent types. The list of current restrictions is found by calling binder_restrictions. There are always at least the following restricted binders: ["!","?","@","

"].

Failure

Never fails.

Example

```
associate_restriction("DURING","RES_DURING");
() : unit
binder_restrictions();
[("DURING","RES_DURING"),("!","RES_FORALL"),("?","RES_EXISTS"),
```

```
("@","RES_SELECT"),("\\","RES_ABSTRACT")] : (string * string) list
```

See also

associate_restrictions, delete_restriction

BINOP_CONV

BINOP_CONV : conv -> conv

Synopsis

Applies a conversion to both arguments of a binary operator.

Description

If c is a conversion that when applied to t1 returns the theorem |-t1 = t1' and when applied to t2 returns the theorem |-t2 = t2', then BINOP_CONV c (Term'f t1 t2') will return the theorem

|-f t1 t2 = f t1' t2'

Failure

BINOP_CONV c t will fail if t is not of the general form f t1 t2, or if c fails when applied to either t1 or t2, or if c fails to return theorems of the form |-t1 = t1' and |-t2 = t2' when applied to those arguments. (The latter case would imply that c wasn't a conversion at all.)

Example

- BINOP_CONV REDUCE_CONV (Term'3 * 4 + 6 * 7'); > val it = |- 3 * 4 + 6 * 7 = 12 + 42 : Thm.thm

See also

FORK_CONV, LAND_CONV, RAND_CONV, RATOR_CONV

body

body : (term -> term)

Synopsis Returns the body of an abstraction.

Description

body '\v. t' returns 't'.

Failure

Fails unless the term is an abstraction.

See also bvar, dest_abs.

BODY_CONJUNCTS

```
BODY_CONJUNCTS : (thm -> thm list)
```

Synopsis

Splits up conjuncts recursively, stripping away universal quantifiers.

Description

When applied to a theorem, BODY_CONJUNCTS recursively strips off universal quantifiers by specialization, and breaks conjunctions into a list of conjuncts.

A |- !x1...xn. t1 /\ (!y1...ym. t2 /\ t3) /\ ... [A |- t1, A |- t2, A |- t3, ...]

Failure

Never fails, but has no effect if there are no top-level universal quantifiers or conjuncts.

Example

The following illustrates how a typical term will be split:

See also

CONJ, CONJUNCT1, CONJUNCT2, CONJUNCTS, CONJ_TAC.

bool

Type.bool : hol_type

Synopsis

Holds the logical type constant bool.

BOOL_CASES_TAC

```
BOOL_CASES_TAC : (term -> tactic)
```

Synopsis

Performs boolean case analysis on a (free) term in the goal.

Description

When applied to a term x (which must be of type bool but need not be simply a variable), and a goal A ?- t, the tactic BOOL_CASES_TAC generates the two subgoals corresponding to A ?- t but with any free instances of x replaced by F and T respectively.

A ?- t ======= BOOL_CASES_TAC "x" A ?- t[F/x] A ?- t[T/x]

The term given does not have to be free in the goal, but if it isn't, BOOL_CASES_TAC will merely duplicate the original goal twice.

Failure

Fails unless the term x has type bool.

Example

The goal:

?- (b ==> ~b) ==> (b ==> a)

can be completely solved by using BOOL_CASES_TAC on the variable b, then simply rewriting the two subgoals using only the inbuilt tautologies, i.e. by applying the following tactic:

BOOL_CASES_TAC (Parse.Term 'b:bool') THEN REWRITE_TAC[]

Uses

Avoiding fiddly logical proofs by brute-force case analysis, possibly only over a key term as in the above example, possibly over all free boolean variables.

See also

ASM_CASES_TAC, COND_CASES_TAC, DISJ_CASES_TAC, STRUCT_CASES_TAC.

bool_EQ_CONV

bool_EQ_CONV : conv

Synopsis

Simplifies expressions involving boolean equality.

Description

The conversion bool_EQ_CONV simplifies equations of the form t1 = t2, where t1 and t2 are of type bool. When applied to a term of the form t = t, the conversion bool_EQ_CONV returns the theorem

|-(t = t) = T

When applied to a term of the form t = T, the conversion returns

|-(t = T) = t

And when applied to a term of the form T = t, it returns

|-(T = t) = t

Failure

Fails unless applied to a term of the form t1 = t2, where t1 and t2 are boolean, and either t1 and t2 are syntactically identical terms or one of t1 and t2 is the constant T.

Example

```
- bool_EQ_CONV (Parse.Term 'T = F');
val it = |- (T = F) = F : thm
- bool_EQ_CONV (Parse.Term '(0 < n) = T');
val it = |- (0 < n = T) = 0 < n : thm</pre>
```

bool_rewrites

bool_rewrites: unit -> rewrites

Synopsis

Contains a number of built-in tautologies used, by default, in rewriting.

Description

The variable bool_rewrites represents a kind of database of rewrite rules commonly used to simplify expressions. These rules include the clause for reflexivity:

|-!x.(x = x) = T

as well as rules to reason about equality:

$$|-!t.$$

((T = t) = t) /\ ((t = T) = t) /\ ((F = t) = ~t) /\ ((t = F) = ~t)

Negations are manipulated by the following clauses:

|-(!t.~~t = t) / (~T = F) / (~F = T)

The set of tautologies includes truth tables for conjunctions, disjunctions, and implications:

```
|- !t.
     (T / \ t = t) / 
     (t / T = t) / 
     (F / \ t = F) / 
     (t /\ F = F) /\
     (t / \ t = t)
|- !t.
     (T \setminus / t = T) / 
     (t \backslash/ T = T) /\backslash
     (F \setminus / t = t) / 
     (t \backslash/ F = t) /\backslash
     (t \setminus / t = t)
|- !t.
     (T \implies t = t) / 
     (t ==> T = T) / 
     (F \implies t = T) / 
     (t ==> t = T) / 
     (t \implies F = \tilde{t})
```

Simple rules for reasoning about conditionals are given by:

|- !t1 t2. ((T => t1 | t2) = t1) /\ ((F => t1 | t2) = t2)

Rewriting with the following tautologies allows simplification of universally and exis-

tentially quantified variables and abstractions:

|- !t. (!x. t) = t
|- !t. (?x. t) = t
|- !t1 t2. (\x. t1)t2 = t1

Uses

The bool_rewrites are automatically included in the simplifications performed by some of the rewriting tools.

The bool_rewrites used to include rules for reasoning about pairs in HOL:

|- !x. FST x,SND x = x
|- !x y. FST(x,y) = x
|- !x y. SND(x,y) = y

However, because of recent changes in the system, the theory of pairs need not be loaded at the same time as the "bool" theory, so the above rewrites can be accessed through pairTheory.pair_rws.

bool_ss

boolSimps.bool_ss : simpset

Synopsis

Basic simpset containing standard propositional calculus rewrites, beta conversion, and eta conversion.

Description

The bool_ss simpset is almost at the base of the system-provided simpset hierarchy. Though not very powerful, it does include rewrite rules such as |-T / P = P, conversions to perform eta and beta reduction, and congruence rules to let simplification get additional contextual information as it descends through implications and congruences.

Failure

Can't fail, as it is not a functional value.

butlast

Uses

The bool_ss simpset is an appropriate simpset to use at the base of new user-defined simpsets, and is also useful in its own right where a delicate simplification is desired, where other more powerful simpsets might cause undue disruption to a goal. If even less system rewriting is desired, the pure_ss value can be used.

See also

```
hol_ss, pure_ss, SIMP_CONV, SIMP_TAC.
```

butlast

butlast : (* list -> * list)

Synopsis

Computes the sub-list of a list consisting of all but the last element.

Description

butlast [x1;...;xn] returns [x1;...;x(n-1)].

Failure

Fails if the list is empty.

See also

last, hd, tl, el, null.

bvar

bvar : (term -> term)

Synopsis

Returns the bound variable of an abstraction.

Description

bvar '\v. t' returns 'v'.

Failure

Fails unless the term is an abstraction.

See also

body, dest_abs.

С

C : ('a -> 'b -> 'c) -> 'b -> 'a -> 'c

Synopsis

Permutes first two arguments to curried function: C f x y = f y x.

Failure

Never fails.

See also

##, B, I, K, o, S, W.

can

can : ((* -> **) -> * -> bool)

Synopsis

Tests for failure.

Description

can f x evaluates to true if the application of f to x succeeds. It evaluates to false if the application fails.

Failure

Never fails.

Example

#hd [];;
evaluation failed hd

#can hd [];;
false : bool

See also

assert.

Cases

bossLib.Cases : tactic

Synopsis

Performs case analysis on the variable of a universally quantified goal.

Description

When applied to a universally quantified goal, Cases performs a case-split, based on the cases theorem for the type of the universally quantified variable stored in the global TypeBase database.

The cases theorem for a type ty will be of the form:

where there is no requirement for there to be more than one disjunct, nor for there to be any particular number of existentially quantified variables in any disjunct. For example, the cases theorem for natural numbers initially in the TypeBase is:

 $|-!n. (n = 0) \setminus / (?m. n = SUC m)$

Case-splitting consists of specialising the cases theorem with the variable from the goal and then generating as many sub-goals as there are disjuncts in the cases theorem, where in each sub-goal (including the assumptions) the variable has been replaced by an expression involving the given "constructor" (the Ci's above) applied to as many fresh variables as appropriate.

Failure

Fails if the goal is not universally quantified, or if the type of the universally quantified variable does not have a case theorem in the TypeBase, as will happen, for example, with variable types.

Example

If we have defined the following type:

- Hol_datatype 'foo = Bar of num | Baz of bool'; > val it = () : unit

and the following function:

then it is possible to make progress with the goal $!x. foofn x \ge 10$ by applying the tactic Cases, thus:

?- !x. foofn x >= 10
================================== Cases
?- foofn (Bar n) >= 10 ?- foofn (Baz b) >= 10

producing two new goals, one for each constructor of the type.

See also

Cases_on, Induct, STRUCT_CASES_TAC

CASES_THENL

CASES_THENL : (thm_tactic list -> thm_tactic)

Synopsis

Applies the theorem-tactics in a list to corresponding disjuncts in a theorem.

Description

When given a list of theorem-tactics [ttac1;...;ttacn] and a theorem whose conclusion is a top-level disjunction of n terms, CASES_THENL splits a goal into n subgoals resulting from applying to the original goal the result of applying the i'th theorem-tactic to the i'th disjunct. This can be represented as follows, where the number of existentially quantified variables in a disjunct may be zero. If the theorem th has the form:

A' |- ?x11..x1m. t1 \/ ... \/ ?xn1..xnp. tn

where the number of existential quantifiers may be zero, and for all i from 1 to n:

where the primed variables have the same type as their unprimed counterparts, then:

A ?- s ================= CASES_THENL [ttac1;...;ttacn] th A1 ?- s1 ... An ?- sn

Unless A' is a subset of A, this is an invalid tactic.

Failure

Fails if the given theorem does not, at the top level, have the same number of (possibly multiply existentially quantified) disjuncts as the length of the theorem-tactic list (this includes the case where the theorem-tactic list is empty), or if any of the tactics generated as specified above fail when applied to the goal.

Uses

Performing very general disjunctive case splits.

See also

DISJ_CASES_THENL, X_CASES_THENL.

CBV_CONV

CBV_CONV : comp_rws -> conv

Synopsis

Call by value rewriting.

Description

The conversion CBV_CONV expects an simplification set and a term. Its term argument is rewritten using the equations added in the simplification set. The strategy used is

somewhat similar to MI's, that is call-by-value (arguments of constants are completely reduced before the rewrites associated to the constant are applied) with weak reduction (no reduction of the function body before the function is applied). The main differences are that beta-redexes are reduced with a call-by-name strategy (the argument is not reduced), and reduction under binders is done when it occurs in a position where it cannot be substituted.

The simplification sets are mutable objects, this means they are extended by sideeffect. The function new_rws will create a new set containing only reflexivity (REFL_CLAUSE). Theorems can be added to a set with the function add_thms. The function from_list simply combines new_rws and add_thms.

It is also possible to add conversions to a simplification set with add_conv. The only restriction is that a constant (c) and an arity (n) must be provided. The conversion will be called only on terms in which c is applied to n arguments.

Two theorem "preprocessors" are provided to control the strictness of the arguments of a constant. lazyfy_thm has pattern variables on the left hand side turned into abstractions on the right hand side. This transformation is applied on every conjunct, and removes prenex universal quantifications. A typical example is COND_CLAUSES:

(COND T a b = a) / (COND F a b = b)

Using these equations is very inefficient because both a and b are evaluated, regardless of the value of the boolean expression. It is better to use COND_CLAUSES with the form above

(COND T = a b. a) /\ (COND F = a b. b)

The call-by-name evaluation of beta redexes avoids computing the unused branch of the conditional.

Conversely, strictify_thm does the reverse transformation. This is particularly relevant for LET_DEF:

LET = $f x. f x \longrightarrow LET f x = f x$

This forces the evaluation of the argument before reducing the beta-redex. Hence the usual behaviour of LET.

It is necessary to provide rules for all the constants appearing in the expression to reduce (all also for those that appear in the right hand side of a rule), unless the given constant is considered as a constructor of the representation chosen. As an example, initial_rws provides a way to create a new simplification set with all the rules needed for basic boolean and arithmetical calculations built in.

Example

Failing to give enough rules may make CBV_CONV build a huge result, or even loop. The same may occur if the initial term to reduce contains free variables.

```
val eqn = bossLib.Define 'exp n p = if p=0 then 1 else n * (exp n (p-1))';
val rws = bossLib.initial_rws();
val _ = add_thms(true,[eqn]) rws;
- CBV_CONV rws (--'exp 2 n'--);
> Interrupted.
- set_skip rws "COND" (SOME 1);
> val it = () : unit
- CBV_CONV rws (--'exp 2 n'--);
> val it = |- exp 2 n = (if n = 0 then 1 else 2 * exp 2 (n - 1)) : Thm.thm
```

The first invocation of CBV_CONV loops since the exponent never reduces to 0. Below the first steps are computed:

```
exp 2 n
if n = 0 then 1 else 2 * exp 2 (n-1)
if n = 0 then 1 else 2 * if (n-1) = 0 then 1 else 2 * exp 2 (n-1-1)
...
```

The call to set_skip means that if the constants COND appears applied to one argument and does not create a redex (in the example, if the condition does not reduce to T or F), then the forthcoming arguments (the two branches of the conditional) are not reduced at all.

Failure

Should never fail. Nonetheless, using rewrites with assumptions may cause problems

when rewriting under abstractions. The following example illustrates that issue.

- val th = ASSUME(--'0=x'--); - val tm = --'\(x:num).x=0'--; - val rws = from_list [th]; - CBV_CONV rws tm;

This fails because the 0 is replaced by x, making the assumption 0=x. Then, the abstraction cannot be rebuilt since x appears free in the assumptions.

See also

REDUCE_CONV, reduce_rws, initial_rws

CCONTR

CCONTR : (term -> thm -> thm)

Synopsis

Implements the classical contradiction rule.

Description

When applied to a term t and a theorem A \mid - F, the inference rule CCONTR returns the theorem A - {~t} \mid - t.

A |- F ----- CCONTR "t" A - {~t} |- t

Failure

Fails unless the term has type bool and the theorem has F as its conclusion.

Comments

The usual use will be when \tilde{t} exists in the assumption list; in this case, CCONTR corresponds to the classical contradiction rule: if \tilde{t} leads to a contradiction, then t must be true.

See also

CONTR, CONTRAPOS, CONTR_TAC, NOT_ELIM.

CCONTR_TAC

CCONTR_TAC : tactic

Synopsis

Prepares for a proof by Classical contradiction.

Description

CCONTR_TAC takes a theorem $A^{,} \mid -F$ and completely solves the goal. This is an invalid tactic unless $A^{,}$ is a subset of A.

A ?- t ====== CCONTR_TAC (A' |- F)

Failure

Fails unless the theorem is contradictory, i.e. has F as its conclusion.

See also

CHECK_ASSUME_TAC, CCONTR, CCCONTR, CONTRAPOS, NOT_ELIM.

CHANGED_CONV

CHANGED_CONV : (conv -> conv)

Synopsis

Makes a conversion fail if applying it leaves a term unchanged.

Description

If c is a conversion that maps a term "t" to a theorem |-t = t', where t' is alphaequivalent to t, then CHANGED_CONV c is a conversion that fails when applied to the term "t". If c maps "t" to |-t = t', where t' is not alpha-equivalent to t, then CHANGED_CONV c also maps "t" to |-t = t'. That is, CHANGED_CONV c is the conversion that behaves exactly like c, except that it fails whenever the conversion c would leave its input term unchanged (up to alpha-equivalence).

Failure

CHANGED_CONV c "t" fails if c maps "t" to |-t = t', where t' is alpha-equivalent to t, or if c fails when applied to "t". The function returned by CHANGED_CONV c may also fail if the ML function c:term->thm is not, in fact, a conversion (i.e. a function that maps a term t to a theorem |-t = t').

Uses

CHANGED_CONV is used to transform a conversion that may leave terms unchanged, and therefore may cause a nonterminating computation if repeated, into one that can safely be repeated until application of it fails to substantially modify its input term.

CHANGED_TAC

CHANGED_TAC : (tactic -> tactic)

Synopsis

Makes a tactic fail if it has no effect.

Description

When applied to a tactic T, the tactical CHANGED_TAC gives a new tactic which is the same as T if that has any effect, and otherwise fails.

Failure

The application of CHANGED_TAC to a tactic never fails. The resulting tactic fails if the basic tactic either fails or has no effect.

See also

TRY, VALID.

CHECK_ASSUME_TAC

CHECK_ASSUME_TAC : thm_tactic

Synopsis

Adds a theorem to the assumption list of goal, unless it solves the goal.

66

Description

When applied to a theorem A' |-s and a goal A ?- t, the tactic CHECK_ASSUME_TAC checks whether the theorem will solve the goal (this includes the possibility that the theorem is just A' |-F). If so, the goal is duly solved. If not, the theorem is added to the assumptions of the goal, unless it is already there.

```
A ?- t

================= CHECK_ASSUME_TAC (A' |- F) [special case 1]

A ?- t

================ CHECK_ASSUME_TAC (A' |- t) [special case 2]

A ?- t

==================== CHECK_ASSUME_TAC (A' |- s) [general case]

A u {s} ?- t
```

Unless A' is a subset of A, the tactic will be invalid, although it will not fail.

Failure

Never fails.

See also

ACCEPT_TAC, ASSUME_TAC, CONTR_TAC, DISCARD_TAC, MATCH_ACCEPT_TAC.

CHOOSE

CHOOSE : ((term # thm) \rightarrow thm \rightarrow thm)

Synopsis

Eliminates existential quantification using deduction from a particular witness.

Description

When applied to a term-theorem pair (v, A1 | - ?x. s) and a second theorem of the form A2 u {s[v/x]} |- t, the inference rule CHOOSE produces the theorem A1 u A2 |- t.

A1 |- ?x. s A2 u {s[v/x]} |- t ----- CHOOSE ("v",(A1 |- ?x. s)) A1 u A2 |- t

Where v is not free in A1, A2 or t.

Failure

Fails unless the terms and theorems correspond as indicated above; in particular v must have the same type as the variable existentially quantified over, and must not be free in A1, A2 or t.

See also

CHOOSE_TAC, EXISTS, EXISTS_TAC, SELECT_ELIM.

CHOOSE_TAC

CHOOSE_TAC : thm_tactic

Synopsis

Adds the body of an existentially quantified theorem to the assumptions of a goal.

Description

When applied to a theorem A' \mid - ?x. t and a goal, CHOOSE_TAC adds t[x'/x] to the assumptions of the goal, where x' is a variant of x which is not free in the assumption list; normally x' is just x.

```
A ?- u
============ CHOOSE_TAC (A' |- ?x. t)
A u {t[x'/x]} ?- u
```

Unless A' is a subset of A, this is not a valid tactic.

Failure

Fails unless the given theorem is existentially quantified.

Example

Suppose we have a goal asserting that the output of an electrical circuit (represented as

68

a boolean-valued function) will become high at some time:

?- ?t. output(t)

and we have the following theorems available:

t1 = |- ?t. input(t)
t2 = !t. input(t) ==> output(t+1)

Then the goal can be solved by the application of:

CHOOSE_TAC t1 THEN EXISTS_TAC "t+1" THEN UNDISCH_TAC "input (t:num) :bool" THEN MATCH_ACCEPT_TAC t2

See also

CHOOSE_THEN, X_CHOOSE_TAC.

CHOOSE_THEN

CHOOSE_THEN : thm_tactical

Synopsis

Applies a tactic generated from the body of existentially quantified theorem.

Description

When applied to a theorem-tactic ttac, an existentially quantified theorem A' |-?x.t, and a goal, CHOOSE_THEN applies the tactic ttac (t[x'/x] |-t[x'/x])) to the goal, where x' is a variant of x chosen not to be free in the assumption list of the goal. Thus if:

```
A ?- s1
======== ttac (t[x'/x] |- t[x'/x])
B ?- s2
```

then

```
A ?- s1
======= CHOOSE_THEN ttac (A' |- ?x. t)
B ?- s2
```

This is invalid unless A' is a subset of A.

Failure

Fails unless the given theorem is existentially quantified, or if the resulting tactic fails when applied to the goal.

Example

This theorem-tactical and its relatives are very useful for using existentially quantified theorems. For example one might use the inbuilt theorem

LESS_ADD_1 = |- !m n. n < m ==> (?p. m = n + (p + 1))

to help solve the goal

?-x < y ==> 0 < y * y

by starting with the following tactic

DISCH_THEN (CHOOSE_THEN SUBST1_TAC o MATCH_MP LESS_ADD_1)

which reduces the goal to

?-0 < ((x + (p + 1)) * (x + (p + 1)))

which can then be finished off quite easily, by, for example:

REWRITE_TAC[ADD_ASSOC, SYM (SPEC_ALL ADD1), MULT_CLAUSES, ADD_CLAUSES, LESS_0]

See also

CHOOSE_TAC, X_CHOOSE_THEN.

clear_overloads_on

Parse.clear_overloads_on : string -> unit

Synopsis

Clears all overloading on the specified operator.

Description

This function removes all overloading associated with the given string.

Failure

Never fails. If a string is not overloaded, this function simply has no effect.

Example

```
- load "realTheory";
> val it = () : unit
- realTheory.REAL_INV_LT1;
> val it = |- !x. 0 < x /\ x < 1 ==> 1 < inv x : Thm.thm
- clear_overloads_on "<";
> val it = () : unit
- realTheory.REAL_INV_LT1;
> val it = |- !x. 0 real_lt x /\ x real_lt 1 ==> 1 real_lt inv x : Thm.thm
- clear_overloads_on "&";
> val it = () : unit
- realTheory.REAL_INV_LT1;
> val it = |- !x. 0r real_lt x /\ x real_lt 1r ==> 1r real_lt inv x : Thm.thm
```

Uses

If overloading gets too confusing, this function should help to clear away one layer of supposedly helpful obfuscation.

See also

overload_on.

clear_prefs_for_term

Parse.clear_prefs_for_term : string -> unit

Synopsis

Removes pretty-printing preference information from the global grammar.

Description

The clear_prefs_for_term function removes the information stored in the global grammar as to which (if any) rule should be preferred when terms are pretty-printed. This will cause terms of the given name to be printed using "raw" syntax.

Failure

Never fails.

Example

The initial grammar has two rules for conditional expressions, with the if-then-else form preferred, so that even if the old HOL88 style syntax is used for input, the term is

printed out in the if-then-else style:

```
- Term'p => q | r';
<<HOL message: inventing new type variable names: 'a.>>
> val it = '(if p then q else r)' : Term.term
```

If clear_prefs_for_term is applied, neither syntax will print:

```
- clear_prefs_for_term "COND";
> val it = () : unit
- Term'p => q | r';
<<HOL message: inventing new type variable names: 'a.>>
> val it = 'COND p q r' : Term.term
```

See also

prefer_form_with_tok

combine

```
combine : 'a list * 'b list -> ('a * 'b) list)
```

Synopsis

Converts a pair of lists into a list of pairs.

Description

combine ([x1,...,xn],[y1,...,yn]) returns [(x1,y1),...,(xn,yn)].

Failure

Fails if the two lists are of different lengths.

Comments

Has much the same effect as the SML Basis function ListPair.zip except that it fails if the arguments are not of equal length.

See also

split.

concat

concl

Synopsis

Concatenates two ML strings.

Failure

Never fails.

Example

```
- concat "1" "";
> val it = "1" : string
- concat "hello" "world";
> val it = "helloworld" : string
- concat "hello" (concat " " "world");
> val it = "hello world" : string
```

Comments

This function is open at the top level and is not the same as the Basis function String.concat. The latter concatenates a list of strings, replacing concatl in the HOL distribution.

concl

concl : (thm -> term)

Synopsis

Returns the conclusion of a theorem.

Description

When applied to a theorem A \mid - t, the function concl returns t.

Failure

Never fails.

See also dest_thm, hyp.

COND_CASES_TAC

COND_CASES_TAC : tactic

Synopsis

Induces a case split on a conditional expression in the goal.

Description

COND_CASES_TAC searches for a conditional sub-term in the term of a goal, i.e. a sub-term of the form p=>u|v, choosing one by its own criteria if there is more than one. It then induces a case split over p as follows:

where p is not a constant, and the term p=>u|v is free in t. Note that it both enriches the assumptions and inserts the assumed value into the conditional.

Failure

COND_CASES_TAC fails if there is no conditional sub-term as described above.

Example

For "x", "y", "z1" and "z2" of type ":*", and "P:*->bool",

COND_CASES_TAC ([], "x = (P y => z1 | z2)");; ([(["P y"], "x = z1"); (["~P y"], "x = z2")], -) : subgoals

but it fails, for example, if "y" is not free in the term part of the goal:

COND_CASES_TAC ([], "!y. x = (P y => z1 | z2)");; evaluation failed COND_CASES_TAC

In contrast, ASM_CASES_TAC does not perform the replacement:

```
ASM_CASES_TAC "P y" ([], "x = (P y => z1 | z2)");;
([(["P y"], "x = (P y => z1 | z2)"); (["~P y"], "x = (P y => z1 | z2)")],
-)
: subgoals
```

Uses

Useful for case analysis and replacement in one step, when there is a conditional subterm in the term part of the goal. When there is more than one such sub-term and one in particular is to be analyzed, COND_CASES_TAC cannot be depended on to choose the 'desired' one. It can, however, be used repeatedly to analyze all conditional sub-terms of a goal.

See also

ASM_CASES_TAC, DISJ_CASES_TAC, STRUCT_CASES_TAC.

74

COND_CONV

COND_CONV : conv

Synopsis

Simplifies conditional terms.

Description

The conversion COND_CONV simplifies a conditional term "c => u | v" if the condition c is either the constant T or the constant F or if the two terms u and v are equivalent up to alpha-conversion. The theorems returned in these three cases have the forms:

 $|-(T \Rightarrow u | v) = u$ $|-(F \Rightarrow u | v) = u$ $|-(c \Rightarrow u | u) = u$

Failure

COND_CONV tm fails if tm is not a conditional "c => u | v", where c is T or F, or u and v are alpha-equivalent.

CONJ

CONJ : (thm -> thm -> thm)

Synopsis

Introduces a conjunction.

Description

A1 |- t1 A2 |- t2 ----- CONJ A1 u A2 |- t1 /\ t2

Failure

Never fails.

See also

BODY_CONJUNCTS, CONJUNCT1, CONJUNCT2, CONJ_PAIR, LIST_CONJ, CONJ_LIST, CONJUNCTS.

CONJUNCT1

CONJUNCT1 : (thm -> thm)

Synopsis

Extracts left conjunct of theorem.

Description

A |- t1 /\ t2 ----- CONJUNCT1 A |- t1

Failure

Fails unless the input theorem is a conjunction.

See also

BODY_CONJUNCTS, CONJUNCT2, CONJ_PAIR, CONJ, LIST_CONJ, CONJ_LIST, CONJUNCTS.

CONJUNCT2

CONJUNCT2 : (thm -> thm)

Synopsis

Extracts right conjunct of theorem.

Description

A |- t1 /\ t2 ----- CONJUNCT2 A |- t2

Failure

Fails unless the input theorem is a conjunction.

See also

BODY_CONJUNCTS, CONJUNCT1, CONJ_PAIR, CONJ, LIST_CONJ, CONJ_LIST, CONJUNCTS.

conjuncts

hol88Lib.conjuncts : term -> term list

Synopsis

Iteratively splits conjunctions into a list of conjuncts.

Description

Found in the hol88 library. conjuncts $(--'t1 / \dots / tn'-)$ returns $[t1, \dots, tn]$. The argument term may be any tree of conjunctions. It need not have the form

--'t1 /\ (t2 /\ (... /\ tn)...)'--

A term that is not a conjunction is simply returned as the sole element of a list. Note that

```
conjuncts(list_mk_conj([t1,...,tn]))
```

will not return [t1,...,tn] if any of t1,...,tn are conjunctions.

Failure

Never fails.

Example

Comments

The function conjuncts is equivalent to the standard function strip_conj, so called in order to be consistent with all the other strip_ routines. Because conjuncts splits both

the left and right sides of a conjunction, this operation is not the inverse of list_mk_conj. It may be useful to introduce list_dest_conj for splitting only the right tails of a conjunction.

See also

list_mk_conj, dest_conj.

CONJUNCTS

CONJUNCTS : (thm -> thm list)

Synopsis

Recursively splits conjunctions into a list of conjuncts.

Description

Flattens out all conjuncts, regardless of grouping. Returns a singleton list if the input theorem is not a conjunction.

A |- t1 /\ t2 /\ ... /\ tn ------ CONJUNCTS A |- t1 A |- t2 ... A |- tn

Failure

Never fails.

Example

Suppose the identifier th is bound to the theorem:

A |- (x /\ y) /\ z /\ w

Application of CONJUNCTS to th returns the following list of theorems:

[A |- x; A |- y; A |- z; A |- w] : thm list

See also

BODY_CONJUNCTS, CONJ_LIST, LIST_CONJ, CONJ, CONJUNCT1, CONJUNCT2, CONJ_PAIR.

CONJUNCTS_CONV

CONJUNCTS_CONV : ((term # term) -> thm)

Synopsis

Prove equivalence under idempotence, symmetry and associativity of conjunction.

Description

CONJUNCTS_CONV takes a pair of terms "t1" and "t2", and proves |-t1| = t2 if t1 and t2 are equivalent up to idempotence, symmetry and associativity of conjunction. That is, if t1 and t2 are two (different) arbitrarily-nested conjunctions of the same set of terms, then CONJUNCTS_CONV (t1,t2) returns |-t1| = t2. Otherwise, it fails.

Failure

Fails if t1 and t2 are not equivalent, as described above.

Example

#CONJUNCTS_CONV ("(P /\ Q) /\ R", "R /\ (Q /\ R) /\ P");; |- (P /\ Q) /\ R = R /\ (Q /\ R) /\ P

Uses

Used to reorder a conjunction. First sort the conjuncts in a term t1 into the desired order (e.g. lexicographic order, for normalization) to get a new term t2, then call CONJUNCTS_CONV(t1,t2).

Comments

This is not a true conversion, so perhaps it ought to be called something else.

See also

CONJ_SET_CONV.

CONJUNCTS_THEN

CONJUNCTS_THEN : thm_tactical

Synopsis

Applies a theorem-tactic to each conjunct of a theorem.

Description

CONJUNCTS_THEN takes a theorem-tactic f, and a theorem t whose conclusion must be a conjunction. CONJUNCTS_THEN breaks t into two new theorems, t1 and t2 which are

CONJUNCT1 and CONJUNCT2 of t respectively, and then returns a new tactic: f t1 THEN f t2. That is,

```
CONJUNCTS_THEN f (A |-1|/r) = f (A |-1) THEN f (A |-r)
```

so if

```
A1 ?- t1A2 ?- t2====== f (A |- 1)====== f (A |- r)A2 ?- t2A3 ?- t3
```

then

```
A1 ?- t1
======== CONJUNCTS_THEN f (A |- 1 /\ r)
A3 ?- t3
```

Failure

CONJUNCTS_THEN f will fail if applied to a theorem whose conclusion is not a conjunction.

Comments

CONJUNCTS_THEN f (A |- u1 / | ... / | un) results in the tactic:

f (A |- u1) THEN f (A |- u2 /\ ... /\ un)

Unfortunately, it is more likely that the user had wanted the tactic:

f (A |- u1) THEN ... THEN f(A |- un)

Such a tactic could be defined as follows:

```
let CONJUNCTS_THENL (f:thm_tactic) thm =
    itlist $THEN (map f (CONJUNCTS thm)) ALL_TAC;;
```

or by using REPEAT_TCL.

See also

CONJUNCT1, CONJUNCT2, CONJUNCTS, CONJ_TAC, CONJUNCTS_THEN2, STRIP_THM_THEN.

CONJUNCTS_THEN2

CONJUNCTS_THEN2 : (thm_tactic -> thm_tactic -> thm_tactic)

Synopsis

Applies two theorem-tactics to the corresponding conjuncts of a theorem.

Description

CONJUNCTS_THEN2 takes two theorem-tactics, f1 and f2, and a theorem t whose conclusion must be a conjunction. CONJUNCTS_THEN2 breaks t into two new theorems, t1 and t2 which are CONJUNCT1 and CONJUNCT2 of t respectively, and then returns the tactic f1 t1 THEN f2 t2. Thus

```
CONJUNCTS_THEN2 f1 f2 (A |-1|/r) = f1 (A |-1) THEN f2 (A |-r)
```

so if

A1 ?- t1A2 ?- t2========f1 (A |-1)=======A2 ?- t2A3 ?- t3

then

```
A1 ?- t1
======= CONJUNCTS_THEN2 f1 f2 (A |- 1 /\ r)
A3 ?- t3
```

Failure

CONJUNCTS_THEN f will fail if applied to a theorem whose conclusion is not a conjunction.

Comments

The system shows the type as (thm_tactic -> thm_tactical).

Uses

The construction of complex tacticals like CONJUNCTS_THEN.

See also

CONJUNCT1, CONJUNCT2, CONJUNCTS, CONJ_TAC, CONJUNCTS_THEN2, STRIP_THM_THEN.

CONJ_DISCH

CONJ_DISCH : (term \rightarrow thm \rightarrow thm)

Synopsis

Discharges an assumption and conjoins it to both sides of an equation.

Description

Given an term t and a theorem A |-t1 = t2, which is an equation between boolean terms, CONJ_DISCH returns A $- \{t\} |-(t / t1) = (t / t2)$, i.e. conjoins t to both sides of the equation, removing t from the assumptions if it was there.

A |- t1 = t2 ----- CONJ_DISCH "t" A - {t} |- t /\ t1 = t /\ t2

Failure

Fails unless the theorem is an equation, both sides of which, and the term provided are of type bool.

See also

CONJ_DISCHL.

CONJ_DISCHL

CONJ_DISCHL : (term list -> thm -> thm)

Synopsis

Conjoins multiple assumptions to both sides of an equation.

Description

Given a term list [t1;...;tn] and a theorem whose conclusion is an equation between boolean terms, CONJ_DISCHL conjoins all the terms in the list to both sides of the equation, and removes any of the terms which were in the assumption list.

A |- s = t ----- CONJ_DISCHL A - {t1,...,tn} |- (t1/\.../\tn/\s) = (t1/\.../\tn/\t) ["t1";...;"tn"]

Failure

Fails unless the theorem is an equation, both sides of which, and all the terms provided, are of type bool.

See also

CONJ_DISCH.

CONJ_LIST

CONJ_LIST : (int -> thm -> thm list)

Synopsis

Extracts a list of conjuncts from a theorem (non-flattening version).

Description

CONJ_LIST is the proper inverse of LIST_CONJ. Unlike CONJUNCTS which recursively splits as many conjunctions as possible both to the left and to the right, CONJ_LIST splits the top-level conjunction and then splits (recursively) only the right conjunct. The integer argument is required because the term tn may itself be a conjunction. A list of n theorems is returned.

A |- t1 /\ (t2 /\ (... /\ tn)...) ------ CONJ_LIST n (A |- t1 /\ ... /\ tn) A |- t1 A |- t2 ... A |- tn

Failure

Fails if the integer argument (n) is less than one, or if the input theorem has less than n conjuncts.

Example

Suppose the identifier th is bound to the theorem:

A |- (x /\ y) /\ z /\ w

Here are some applications of CONJ_LIST to th:

```
#CONJ_LIST 0 th;;
evaluation failed CONJ_LIST
#CONJ_LIST 1 th;;
[A \mid - (x / \setminus y) / \setminus z / \setminus w] : thm list
#CONJ_LIST 2 th;;
[A \mid - x / \setminus y; A \mid - z / \setminus w] : thm list
#CONJ_LIST 3 th;;
[A \mid - x / \setminus y; A \mid - z; A \mid - w] : thm list
#CONJ_LIST 4 th;;
evaluation failed CONJ_LIST
```

See also

BODY_CONJUNCTS, LIST_CONJ, CONJUNCTS, CONJ, CONJUNCT1, CONJUNCT2, CONJ_PAIR.

CONJ_PAIR

CONJ_PAIR : (thm -> (thm # thm))

Synopsis

Extracts both conjuncts of a conjunction.

Description

A |- t1 /\ t2 ----- CONJ_PAIR A |- t1 A |- t2

The two resultant theorems are returned as a pair.

Failure

Fails if the input theorem is not a conjunction.

84

See also

BODY_CONJUNCTS, CONJUNCT1, CONJUNCT2, CONJ, LIST_CONJ, CONJ_LIST, CONJUNCTS.

CONJ_SET_CONV

CONJ_SET_CONV : (term list -> term list -> thm)

Synopsis

Proves the equivalence of the conjunctions of two equal sets of terms.

Description

The arguments to CONJ_SET_CONV are two lists of terms [t1;...;tn] and [u1;...;um]. If these are equal when considered as sets, that is if the sets

 $\{\texttt{t1},\ldots,\texttt{tn}\}$ and $\{\texttt{u1},\ldots,\texttt{um}\}$

are equal, then CONJ_SET_CONV returns the theorem:

|- (t1 /\ ... /\ tn) = (u1 /\ ... /\ um)

Otherwise CONJ_SET_CONV fails.

Failure

CONJ_SET_CONV [t1;...;tn] [u1;...;um] fails if [t1,...,tn] and [u1,...,um], regarded as sets of terms, are not equal. Also fails if any ti or ui does not have type bool.

Uses

Used to order conjuncts. First sort a list of conjuncts 11 into the desired order to get a new list 12, then call CONJ_SET_CONV 11 12.

Comments

This is not a true conversion, so perhaps it ought to be called something else.

See also

CONJUNCTS_CONV.

CONJ_TAC

CONJ_TAC : tactic

Synopsis

Reduces a conjunctive goal to two separate subgoals.

Description

When applied to a goal A ?- t1 / t2, the tactic CONJ_TAC reduces it to the two subgoals corresponding to each conjunct separately.

A ?- t1 /\ t2 ======= CONJ_TAC A ?- t1 A ?- t2

Failure

Fails unless the conclusion of the goal is a conjunction.

See also

STRIP_TAC.

constants

```
constants : (string -> term list)
```

Synopsis

Returns a list of the constants defined in a named theory.

Description

The call

constants 'thy'

where thy is an ancestor theory (the special string '-' means the current theory), returns a list of all the constants in that theory.

Failure

Fails if the named theory does not exist, or is not an ancestor of the current theory.

Example

```
#constants 'combin';;
["I"; "S"; "K"; "$o"] : term list
```

See also

axioms, binders, definitions, infixes, theorems

86

CONTR

CONTR : (term -> thm -> thm)

Synopsis

Implements the intuitionistic contradiction rule.

Description

When applied to a term t and a theorem A \mid - F, the inference rule CONTR returns the theorem A \mid - t.

A |- F ----- CONTR "t" A |- t

Failure

Fails unless the term has type bool and the theorem has F as its conclusion.

See also

CCONTR, CONTRAPOS, CONTR_TAC, NOT_ELIM.

CONTRAPOS

CONTRAPOS : (thm -> thm)

Synopsis

Deduces the contrapositive of an implication.

Description

When applied to a theorem A |-s => t, the inference rule CONTRAPOS returns its contrapositive, A $|-\tau t => \tau$ s.

A |- s ==> t ----- CONTRAPOS A |- ~t ==> ~s

Failure

Fails unless the theorem is an implication.

See also

CCONTR, CONTR, CONTRAPOS_CONV, NOT_ELIM.

CONTRAPOS_CONV

CONTRAPOS_CONV : conv

Synopsis

Proves the equivalence of an implication and its contrapositive.

Description

When applied to an implication P ==> Q, the conversion CONTRAPOS_CONV returns the theorem:

|-(P ==> Q) = (~Q ==> ~P)

Failure

Fails if applied to a term that is not an implication.

See also

CONTRAPOS.

CONTR_TAC

CONTR_TAC : thm_tactic

Synopsis

Solves any goal from contradictory theorem.

Description

When applied to a contradictory theorem A' |- F, and a goal A ?- t, the tactic CONTR_TAC completely solves the goal. This is an invalid tactic unless A' is a subset of A.

A ?- t ======= CONTR_TAC (A' |- F)

Failure

Fails unless the theorem is contradictory, i.e. has F as its conclusion.

See also

CHECK_ASSUME_TAC, CONTR, CCONTR, CONTRAPOS, NOT_ELIM.

CONV_RULE

CONV_RULE : (conv -> thm -> thm)

Synopsis

Makes an inference rule from a conversion.

Description

If c is a conversion, then CONV_RULE c is an inference rule that applies c to the conclusion of a theorem. That is, if c maps a term "t" to the theorem |-t = t', then the rule CONV_RULE c infers |-t' from the theorem |-t. More precisely, if c "t" returns A' |-t = t', then:

A |- t ----- CONV_RULE c A u A' |- t'

Note that if the conversion c returns a theorem with assumptions, then the resulting inference rule adds these to the assumptions of the theorem it returns.

Failure

CONV_RULE c th fails if c fails when applied to the conclusion of th. The function returned by CONV_RULE c will also fail if the ML function c:term->thm is not, in fact, a conversion (i.e. a function that maps a term t to a theorem |-t = t').

See also

CONV_TAC, RIGHT_CONV_RULE.

CONV_TAC

CONV_TAC : (conv -> tactic)

Synopsis

Makes a tactic from a conversion.

Description

If c is a conversion, then CONV_TAC c is a tactic that applies c to the goal. That is, if c maps a term "g" to the theorem |-g = g', then the tactic CONV_TAC c reduces a goal g to the subgoal g'. More precisely, if c "g" returns A' |-g = g', then:

A ?- g ====== CONV_TAC c A ?- g'

Note that the conversion c should return a theorem whose assumptions are also among the assumptions of the goal (normally, the conversion will returns a theorem with no assumptions). CONV_TAC does not fail if this is not the case, but the resulting tactic will be invalid, so the theorem ultimately proved using this tactic will have more assumptions than those of the original goal.

Failure

CONV_TAC c applied to a goal A ?- g fails if c fails when applied to the term g. The function returned by CONV_TAC c will also fail if the ML function c:term->thm is not, in fact, a conversion (i.e. a function that maps a term t to a theorem |-t = t').

Uses

CONV_TAC is used to apply simplifications that can't be expressed as equations (rewrite rules). For example, a goal can be simplified by beta-reduction, which is not expressible as a single equation, using the tactic

```
CONV_TAC(DEPTH_CONV BETA_CONV)
```

The conversion BETA_CONV maps a beta-redex "(\x.u)v" to the theorem

|-(x.u)v = u[v/x]

and the ML expression (DEPTH_CONV BETA_CONV) evaluates to a conversion that maps a term "t" to the theorem |- t=t' where t' is obtained from t by beta-reducing all beta-redexes in t. Thus CONV_TAC(DEPTH_CONV BETA_CONV) is a tactic which reduces betaredexes anywhere in a goal.

See also

CONV_RULE.

current_theory

```
current_theory : (void -> string)
```

Synopsis

Returns the name of the current theory.

Description

Within a HOL session there is always a current theory. It is the theory represented by the current theory segment together with its ancestry. A call of current_theory() returns the name of the current theory. Initially HOL has current theory scratch.

Failure

Never fails.

See also

export_theory, new_theory, print_theory.

current_trace

current_trace : string -> int

Synopsis

Returns the current value of the tracing variable specified.

Failure

Fails if the name given is not associated with a registered tracing variable.

See also

register_trace, reset_trace, reset_traces, trace, traces.

curry

curry : (('a * 'b) -> 'c) -> 'a -> 'b -> 'c

Synopsis

Converts a function on a pair to a corresponding curried function.

Description

The application curry f returns x y. f(x,y), so that

curry f x y = f(x,y)

Failure

Never fails.

Example

```
- val increment = curry op+ 1;
> val it = increment = fn : int -> int
- increment 6;
> val it = 7 : int
```

See also

uncurry.

define_new_type_bijections

```
define_new_type_bijections :
    {name :string, ABS :string, REP :string, tyax :thm} -> thm
```

Synopsis

Introduces abstraction and representation functions for a defined type.

Description

The result of making a type definition using new_type_definition is a theorem of the following form:

```
|- ?rep:nty->ty. TYPE_DEFINITION P rep
```

which asserts only the existence of a bijection from the type it defines (in this case, nty) to the corresponding subset of an existing type (here, ty) whose characteristic function is specified by P. To automatically introduce constants that in fact denote this bijection and its inverse, the ML function define_new_type_bijections is provided.

name is the name under which the constant definition (a constant specification, in fact)
made by define_new_type_bijections will be stored in the current theory segment. tyax

92

must be a definitional axiom of the form returned by new_type_definition. ABS and REP are the user-specified names for the two constants that are to be defined. These constants are defined so as to denote mutually inverse bijections between the defined type, whose definition is given by tyax, and the representing type of this defined type.

If th is a theorem of the form returned by new_type_definition:

|- ?rep:newty->ty. TYPE_DEFINITION P rep

then evaluating:

define_new_type_bijections{name="name",ABS="abs",REP="rep",tyax=th} th

automatically defines two new constants abs:ty->newty and rep:newty->ty such that:

|- (!a. abs(rep a) = a) /\ (!r. P r = (rep(abs r) = r))

This theorem, which is the defining property for the constants abs and rep, is stored under the name name in the current theory segment. It is also the value returned by define_new_type_bijections. The theorem states that abs is the left inverse of rep and, for values satisfying P, that rep is the left inverse of abs.

Failure

A call to define_new_type_bijections{name=s1,ABS=s2,REP=s3,tyax=th} fails if th is not a theorem of the form returned by new_type_definition, or if either s2 or s3 is already the name of a constant in the current theory, or there already exists a constant definition, constant specification, type definition or axiom named s1 in the current theory, or HOL is not in draft mode.

See also

new_type_definition, prove_abs_fn_one_one, prove_abs_fn_onto, prove_rep_fn_one_one, prove_rep_fn_onto.

define_type

Synopsis

Automatically defines a user-specified concrete recursive data type.

Description

The ML function define_type automatically defines any required concrete recursive type in the logic. The name argument is the name under which the results of making the definition will be stored in the current theory segment. The type_spec argument is a user-supplied specification of the type to be defined. This specification (explained below) simply states the names of the new type's constructors and the logical types of their arguments. The fixities argument gives the parsing status of the introduced constants: it may be Prefix, Binder, or Infix <positive int>. The theorem returned by define_type is an automatically-proved abstract characterization of the concrete data type described by this specification.

The type_spec argument to define_type must be a quotation of the form:

```
'op = C1 of ty => ... => ty | C2 of ty=> ...=>ty | ... | Cn of ty=> ... =>ty'
```

where op is the name of the type constant or type operator to be defined, C1, ..., Cn are identifiers, and each ty is either a (logical) type expression valid in the current theory (in which case ty must not contain op) or just the identifier 'op' itself.

A quotation of this form describes an n-ary type operator op, where n is the number of distinct type variables in the types ty on the right hand side of the equation. If n is zero then op is a type constant; otherwise op is an n-ary type operator. The type described by the specification has n distinct constructors C1, ..., Cn. Each constructor Ci is a function that takes arguments whose types are given by the associated type expressions ty in the specification. If one or more of the type expressions ty is the type op itself, then the equation specifies a recursive data type. In any specification, at least one constructor must be non-recursive, i.e. all its arguments must have types which already exist in the current theory.

Given a type specification of the form described above, define_type makes an appropriate type definition for the type operator op. It then makes appropriate definitions for the constants C1, ..., Cn, and automatically proves a theorem that states an abstract characterization of the newly-defined type op. This theorem, which is stored in the current theory segment under the name supplied as the first argument and also returned by define_type, has the form of a 'primitive recursion theorem' for the concrete type op (see the examples given below). This property provides an abstract characterization of the type op which is both succinct and complete, in the sense that it completely determines the structure of the values of op up to isomorphism.

Failure

Evaluating

fails if HOL is not in draft mode; if op is already the name of a type constant or type operator in the current theory; if the supplied constant names C1, ..., Cn are not distinct; if any one of C1, ..., Cn is already a constant in the current theory or is not an allowed name for a constant; if ABS_op or REP_op are already constants in the current theory; if there is already an axiom, definition, constant specification or type definition stored under either the name op_TY_DEF or the name op_ISO_DEF in the current theory segment; if there is already a theorem stored under the name 'name' in the current theory segment; or (finally) if the input type specification does not conform in any other respect to the syntax described above.

Example

The following call to define_type defines tri to be a simple enumerated type with exactly three distinct values:

The theorem returned is a degenerate 'primitive recursion' theorem for the concrete type tri. An example of a recursive type that can be defined using define_type is a type of binary trees:

The theorem returned by define_type in this case asserts the unique existence of functions defined by primitive recursion over labelled binary trees.

Note that the type being defined may not occur as a proper subtype in any of the

types of the arguments of the constructors:

In this example, there is an error because ty occurs within the type expression (ty -> ty).

Comments

The "=>" that may be used in type specifications is merely a delimiter that shows a constructor to be Curried. It must occur at the "top-level" in the argument list to a constructor. i.e., parsing of the type specification will fail if the "=>" occurs underneath an existing type constructor.

See also

INDUCT_THEN, new_recursive_definition, prove_cases_thm,
prove_constructors_distinct, prove_constructors_one_one, prove_induction_thm,
prove_rec_fn_exists.
```

DEF_EXISTS_RULE

```
DEF_EXISTS_RULE : (term -> thm)
```

Synopsis

Proves that a function defined by a definitional equation exists.

Description

This rule accepts a term of the form "c = ..." or "f x1 ... xn = ...", the variables of which may be universally quantified, and returns an existential theorem. The resulting theorem is typically used for generating HOL specifications.

Failure

DEF_EXISTS_RULE fails if the definition is not an equation, if there is any variable in the right-hand side which does not occur in the left-hand side, if the definition is recursive, if there is a free type variable, or if the name being defined by the function is not allowed.

Example

The effect of this rule can be understood more clearly through an example:

```
#DEF_EXISTS_RULE "max a b = ((a < b) => b | a)" ;;
|- ?max. !a b. max a b = (a < b => b | a)
```

Comments

In later versions of HOL this function may be made internal.

See also new_definition, new_gen_definition, new_specification.

delete_restriction

```
delete_restriction : (string -> unit)
```

Synopsis

Removes a restriction semantics from a binder.

Description

Recall that if B is a binder and RES_B a constant then

```
associate_restriction("B", "RES_B")
```

will cause the parser and pretty-printer to support:

---- parse ----> Bv::P. B RES_B P (\v. B) <---- print ----

This behaviour may be disabled by calling delete_restriction with the binder name ("B" in this example).

Failure

Fails if you attempt to remove one of the builtin restrictions. These are associated with the binders

["!","?","@","\\"]

Also fails if the named binder is not restricted, i.e., found as the first member of a pair on the list returned by binder_restrictions.

Example

```
associate_restriction("DURING","RES_DURING");
() : unit
-- 'DURING x::(m,n). p x'--;
(-- 'DURING x ::(m,n). p x'--) : term
- delete_restriction "DURING";
() : unit
-- 'DURING x::(m,n). p x'--;
Exception raised at Parse_support.restr_binder:
no restriction associated with "DURING"
```

See also associate_restrictions, binder_restrictions

DEPTH_CONV

DEPTH_CONV : (conv -> conv)

Synopsis

Applies a conversion repeatedly to all the sub-terms of a term, in bottom-up order.

Description

DEPTH_CONV c tm repeatedly applies the conversion c to all the subterms of the term tm, including the term tm itself. The supplied conversion is applied repeatedly (zero or more times, as is done by REPEATC) to each subterm until it fails. The conversion is applied to subterms in bottom-up order.

Failure

DEPTH_CONV c tm never fails but can diverge if the conversion c can be applied repeatedly to some subterm of tm without failing.

Example

The following example shows how DEPTH_CONV applies a conversion to all subterms to

which it applies:

```
#DEPTH_CONV BETA_CONV "(\x. (\y. y + x) 1) 2";;
|- (\x. (\y. y + x)1)2 = 1 + 2
```

Here, there are two beta-redexes in the input term, one of which occurs within the other. DEPTH_CONV BETA_CONV applies beta-conversion to innermost beta-redex (y. y + x) 1 first. The outermost beta-redex is then (x. 1 + x) 2, and beta-conversion of this redex gives 1 + 2.

Because DEPTH_CONV applies a conversion bottom-up, the final result may still contain subterms to which the supplied conversion applies. For example, in:

#DEPTH_CONV BETA_CONV "(\f x. (f x) + 1) (\y.y) 2";; |- (\f x. (f x) + 1)(\y. y)2 = ((\y. y)2) + 1

the right-hand side of the result still contains a beta-redex, because the redex "(y,y)2" is introduced by virtue an application of BETA_CONV higher-up in the structure of the input term. By contrast, in the example:

```
#DEPTH_CONV BETA_CONV "(\f x. (f x)) (\y.y) 2";;
|- (\f x. f x)(\y. y)2 = 2
```

all beta-redexes are eliminated, because DEPTH_CONV repeats the supplied conversion (in this case, BETA_CONV) at each subterm (in this case, at the top-level term).

Uses

If the conversion c implements the evaluation of a function in logic, then DEPTH_CONV c will do bottom-up evaluation of nested applications of it. For example, the conversion ADD_CONV implements addition of natural number constants within the logic. Thus, the effect of:

#DEPTH_CONV ADD_CONV "(1 + 2) + (3 + 4 + 5)";; |- (1 + 2) + (3 + (4 + 5)) = 15

is to compute the sum represented by the input term.

Comments

The implementation of this function uses failure to avoid rebuilding unchanged subterms. That is to say, during execution the failure string 'QCONV' may be generated and later trapped. The behaviour of the function is dependent on this use of failure. So, if the conversion given as an argument happens to generate a failure with string 'QCONV', the operation of DEPTH_CONV will be unpredictable.

See also

ONCE_DEPTH_CONV, REDEPTH_CONV, TOP_DEPTH_CONV.

dest_abs

dest_abs : term -> {Bvar :term, Body :term}

Synopsis

Breaks apart an abstraction into abstracted variable and body.

Description

dest_abs is a term destructor for abstractions: dest_abs (--'\var. t'--) returns Bvar = var, Body = t.

Failure

Fails with

See also

```
mk_abs, is_abs, dest_var, dest_const, dest_comb, strip_abs.
```

$dest_comb$

dest_comb : term -> {Rator :term, Rand :term}

Synopsis

Breaks apart a combination (function application) into rator and rand.

Description

dest_comb is a term destructor for combinations:

dest_comb (--'t1 t2'--)

returns Rator = t1, Rand = t2.

Failure

Fails with

See also

```
mk_comb, is_comb, dest_var, dest_const, dest_abs, strip_comb.
```

dest_cond

dest_cond : term -> {cond :term, larm :term, rarm :term}

Synopsis

Breaks apart a conditional into the three terms involved.

Description

dest_cond is a term destructor for conditionals:

dest_cond (--'t => t1 | t2'--)

returns cond = t, larm = t1, rarm = t2.

Failure

Fails with

if term is not a conditional.

See also mk_cond, is_cond.

dest_conj

dest_conj : term -> {conj1 :term, conj2 :term}

Synopsis

Term destructor for conjunctions.

Description

dest_conj(--'t1 /\ t2'--) returns conj1 = t1, conj2 = t2.

Failure

Fails with

if term is not a conjunction.

See also

mk_conj, is_conj.

dest_cons

dest_cons : term -> {hd :term, tl :term}

Synopsis

Breaks apart a 'CONS pair' into head and tail.

Description

dest_cons is a term destructor for 'CONS pairs'. When applied to a term representing a nonempty list -- '[t;t1;...;tn]'-- (which is equivalent to -- 'CONS t [t1;...;tn]'--), it returns the pair of terms hd = t, tl = -'[t1;...;tn]'-.

Failure

Fails with

if the term is not a non-empty list.

See also

mk_cons, is_cons, mk_list, dest_list, is_list.

dest_const

dest_const : term -> {Name :string, Ty :hol_type}

Synopsis

Breaks apart a constant into name and type.

Description

dest_const is a term destructor for constants:

```
dest_const (-- 'const:ty'--)
```

returns Name = "const", Ty = (==:ty'==).

Failure

Fails with

See also

mk_const, is_const, dest_var, dest_comb, dest_abs.

dest_disj

dest_disj : term -> {disj1 :term, disj2 :term}

Synopsis

Term destructor for disjunctions.

Description

dest_disj(--'t1 /\ t2'--) returns disj1 = t1, disj2 = t2.

Failure

Fails with

if term is not a disjunction.

See also

mk_disj, is_disj.

dest_eq

dest_eq : term -> {lhs :term, rhs :term}

Synopsis

Term destructor for equality.

Description

 $dest_eq(--'t1 = t2'--)$ returns lhs = t1, rhs = t2.

Failure

Fails with

See also

mk_eq, is_eq.

dest_exists

dest_exists : term -> {Bvar :term, Body :term}

Synopsis

Breaks apart a existentially quantified term into quantified variable and body.

Description

dest_exists is a term destructor for existential quantification: dest_exists (--'!var. t'--)
returns Bvar = var, Body = t.

Failure

Fails with

if term is not a existential quantification.

See also

mk_exists, is_exists, strip_exists.

dest_forall

dest_forall : term -> {Bvar :term, Body :term}

Synopsis

Breaks apart a universally quantified term into quantified variable and body.

Description

dest_forall is a term destructor for universal quantification: dest_forall (--'!var. t'--) returns Bvar = var, Body = t.

Failure

Fails with

if term is not a universal quantification.

See also

mk_forall, is_forall, strip_forall.

dest_imp

dest_imp : term -> {ant :term, conseq :term}

Synopsis

Breaks apart an implication (or negation) into antecedent and consequent.

Description

 $dest_imp$ is a term destructor for implications, which treats negations as implications with consequent F. Thus

```
dest_imp (--'t1 ==> t2'--)
```

returns

 $\{ant = t1, conseq = t2\}$

and also

dest_imp (--'~t'--)

returns

 $\{ant = t, conseq = (--'F'--)\}$

Failure

Fails with

if term is neither an implication nor a negation.

Comments

Destructs negations for increased functionality of HOL-style resolution.

See also

mk_imp, is_imp, strip_imp.

dest_let

dest_let : term -> {func :term, arg :term}

Synopsis

Breaks apart a let-expression.

Description

dest_let is a term destructor for general let-expressions: dest_let (--'LET f x'--) returns func = f, arg = x.

Example

```
- dest_let (--'LET ($= 1) 2'--);
{func=(--'$= 1'--), arg=(--'2'--)}
- dest_let (--'let x = 2 in (x = 1)'--);
{func=(--'\x. x = 1'--), arg=(--'2'--)}
```

Failure

Fails with

if term is not a let-expression or of the more general -- 'LET f x'-- form.

See also mk_let, is_let.

dest_list

dest_list : term -> {els :term list, ty :type}

Synopsis

Iteratively breaks apart a list term.

Description

dest_list is a term destructor for lists: dest_list (-- '[t1;...;tn]:ty list '--) returns
els = [t1;...;tn], ty = ty.

Failure

Fails with

if the term is not a list.

See also

mk_list, is_list, mk_cons, dest_cons, is_cons.

dest_neg

dest_neg : (term -> term)

Synopsis

Breaks apart a negation, returning its body.

Description

dest_neg is a term destructor for negations: dest_neg "~t" returns "t".

Failure

Fails with dest_neg if term is not a negation.

See also

mk_neg, is_neg.

dest_pabs

dest_pabs : term -> {varstruct : term, body :term}

Synopsis

Breaks apart a paired abstraction into abstracted varstruct and body.

Description

dest_pabs is a term destructor for paired abstractions: dest_pabs (--' (v1..(.)..vn). t'--) returns varstruct = -'(v1..(.)..vn)'-, body = t.

Failure

Fails with

unless the term is a paired abstraction.

See also

mk_pabs, is_pabs, dest_abs, dest_var, dest_const, dest_comb.

dest_pair

dest_pair : term -> {fst :term, snd :term}

Synopsis

Breaks apart a pair into two separate terms.

Description

dest_pair is a term destructor for pairs: dest_pair (-- (t1,t2) -) returns fst = t1, snd = t2.

Failure

Fails with

if term is not a pair.

See also

mk_pair, is_pair, strip_pair.

dest_select

dest_select : term -> {Bvar :term, Body :term}

Synopsis

Breaks apart a choice term into selected variable and body.

Description

dest_select is a term destructor for choice terms:

```
dest_select (--'@var. t'--)
```

returns Bvar = var, Body = t.

Failure

Fails with

```
HOL_ERR{origin_structure = "Dsyntax", origin_function = "dest_select",
    message = "not a @"}
```

if term is not an epsilon-term.

See also

mk_select, is_select.

dest_thm

dest_thm : (thm -> goal)

Synopsis

Breaks a theorem into assumption list and conclusion.

Description

dest_thm (t1,...,tn |- t) returns (["t1";...;"tn"],"t").

Failure

Never fails.

Example

#dest_thm (ASSUME "p=T");; (["p = T"], "p = T") : goal

See also

concl, hyp.

dest_type

dest_type : type -> {Tyop :string, Args :hol_type list}

Synopsis

Breaks apart a type (other than a variable type).

Description

```
dest_type(==':(ty1,...,tyn)op'==) returns
Tyop = "op", Args = [ty1,...,tyn].
```

Example

```
- dest_type (==':bool'==);
{Tyop = "bool", Args = []}
- dest_type (==':bool list'==);
{Tyop = "list", Args = [==':bool'==]}
- dest_type (==':num -> bool'==);
```

{Tyop = "fun", Args = [==':num'==; ==':bool'==]}

Failure

Fails with

if the type is a type variable.

See also

mk_type, dest_vartype.

dest_var

dest_var : term -> {Name :string, Ty: hol_type}

Synopsis

Breaks apart a variable into name and type.

Description

dest_var (--'var:ty'--) returns Name = "var", Ty = (==':ty'==).

Failure

Fails with

See also

mk_var, is_var, dest_const, dest_comb, dest_abs.

dest_vartype

dest_vartype : (type -> string)

Synopsis

Breaks a type variable down to its name.

Description

dest_vartype ":*..." returns '*...'.

Failure

Fails with dest_vartype if the type is not a type variable.

Example

#dest_vartype ":* -> bool";;
evaluation failed dest_vartype

See also
mk_vartype, is_vartype, dest_type.

DISCARD_TAC

DISCARD_TAC : thm_tactic

Synopsis

Discards a theorem already present in a goal's assumptions.

Description

When applied to a theorem A' |- s and a goal, DISCARD_TAC checks that s is simply T (true), or already exists (up to alpha-conversion) in the assumption list of the goal. In either case, the tactic has no effect. Otherwise, it fails.

```
A ?- t
======= DISCARD_TAC (A' |- s)
A ?- t
```

Failure

Fails if the above conditions are not met, i.e. the theorem's conclusion is not T or already in the assumption list (up to alpha-conversion).

See also

POP_ASSUM, POP_ASSUM_LIST.

disch

```
disch : ((term * term list) -> term list)
```

Synopsis

Removes those elements of a list of terms that are alpha equivalent to a given term.

Description

Given a pair ("t",tl), disch removes those elements of tl that are alpha equivalent to "t".

Example

```
disch (Term'\x:bool.T', [Term'A = T',Term'B = 3',Term'\y:bool.T']);
['A = T','B = 3'] : term list
```

See also

filter.

DISCH

DISCH : (term \rightarrow thm \rightarrow thm)

Synopsis

Discharges an assumption.

Description

A |- t ----- DISCH "u" A - {u} |- u ==> t

Failure

DISCH will fail if "u" is not boolean.

Comments

The term "u" need not be a hypothesis. Discharging "u" will remove all identical and alpha-equivalent hypotheses.

See also

```
DISCH_ALL, DISCH_TAC, DISCH_THEN, FILTER_DISCH_TAC, FILTER_DISCH_THEN, NEG_DISCH, STRIP_TAC, UNDISCH, UNDISCH_ALL, UNDISCH_TAC.
```

DISCH_ALL

DISCH_ALL : (thm -> thm)

Synopsis

Discharges all hypotheses of a theorem.

Description

A1, ..., An |- t ----- DISCH_ALL |- A1 ==> ... ==> An ==> t

Failure

DISCH_ALL will not fail if there are no hypotheses to discharge, it will simply return the theorem unchanged.

Comments

Users should not rely on the hypotheses being discharged in any particular order. Two or more alpha-convertible hypotheses will be discharged by a single implication; users should not rely on which hypothesis appears in the implication.

See also

DISCH, DISCH_TAC, DISCH_THEN, NEG_DISCH, FILTER_DISCH_TAC, FILTER_DISCH_THEN, STRIP_TAC, UNDISCH, UNDISCH_ALL, UNDISCH_TAC.

DISCH_TAC

DISCH_TAC : tactic

Synopsis

Moves the antecedent of an implicative goal into the assumptions.

Description

A ?- u ==> v ======= DISCH_TAC A u {u} ?- v

Note that DISCH_TAC treats "~u" as "u ==> F", so will also work when applied to a goal with a negated conclusion.

Failure

DISCH_TAC will fail for goals which are not implications or negations.

Uses

Solving goals of the form "u == v" by rewriting "v" with "u", although the use of DISCH_THEN is usually more elegant in such cases.

Comments

If the antecedent already appears in the assumptions, it will be duplicated.

See also

```
DISCH, DISCH_ALL, DISCH_THEN, FILTER_DISCH_TAC, FILTER_DISCH_THEN, NEG_DISCH, STRIP_TAC, UNDISCH, UNDISCH_ALL, UNDISCH_TAC.
```

DISCH_THEN

Synopsis

Undischarges an antecedent of an implication and passes it to a theorem-tactic.

Description

DISCH_THEN removes the antecedent and then creates a theorem by ASSUMEing it. This new theorem is passed to the theorem-tactic given as DISCH_THEN's argument. The consequent tactic is then applied. Thus:

DISCH_THEN f (asl,"t1 ==> t2") = f(ASSUME "t1")(asl,"t2")

For example, if

A ?- t ======= f (ASSUME "u") B ?- v

then

A ?- u ==> t ========== DISCH_THEN f B ?- v

Note that DISCH_THEN treats "~u" as "u ==> F".

Failure

DISCH_THEN will fail for goals which are not implications or negations.

Example

The following shows how DISCH_THEN can be used to preprocess an antecedent before adding it to the assumptions.

A ?- (x = y) ==> t ================ DISCH_THEN (ASSUME_TAC o SYM) A u {y = x} ?- t

In many cases, it is possible to use an antecedent and then throw it away:

See also

DISCH, DISCH_ALL, DISCH_TAC, NEG_DISCH, FILTER_DISCH_TAC, FILTER_DISCH_THEN, STRIP_TAC, UNDISCH, UNDISCH_ALL, UNDISCH_TAC.

DISJ1

DISJ1 : (thm \rightarrow term \rightarrow thm)

Synopsis

Introduces a right disjunct into the conclusion of a theorem.

Description

A |- t1 ----- DISJ1 (A |- t1) "t2" A |- t1 \/ t2

Failure

Fails unless the term argument is boolean.

Example

#DISJ1 TRUTH "F";;
|- T \/ F

Comments

The system shows the type of DISJ1 as (thm -> conv).

See also DISJ1_TAC, DISJ2, DISJ2_TAC, DISJ_CASES.

DISJ1_TAC

DISJ1_TAC : tactic

Synopsis

Selects the left disjunct of a disjunctive goal.

Description

```
A ?- t1 \/ t2
=========== DISJ1_TAC
A ?- t1
```

Failure

Fails if the goal is not a disjunction.

See also

DISJ1, DISJ2, DISJ2_TAC.

DISJ2

DISJ2 : (term \rightarrow thm \rightarrow thm)

Synopsis

Introduces a left disjunct into the conclusion of a theorem.

Description

A |- t2 ----- DISJ2 "t1" A |- t1 \/ t2

Failure

Fails if the term argument is not boolean.

Example

#DISJ2 "F" TRUTH;;
|- F \/ T

See also

DISJ1, DISJ1_TAC, DISJ2_TAC, DISJ_CASES.

DISJ2_TAC

DISJ2_TAC : tactic

disjuncts

Synopsis

Selects the right disjunct of a disjunctive goal.

Description

A ?- t1 \/ t2 ====== DISJ2_TAC A ?- t2

Failure

Fails if the goal is not a disjunction.

See also

DISJ1, DISJ1_TAC, DISJ2.

disjuncts

Compat.disjuncts : term -> term list

Synopsis

Iteratively breaks apart a disjunction.

Description

Found in the hol88 library. disjuncts $(--'t1 \setminus / ... \setminus / tn'--)$ returns [(--'t1'--), ..., (--'tn'-) The argument term may be any tree of disjunctions, it need not have the form $(--'t1 \setminus / (t2 \setminus / (A \text{ term that is not a disjunction is simply returned as the sole element of a list. Note that$

```
disjuncts(list_mk_disj([(--'t1'--),...,(--'tn'--)]))
```

will not return [(--'t1'--),...,(--'tn'--)] if any of t1,...,tn are disjunctions.

Failure

Never fails. Unless, of course, you have not loaded the hol88 library.

Example

```
- list_mk_disj [(--'a \/ b'--),(--'c \/ d'--),(--'e \/ f'--)];
(--'(a \/ b) \/ (c \/ d) \/ e \/ f'--) : term
- disjuncts it;
[(--'a'--),(--'b'--),(--'c'--),(--'d'--),(--'e'--),(--'f'--)] : term list
- list_mk_disj it;
(--'a \/ b \/ c \/ d \/ e \/ f'--) : term
- disjuncts (--'1'--);
[(--'1'--)] : term list
```

Comments

disjuncts is not in hol90. There, somewhat misleadingly, it is called strip_disj, in order to be consistent with all the other strip_ routines. Because disjuncts splits both the left and right sides of a disjunction, this operation is not the inverse of list_mk_disj. It may be useful to introduce list_dest_disj for splitting only the right tails of a disjunction.

See also

list_mk_disj, dest_disj.

DISJ_CASES

DISJ_CASES : (thm -> thm -> thm -> thm)

Synopsis

Eliminates disjunction by cases.

Description

The rule DISJ_CASES takes a disjunctive theorem, and two 'case' theorems, each with one of the disjuncts as a hypothesis while sharing alpha-equivalent conclusions. A new theorem is returned with the same conclusion as the 'case' theorems, and the union of all assumptions excepting the disjuncts.

A |- t1 \/ t2 A1 u {t1} |- t A2 u {t2} |- t ----- DISJ_CASES A u A1 u A2 |- t

Failure

Fails if the first argument is not a disjunctive theorem, or if the conclusions of the other two theorems are not alpha-convertible.

Example

Specializing the built-in theorem num_CASES gives the theorem:

th = $|-(m = 0) \setminus / (?n. m = SUC n)$

Using two additional theorems, each having one disjunct as a hypothesis:

th1 = (m = 0 | - (PRE m = m) = (m = 0))th2 = (?n. m = SUC n'' | - (PRE m = m) = (m = 0))

a new theorem can be derived:

#DISJ_CASES th th1 th2;; |- (PRE m = m) = (m = 0)

Comments

Neither of the 'case' theorems is required to have either disjunct as a hypothesis, but otherwise DISJ_CASES is pointless.

See also

DISJ_CASES_TAC, DISJ_CASES_THEN, DISJ_CASES_THEN2, DISJ_CASES_UNION, DISJ1, DISJ2.

DISJ_CASES_TAC

DISJ_CASES_TAC : thm_tactic

Synopsis

Produces a case split based on a disjunctive theorem.

Description

Given a theorem th of the form A \mid - u \setminus / v, DISJ_CASES_TAC th applied to a goal produces two subgoals, one with u as an assumption and one with v:

Failure

Fails if the given theorem does not have a disjunctive conclusion.

Example

Given the simple fact about arithmetic th, $|-(m = 0) \setminus / (?n. m = SUC n)$, the tactic DISJ_CASES_TAC th can be used to produce a case split:

```
#DISJ_CASES_TAC th ([],"(P:num -> bool) m");;
([(["m = 0"], "P m");
 (["?n. m = SUC n"], "P m")], -) : subgoals
```

Uses

Performing a case analysis according to a disjunctive theorem.

See also

ASSUME_TAC, ASM_CASES_TAC, COND_CASES_TAC, DISJ_CASES_THEN, STRUCT_CASES_TAC.

DISJ_CASES_THEN

DISJ_CASES_THEN : thm_tactical

Synopsis

Applies a theorem-tactic to each disjunct of a disjunctive theorem.

Description

If the theorem-tactic f:thm->tactic applied to either ASSUMEd disjunct produces results as follows when applied to a goal (A ?- t):

 A ?- t
 A ?- t

 =======
 f (u |- u)
 and
 =======
 f (v |- v)

 A ?- t1
 A ?- t2

then applying DISJ_CASES_THEN f ($|-u \rangle / v$) to the goal (A ?- t) produces two sub-

goals.

```
A ?- t
================= DISJ_CASES_THEN f (|- u \/ v)
A ?- t1 A ?- t2
```

Failure

Fails if the theorem is not a disjunction. An invalid tactic is produced if the theorem has any hypothesis which is not alpha-convertible to an assumption of the goal.

Example

Given the theorem

th = $|-(m = 0) \setminus / (?n. m = SUC n)$

and a goal of the form ?-(PRE m = m) = (m = 0), applying the tactic

DISJ_CASES_THEN ASSUME_TAC th

produces two subgoals, each with one disjunct as an added assumption:

?n. m = SUC n ?- (PRE m = m) = (m = 0) m = 0 ?- (PRE m = m) = (m = 0)

Uses

Building cases tactics. For example, DISJ_CASES_TAC could be defined by:

let DISJ_CASES_TAC = DISJ_CASES_THEN ASSUME_TAC

Comments

Use DISJ_CASES_THEN2 to apply different tactic generating functions to each case.

See also

STRIP_THM_THEN, CHOOSE_THEN, CONJUNCTS_THEN, CONJUNCTS_THEN2, DISJ_CASES_TAC, DISJ_CASES_THEN2, DISJ_CASES_THENL.

DISJ_CASES_THEN2

DISJ_CASES_THEN2 : (thm_tactic -> thm_tactical)

Synopsis

Applies separate theorem-tactics to the two disjuncts of a theorem.

Description

If the theorem-tactics f1 and f2, applied to the ASSUMEd left and right disjunct of a theorem $|-u \rangle / v$ respectively, produce results as follows when applied to a goal (A ?- t):

A ?- tA ?- t======f1 (u |- u)and======A ?- t1A ?- t2

then applying DISJ_CASES_THEN2 f1 f2 (|- u \/ v) to the goal (A ?- t) produces two subgoals.

A ?- t ================= DISJ_CASES_THEN2 f1 f2 (|- u \/ v) A ?- t1 A ?- t2

Failure

Fails if the theorem is not a disjunction. An invalid tactic is produced if the theorem has any hypothesis which is not alpha-convertible to an assumption of the goal.

Example

Given the theorem

th = $|-(m = 0) \setminus / (?n. m = SUC n)$

and a goal of the form ?-(PRE m = m) = (m = 0), applying the tactic

DISJ_CASES_THEN2 SUBST1_TAC ASSUME_TAC th

to the goal will produce two subgoals

?n. m = SUC n ?- (PRE m = m) = (m = 0)

?-(PRE 0 = 0) = (0 = 0)

The first subgoal has had the disjunct m = 0 used for a substitution, and the second has

added the disjunct to the assumption list. Alternatively, applying the tactic

```
DISJ_CASES_THEN2 SUBST1_TAC (CHOOSE_THEN SUBST1_TAC) th
```

to the goal produces the subgoals:

?- (PRE(SUC n) = SUC n) = (SUC n = 0)?- (PRE 0 = 0) = (0 = 0)

Uses

Building cases tacticals. For example, DISJ_CASES_THEN could be defined by:

```
let DISJ_CASES_THEN f = DISJ_CASES_THEN2 f f
```

See also

STRIP_THM_THEN, CHOOSE_THEN, CONJUNCTS_THEN, CONJUNCTS_THEN2, DISJ_CASES_THEN, DISJ_CASES_THENL.

DISJ_CASES_THENL

DISJ_CASES_THENL : (thm_tactic list -> thm_tactic)

Synopsis

Applies theorem-tactics in a list to the corresponding disjuncts in a theorem.

Description

If the theorem-tactics f1...fn applied to the ASSUMEd disjuncts of a theorem

|- d1 \/ d2 \/...\/ dn

produce results as follows when applied to a goal (A ?- t):

A ?- t A ?- t ======== f1 (d1 |- d1) and ... and ======= fn (dn |- dn) A ?- t1 A ?- tn

then applying DISJ_CASES_THENL [f1;...;fn] ($|-d1 \setminus ... \leq dn$) to the goal (A ?- t)

produces n subgoals.

```
A ?- t
================= DISJ_CASES_THENL [f1;...;fn] (|- d1 \/...\/ dn)
A ?- t1 ... A ?- tn
```

DISJ_CASES_THENL is defined using iteration, hence for theorems with more than n disjuncts, dn would itself be disjunctive.

Failure

Fails if the number of tactic generating functions in the list exceeds the number of disjuncts in the theorem. An invalid tactic is produced if the theorem has any hypothesis which is not alpha-convertible to an assumption of the goal.

Uses

Used when the goal is to be split into several cases, where a different tactic-generating function is to be applied to each case.

See also

```
CHOOSE_THEN, CONJUNCTS_THEN, CONJUNCTS_THEN2, DISJ_CASES_THEN, DISJ_CASES_THEN2, STRIP_THM_THEN.
```

DISJ_CASES_UNION

DISJ_CASES_UNION : (thm -> thm -> thm -> thm)

Synopsis

Makes an inference for each arm of a disjunct.

Description

Given a disjunctive theorem, and two additional theorems each having one disjunct as a hypothesis, a new theorem with a conclusion that is the disjunction of the conclusions of the last two theorems is produced. The hypotheses include the union of hypotheses of all three theorems less the two disjuncts.

A |- t1 \/ t2 A1 u {t1} |- t3 A2 u {t2} |- t4 ------ DISJ_CASES_UNION A u A1 u A2 |- t3 \/ t4

Failure

Fails if the first theorem is not a disjunction.

Example

The built-in theorem LESS_CASES can be specialized to:

th1 = $|-m < n \rangle / n \leq m$

and used with two additional theorems:

th2 = (m < n | - (m MOD n = m))th3 = $(\{0 < n, n <= m\} | - (m MOD n) = ((m - n) MOD n))$

to derive a new theorem:

#DISJ_CASES_UNION th1 th2 th3;; ["O < n"] |- (m MOD n = m) \setminus / (m MOD n = (m - n) MOD n)

See also DISJ_CASES_TAC, DISJ1, DISJ2.

DISJ_IMP

DISJ_IMP : (thm -> thm)

Synopsis

Converts a disjunctive theorem to an equivalent implicative theorem.

Description

The left disjunct of a disjunctive theorem becomes the negated antecedent of the newly generated theorem.

A |- t1 \/ t2 ----- DISJ_IMP A |- ~t1 ==> t2

Failure

Fails if the theorem is not a disjunction.

Example

Specializing the built-in theorem LESS_CASES gives the theorem:

th = $|-m < n \setminus / n <= m$

to which DISJ_IMP may be applied:

#DISJ_IMP th;; |- ~m < n ==> n <= m</pre>

See also

DISJ_CASES.

е

e : (tactic -> void)

Synopsis

Applies a tactic to the current goal, stacking the resulting subgoals.

Description

The function e is part of the subgoal package. It is an abbreviation for expand. For a description of the subgoal package, see set_goal.

Failure

As for expand.

Uses

Doing a step in an interactive goal-directed proof.

See also

```
b, backup, backup_limit, expand, expandf, g, get_state, p, print_state, r,
rotate, save_top_thm, set_goal, set_state, top_goal, top_thm, VALID.
```

el

```
el : (int -> * list -> *)
```

Synopsis

Extracts a specified element from a list.

Description

el i [x1;...;xn] returns xi. Note that the elements are numbered starting from 1, not 0.

Failure

Fails with el if the integer argument is less than 1 or greater than the length of the list.

Example

```
#el 3 [1;2;7;1];;
7 : int
```

See also

hd, tl.

empty_rewrites

empty_rewrites: rewrites

Synopsis

The empty database of rewrite rules.

Description Uses

to build other rewrite sets.

See also base_rewrites, add_base_rewrites, add_rewrites.

end_itlist

end_itlist : ((* -> * -> *) -> * list -> *)

Synopsis

List iteration function. Applies a binary function between adjacent elements of a list.

Description

end_itlist f [x1;...;xn] returns f x1 (... (f x(n-1) xn)...). Returns x for a one-element list [x].

Failure

Fails with end_itlist if list is empty.

Example

#end_itlist (\x y. x + y) [1;2;3;4];;
10 : int

See also

itlist, rev_itlist.

EQF_ELIM

EQF_ELIM : (thm -> thm)

Synopsis

Replaces equality with F by negation.

Description

A |- tm = F ----- EQF_ELIM A |- ~tm

Failure

Fails if the argument theorem is not of the form $A \mid -tm = F$.

See also

EQF_INTRO, EQT_ELIM, EQT_INTRO.

EQF_INTRO

EQF_INTRO : (thm -> thm)

Synopsis

Converts negation to equality with F.

Description

A |- ~tm ----- EQF_INTRO A |- tm = F

Failure

Fails if the argument theorem is not a negation.

See also EQF_ELIM, EQT_ELIM, EQT_INTRO.

EQT_ELIM

EQT_ELIM : (thm -> thm)

Synopsis

Eliminates equality with T.

Description

A |- tm = T ----- EQT_ELIM A |- tm

Failure

Fails if the argument theorem is not of the form $A \mid -tm = T$.

See also

EQT_INTRO, EQF_ELIM, EQF_INTRO.

EQT_INTRO

EQT_INTRO : (thm -> thm)

Synopsis

Introduces equality with T.

Description

A |- tm ----- EQF_INTRO A |- tm = T

Failure

Never fails.

See also

EQT_ELIM, EQF_ELIM, EQF_INTRO.

EQ_IMP_RULE

EQ_IMP_RULE : (thm -> (thm # thm))

Synopsis

Derives forward and backward implication from equality of boolean terms.

Description

When applied to a theorem A |-t1 = t2, where t1 and t2 both have type bool, the inference rule EQ_IMP_RULE returns the theorems A |-t1 => t2 and A |-t2 => t1.

A |- t1 = t2 ----- EQ_IMP_RULE A |- t1 ==> t2 A |- t2 ==> t1

Failure

Fails unless the conclusion of the given theorem is an equation between boolean terms.

See also

EQ_MP, EQ_TAC, IMP_ANTISYM_RULE.

EQ_MP

 EQ_MP : (thm -> thm -> thm)

Synopsis

Equality version of the Modus Ponens rule.

Description

When applied to theorems A1 |-t1 = t2 and A2 |-t1, the inference rule EQ_MP returns the theorem A1 u A2 |-t2.

A1 |- t1 = t2 A2 |- t1----- EQ_MP A1 u A2 |- t2

Failure

Fails unless the first theorem is equational and its left side is the same as the conclusion of the second theorem (and is therefore of type bool), up to alpha-conversion.

See also

EQ_IMP_RULE, IMP_ANTISYM_RULE, MP.

EQ_TAC

EQ_TAC : tactic

Synopsis

Reduces goal of equality of boolean terms to forward and backward implication.

Description

When applied to a goal A ?- t1 = t2, where t1 and t2 have type bool, the tactic EQ_TAC returns the subgoals A ?- t1 ==> t2 and A ?- t2 ==> t1.

Failure

Fails unless the conclusion of the goal is an equation between boolean terms.

See also

EQ_IMP_RULE, IMP_ANTISYM_RULE.

ETA_CONV

ETA_CONV : conv

Synopsis

Performs a toplevel eta-conversion.

Description

ETA_CONV maps an eta-redex "\x. t x", where x does not occur free in t, to the theorem |-(x. t x) = t.

Failure

Fails if the input term is not an eta-redex.

EVERY

EVERY : (tactic list -> tactic)

Synopsis

Sequentially applies all the tactics in a given list of tactics.

Description

When applied to a list of tactics [T1; ... ;Tn], and a goal g, the tactical EVERY applies each tactic in sequence to every subgoal generated by the previous one. This can be represented as:

EVERY [T1;...;Tn] = T1 THEN ... THEN Tn

If the tactic list is empty, the resulting tactic has no effect.

Failure

The application of EVERY to a tactic list never fails. The resulting tactic fails iff any of the component tactics do.

Comments

It is possible to use EVERY instead of THEN, but probably stylistically inferior. EVERY is more useful when applied to a list of tactics generated by a function.

See also

FIRST, MAP_EVERY, THEN.

EVERY_ASSUM

```
EVERY_ASSUM : (thm_tactic -> tactic)
```

Synopsis

Sequentially applies all tactics given by mapping a function over the assumptions of a goal.

Description

When applied to a theorem-tactic f and a goal ({A1;...;An} ?- C), the EVERY_ASSUM tactical maps f over a list of ASSUMEd assumptions then applies the resulting tactics, in sequence, to the goal:

```
EVERY_ASSUM f ({A1;...;An} ?- C)
= (f(A1 |- A1) THEN ... THEN f(An |- An)) ({A1;...;An} ?- C)
```

If the goal has no assumptions, then EVERY_ASSUM has no effect.

Failure

The application of EVERY_ASSUM to a theorem-tactic and a goal fails if the theorem-tactic fails when applied to any of the ASSUMEd assumptions of the goal, or if any of the resulting tactics fail when applied sequentially.

See also

ASSUM_LIST, MAP_EVERY, MAP_FIRST, THEN.

EVERY_CONJ_CONV

EVERY_CONJ_CONV : conv -> conv

Synopsis

Applies a conversion to every top-level conjunct in a term.

Description

The term EVERY_CONJ_CONV c t takes the conversion c and applies this to every top-level conjunct within term t. A top-level conjunct is a sub-term that can be reached from the root of the term by breaking apart only conjunctions. The terms affected by c are those that would be returned by a call to strip_conj c. In particular, if the term as a whole is not a conjunction, then the conversion will be applied to the whole term.

Failure

Fails if the conversion argument fails when applied to any of the top-level conjuncts in a term.

Example

- EVERY_CONJ_CONV BETA_CONV (Term'(\x. x /\ y) p');
- > val it = |-(x. x / y) p = p / y : Thm.thm
- EVERY_CONJ_CONV BETA_CONV (Term'(\y. y /\ p) q /\ (\z. z) r');
- > val it = |- (\y. y /\ p) q /\ (\z. z) r = (q /\ p) /\ r : Thm.thm

Uses

Useful for applying a conversion to all of the "significant" sub-terms within a term without having to worry about the exact structure of its conjunctive skeleton.

See also

EVERY_DISJ_CONV, RATOR_CONV, RAND_CONV, LAND_CONV

EVERY_CONV

EVERY_CONV : (conv list -> conv)

Applies in sequence all the conversions in a given list of conversions.

Description

EVERY_CONV [c1;...;cn] "t" returns the result of applying the conversions c1, ..., cn in sequence to the term "t". The conversions are applied in the order in which they are given in the list. In particular, if ci "ti" returns |- ti=ti+1 for i from 1 to n, then EVERY_CONV [c1;...;cn] "t1" returns |- t1=t(n+1). If the supplied list of conversions is empty, then EVERY_CONV returns the identity conversion. That is, EVERY_CONV [] "t" returns |- t=t.

Failure

EVERY_CONV [c1;...;cn] "t" fails if any one of the conversions c1, ..., cn fails when applied in sequence as specified above.

See also

THENC.

EVERY_DISJ_CONV

EVERY_DISJ_CONV : conv -> conv

Synopsis

Applies a conversion to every top-level disjunct in a term.

Description

The term EVERY_DISJ_CONV c t takes the conversion c and applies this to every top-level disjunct within term t. A top-level disjunct is a sub-term that can be reached from the root of the term by breaking apart only disjunctions. The terms affected by c are those that would be returned by a call to strip_disj c. In particular, if the term as a whole is not a disjunction, then the conversion will be applied to the whole term.

Failure

Fails if the conversion argument fails when applied to any of the top-level disjuncts in the term.

Example

Uses

Useful for applying a conversion to all of the "significant" sub-terms within a term without having to worry about the exact structure of its disjunctive skeleton.

See also

EVERY_CONJ_CONV, RATOR_CONV, RAND_CONV, LAND_CONV.

EVERY_TCL

EVERY_TCL : (thm_tactical list -> thm_tactical)

Synopsis

Composes a list of theorem-tacticals.

Description

When given a list of theorem-tacticals and a theorem, EVERY_TCL simply composes their effects on the theorem. The effect is:

EVERY_TCL [ttl1;...;ttln] = ttl1 THEN_TCL ... THEN_TCL ttln

In other words, if:

ttl1 ttac th1 = ttac th2 ... ttln ttac thn = ttac thn'

then:

EVERY_TCL [ttl1;...;ttln] ttac th1 = ttac thn'

If the theorem-tactical list is empty, the resulting theorem-tactical behaves in the same way as ALL_THEN, the identity theorem-tactical.

Failure

The application to a list of theorem-tacticals never fails.

See also

FIRST_TCL, ORELSE_TCL, REPEAT_TCL, THEN_TCL.

EXISTENCE

EXISTENCE : (thm -> thm)

Synopsis

Deduces existence from unique existence.

Description

When applied to a theorem with a unique-existentially quantified conclusion, EXISTENCE returns the same theorem with normal existential quantification over the same variable.

A |- ?!x. p ----- EXISTENCE A |- ?x. p

Failure

Fails unless the conclusion of the theorem is unique-existentially quantified.

See also

EXISTS_UNIQUE_CONV.

exists

exists : ((* -> bool) -> * list -> bool)

Synopsis

Tests a list to see if it has at least one element satisfying a predicate.

Description

exists p l applies p to the elements of l in order until one is found which satisfies p, or until the list is exhausted, returning true or false accordingly.

Failure

Never fails.

See also

forall, find, tryfind, mem, assoc, rev_assoc.

EXISTS

```
EXISTS : ((term # term) -> thm -> thm)
```

Synopsis

Introduces existential quantification given a particular witness.

Description

When applied to a pair of terms and a theorem, the first term an existentially quantified pattern indicating the desired form of the result, and the second a witness whose substitution for the quantified variable gives a term which is the same as the conclusion of the theorem, EXISTS gives the desired theorem.

```
A |- p[u/x]
----- EXISTS ("?x. p","u")
A |- ?x. p
```

Failure

Fails unless the substituted pattern is the same as the conclusion of the theorem.

Example

The following examples illustrate how it is possible to deduce different things from the same theorem:

```
#EXISTS ("?x. x=T", "T") (REFL "T");;
|- ?x. x = T
#EXISTS ("?x:bool. x=x", "T") (REFL "T");;
|- ?x. x = x
```

See also

CHOOSE, EXISTS_TAC.

EXISTS_AND_CONV

EXISTS_AND_CONV : conv

140

Moves an existential quantification inwards through a conjunction.

Description

When applied to a term of the form ?x. P /\ Q, where x is not free in both P and Q, EXISTS_AND_CONV returns a theorem of one of three forms, depending on occurrences of the variable x in P and Q. If x is free in P but not in Q, then the theorem:

|-(?x. P / Q) = (?x.P) / Q

is returned. If x is free in Q but not in P, then the result is:

|-(?x. P / Q) = P / (?x.Q)

And if x is free in neither P nor Q, then the result is:

|-(?x. P / Q) = (?x.P) / (?x.Q)

Failure

EXISTS_AND_CONV fails if it is applied to a term not of the form ?x. P /\ Q, or if it is applied to a term ?x. P /\ Q in which the variable x is free in both P and Q.

See also

AND_EXISTS_CONV, LEFT_AND_EXISTS_CONV, RIGHT_AND_EXISTS_CONV.

EXISTS_EQ

 $EXISTS_EQ$: (term -> thm -> thm)

Synopsis

Existentially quantifies both sides of an equational theorem.

Description

When applied to a variable x and a theorem whose conclusion is equational, $A \mid -t1 = t2$, the inference rule EXISTS_EQ returns the theorem $A \mid -(?x. t1) = (?x. t2)$, provided

the variable x is not free in any of the assumptions.

A |- t1 = t2 ------ EXISTS_EQ "x" [where x is not free in A] A |- (?x.t1) = (?x.t2)

Failure

Fails unless the theorem is equational with both sides having type bool, or if the term is not a variable, or if the variable to be quantified over is free in any of the assumptions.

See also

```
AP_TERM, EXISTS_IMP, FORALL_EQ, MK_EXISTS, SELECT_EQ.
```

EXISTS_IMP

EXISTS_IMP : (term -> thm -> thm)

Synopsis

Existentially quantifies both the antecedent and consequent of an implication.

Description

When applied to a variable x and a theorem A |-t1 => t2, the inference rule EXISTS_IMP returns the theorem A |-(?x. t1) => (?x. t2), provided x is not free in the assumptions.

A |- t1 ==> t2 ----- EXISTS_IMP "x" [where x is not free in A] A |- (?x.t1) ==> (?x.t2)

Failure

Fails if the theorem is not implicative, or if the term is not a variable, or if the term is a variable but is free in the assumption list.

See also

EXISTS_EQ.

EXISTS_IMP_CONV

EXISTS_IMP_CONV : conv

Moves an existential quantification inwards through an implication.

Description

When applied to a term of the form ?x. P ==> Q, where x is not free in both P and Q, EXISTS_IMP_CONV returns a theorem of one of three forms, depending on occurrences of the variable x in P and Q. If x is free in P but not in Q, then the theorem:

|-(?x. P ==> Q) = (!x.P) ==> Q

is returned. If x is free in Q but not in P, then the result is:

 $|-(?_{X}, P ==> Q) = P ==>(?_{X}, Q)$

And if x is free in neither P nor Q, then the result is:

|-(?x. P ==> Q) = (!x.P) ==> (?x.Q)

Failure

EXISTS_IMP_CONV fails if it is applied to a term not of the form ?x. P ==> Q, or if it is applied to a term ?x. P ==> Q in which the variable x is free in both P and Q.

See also

LEFT_IMP_FORALL_CONV, RIGHT_IMP_EXISTS_CONV.

EXISTS_NOT_CONV

EXISTS_NOT_CONV : conv

Synopsis

Moves an existential quantification inwards through a negation.

Description

When applied to a term of the form ?x.~P, the conversion EXISTS_NOT_CONV returns the theorem:

 $|-(?x.^{P}) = (!x. P)$

Failure

Fails if applied to a term not of the form ?x.~P.

See also

FORALL_NOT_CONV, NOT_EXISTS_CONV, NOT_FORALL_CONV.

EXISTS_OR_CONV

EXISTS_OR_CONV : conv

Synopsis

Moves an existential quantification inwards through a disjunction.

Description

When applied to a term of the form ?x. P / Q, the conversion EXISTS_OR_CONV returns the theorem:

 $|-(?x. P \setminus / Q) = (?x.P) \setminus / (?x.Q)$

Failure

Fails if applied to a term not of the form ?x. P / Q.

See also

```
OR_EXISTS_CONV, LEFT_OR_EXISTS_CONV, RIGHT_OR_EXISTS_CONV.
```

EXISTS_TAC

EXISTS_TAC : (term -> tactic)

Synopsis

Reduces existentially quantified goal to one involving a specific witness.

Description

When applied to a term u and a goal ?x. t, the tactic EXISTS_TAC reduces the goal to t[u/x] (substituting u for all free instances of x in t, with variable renaming if necessary

to avoid free variable capture).

```
A ?- ?x. t
========== EXISTS_TAC "u"
A ?- t[u/x]
```

Failure

Fails unless the goal's conclusion is existentially quantified and the term supplied has the same type as the quantified variable in the goal.

Example

The goal:

?- ?x. x=T

can be solved by:

EXISTS_TAC "T" THEN REFL_TAC

See also EXISTS.

EXISTS_UNIQUE_CONV

EXISTS_UNIQUE_CONV : conv

Synopsis

Expands with the definition of unique existence.

Description

Given a term of the form "?!x.P[x]", the conversion EXISTS_UNIQUE_CONV proves that this assertion is equivalent to the conjunction of two statements, namely that there exists at least one value x such that P[x], and that there is at most one value x for which P[x] holds. The theorem returned is:

|-(?! x. P[x]) = (?x. P[x]) / (!x x'. P[x] / P[x'] ==> (x = x'))

where x' is a primed variant of x that does not appear free in the input term. Note that the quantified variable x need not in fact appear free in the body of the input term. For

example, EXISTS_UNIQUE_CONV "?!x.T" returns the theorem:

|-(?! x. T) = (?x. T) / (!x x'. T / T ==> (x = x'))

Failure

EXISTS_UNIQUE_CONV tm fails if tm does not have the form "?!x.P".

See also EXISTENCE.

expand

expand : (tactic -> void)

Synopsis

Applies a tactic to the current goal, stacking the resulting subgoals.

Description

The function expand is part of the subgoal package. It may be abbreviated by the function e. It applies a tactic to the current goal to give a new proof state. The previous state is stored on the backup list. If the tactic produces subgoals, the new proof state is formed from the old one by removing the current goal from the goal stack and adding a new level consisting of its subgoals. The corresponding justification is placed on the justification stack. The new subgoals are printed. If more than one subgoal is produced, they are printed from the bottom of the stack so that the new current goal is printed last.

If a tactic solves the current goal (returns an empty subgoal list), then its justification is used to prove a corresponding theorem. This theorem is incorporated into the justification of the parent goal and printed. If the subgoal was the last subgoal of the level, the level is removed and the parent goal is proved using its (new) justification. This process is repeated until a level with unproven subgoals is reached. The next goal on the goal stack then becomes the current goal. This goal is printed. If all the subgoals are proved, the resulting proof state consists of the theorem proved by the justifications.

The tactic applied is a validating version of the tactic given. It ensures that the justification of the tactic does provide a proof of the goal from the subgoals generated by the tactic. It will cause failure if this is not so. The tactical VALID performs this validation.

For a description of the subgoal package, see set_goal.

Failure

expand tac fails if the tactic tac fails for the top goal. It will diverge if the tactic diverges for the goal. It will fail if there are no unproven goals. This could be because no goal has been set using set_goal or because the last goal set has been completely proved. It will also fail in cases when the tactic is invalid.

Example

```
#expand CONJ_TAC;;
OK..
evaluation failed
                      no goals to expand
#g "(HD[1;2;3] = 1) /\ (TL[1;2;3] = [2;3])";;
"(HD[1;2;3] = 1) /\ (TL[1;2;3] = [2;3])"
() : void
#expand CONJ_TAC;;
OK..
2 subgoals
"TL[1;2;3] = [2;3]"
"HD[1;2;3] = 1"
() : void
#expand (REWRITE_TAC[HD]);;
OK..
goal proved
|-HD[1;2;3] = 1
Previous subproof:
"TL[1;2;3] = [2;3]"
() : void
#expand (REWRITE_TAC[TL]);;
OK..
goal proved
|-TL[1;2;3] = [2;3]
|-(HD[1;2;3] = 1) / (TL[1;2;3] = [2;3])
Previous subproof:
goal proved
() : void
```

In the following example an invalid tactic is used. It is invalid because it assumes

something that is not on the assumption list of the goal. The justification adds this assumption to the assumption list so the justification would not prove the goal that was set.

```
#set_goal([],"1=2");;
"1 = 2"
() : void
#expand (REWRITE_TAC[ASSUME "1=2"]);;
OK..
evaluation failed Invalid tactic
```

Uses

Doing a step in an interactive goal-directed proof.

See also

```
b, backup, backup_limit, e, expandf, g, get_state, p, print_state, r, rotate,
save_top_thm, set_goal, set_state, top_goal, top_thm, VALID.
```

expandf

expandf : (tactic -> unit)

Synopsis

Applies a tactic to the current goal, stacking the resulting subgoals.

Description

The function expandf is a faster version of expand. It does not use a validated version of the tactic. That is, no check is made that the justification of the tactic does prove the goal from the subgoals it generates. If an invalid tactic is used, the theorem ultimately proved may not match the goal originally set. Alternatively, failure may occur when the justifications are applied in which case the theorem would not be proved. For a description of the subgoal package, see under set_goal.

Failure

Calling expandf tac fails if the tactic tac fails for the top goal. It will diverge if the tactic diverges for the goal. It will fail if there are no unproven goals. This could be because no goal has been set using set_goal or because the last goal set has been completely

proved. If an invalid tactic, whose justification actually fails, has been used earlier in the proof, expandf tac may succeed in applying tac and apparently prove the current goal. It may then fail as it applies the justifications of the tactics applied earlier.

Example

```
- g 'HD[1;2;3] = 1';
'HD[1;2;3] = 1'
() : void
- expandf (REWRITE_TAC[HD;TL]);;
OK..
goal proved
|- HD[1;2;3] = 1
Previous subproof:
goal proved
() : void
```

The following example shows how the use of an invalid tactic can yield a theorem which does not correspond to the goal set.

```
- set_goal([], Term '1=2');
'1 = 2'
() : void
- expandf (REWRITE_TAC[ASSUME (Term'1=2')]);
OK..
goal proved
. |- 1 = 2
Previous subproof:
goal proved
() : void
```

The proof assumed something which was not on the assumption list. This assumption appears in the assumption list of the theorem proved, even though it was not in the goal. An attempt to perform the proof using expand fails. The validated version of the tactic detects that the justification produces a theorem which does not correspond to the goal set. It therefore fails.

Uses

Saving CPU time when doing goal-directed proofs, since the extra validation is not done.

Redoing proofs quickly that are already known to work.

Comments

The CPU time saved may cause misery later. If an invalid tactic is used, this will only be discovered when the proof has apparently been finished and the justifications are applied.

```

EXT

EXT : (thm \rightarrow thm)

Synopsis

Derives equality of functions from extentional equivalence.

Description

When applied to a theorem A |-!x.t1 x = t2 x, the inference rule EXT returns the theorem A |-t1 = t2.

 $A \mid - !x. t1 x = t2 x$ ----- EXT [where x is not free in t1 or t2] $A \mid - t1 = t2$

Failure

Fails if the theorem does not have the form indicated above, or if the variable x is free either of the functions t1 or t2.

See also

AP_THM, ETA_CONV, FUN_EQ_CONV.

FAIL_TAC

FAIL_TAC : (string -> tactic)

150

filter

Synopsis

Tactic which always fails, with the supplied string.

Description

Whatever goal it is applied to, FAIL_TAC s always fails with the string s.

Failure

The application of FAIL_TAC to a string never fails; the resulting tactic always fails.

Example

The following example uses the fact that if a tactic t1 solves a goal, then the tactic t1 THEN t2 never results in the application of t2 to anything, because t1 produces no subgoals. In attempting to solve the following goal:

?- x => T | T

the tactic

```
REWRITE_TAC[] THEN FAIL_TAC 'Simple rewriting failed to solve goal'
```

will fail with the message provided, whereas:

CONV_TAC COND_CONV THEN FAIL_TAC 'Using COND_CONV failed to solve goal'

will silently solve the goal because COND_CONV reduces it to just ?- T.

See also All_TAC, NO_TAC.

filter

filter : ((* -> bool) -> * list -> * list)

Synopsis

Filters a list to the sublist of elements satisfying a predicate.

Description

filter p l applies p to every element of l, returning a list of those that satisfy p, in the order they appeared in the original list.

Failure

Never fails.

See also

mapfilter, partition, remove.

FILTER_ASM_REWRITE_RULE

```
FILTER_ASM_REWRITE_RULE : ((term -> bool) -> thm list -> thm -> thm)
```

Synopsis

Rewrites a theorem including built-in rewrites and some of the theorem's assumptions.

Description

This function implements selective rewriting with a subset of the assumptions of the theorem. The first argument (a predicate on terms) is applied to all assumptions, and the ones which return true are used (along with the set of basic tautologies and the given theorem list) to rewrite the theorem. See GEN_REWRITE_RULE for more information on rewriting.

Failure

FILTER_ASM_REWRITE_RULE does not fail. Using FILTER_ASM_REWRITE_RULE may result in a diverging sequence of rewrites. In such cases FILTER_ONCE_ASM_REWRITE_RULE may be used.

Uses

This rule can be applied when rewriting with all assumptions results in divergence. Typically, the predicate can model checks as to whether a certain variable appears on the left-hand side of an equational assumption, or whether the assumption is in disjunctive form.

Another use is to improve performance when there are many assumptions which are not applicable. Rewriting, though a powerful method of proving theorems in HOL, can result in a reduced performance due to the pattern matching and the number of primitive inferences involved.

See also

ASM_REWRITE_RULE, FILTER_ONCE_ASM_REWRITE_RULE, FILTER_PURE_ASM_REWRITE_RULE, FILTER_PURE_ONCE_ASM_REWRITE_RULE, GEN_REWRITE_RULE, ONCE_REWRITE_RULE, PURE_REWRITE_RULE, REWRITE_RULE.

FILTER_ASM_REWRITE_TAC

FILTER_ASM_REWRITE_TAC : ((term -> bool) -> thm list -> tactic)

Synopsis

Rewrites a goal including built-in rewrites and some of the goal's assumptions.

Description

This function implements selective rewriting with a subset of the assumptions of the goal. The first argument (a predicate on terms) is applied to all assumptions, and the ones which return true are used (along with the set of basic tautologies and the given theorem list) to rewrite the goal. See GEN_REWRITE_TAC for more information on rewriting.

Failure

FILTER_ASM_REWRITE_TAC does not fail, but it can result in an invalid tactic if the rewrite is invalid. This happens when a theorem used for rewriting has assumptions which are not alpha-convertible to assumptions of the goal. Using FILTER_ASM_REWRITE_TAC may result in a diverging sequence of rewrites. In such cases FILTER_ONCE_ASM_REWRITE_TAC may be used.

Uses

This tactic can be applied when rewriting with all assumptions results in divergence, or in an unwanted proof state. Typically, the predicate can model checks as to whether a certain variable appears on the left-hand side of an equational assumption, or whether the assumption is in disjunctive form. Thus it allows choice of assumptions to rewrite with in a position-independent fashion.

Another use is to improve performance when there are many assumptions which are not applicable. Rewriting, though a powerful method of proving theorems in HOL, can result in a reduced performance due to the pattern matching and the number of primitive inferences involved.

See also

```
ASM_REWRITE_TAC, FILTER_ONCE_ASM_REWRITE_TAC, FILTER_PURE_ASM_REWRITE_TAC, FILTER_PURE_ONCE_ASM_REWRITE_TAC, GEN_REWRITE_TAC, ONCE_REWRITE_TAC, PURE_REWRITE_TAC, REWRITE_TAC.
```

FILTER_DISCH_TAC

```
FILTER_DISCH_TAC : (term -> tactic)
```

Synopsis

Conditionally moves the antecedent of an implicative goal into the assumptions.

Description

FILTER_DISCH_TAC will move the antecedent of an implication into the assumptions, provided its parameter does not occur in the antecedent.

```
A ?- u ==> v
========== FILTER_DISCH_TAC "w"
A u {u} ?- v
```

Note that DISCH_TAC treats "~u" as "u ==> F". Unlike DISCH_TAC, the antecedent will be STRIPed into its various components before being ASSUMEd. This stripping includes generating multiple goals for case-analysis of disjunctions. Also, unlike DISCH_TAC, should any component of the discharged antecedent directly imply or contradict the goal, then this simplification will also be made. Again, unlike DISCH_TAC, FILTER_DISCH_TAC will not duplicate identical or alpha-equivalent assumptions.

Failure

FILTER_DISCH_TAC will fail if a term which is identical, or alpha-equivalent to "w" occurs free in the antecedent, or if the theorem is not an implication or a negation.

Comments

FILTER_DISCH_TAC "w" behaves like FILTER_DISCH_THEN STRIP_ASSUME_TAC "w".

See also

DISCH, DISCH_ALL, DISCH_TAC, DISCH_THEN, FILTER_DISCH_THEN, NEG_DISCH, STRIP_TAC, UNDISCH, UNDISCH_ALL, UNDISCH_TAC.

FILTER_DISCH_THEN

Conditionally gives to a theorem-tactic the antecedent of an implicative goal.

Description

If FILTER_DISCH_THEN's second argument, a term, does not occur in the antecedent, then FILTER_DISCH_THEN removes the antecedent and then creates a theorem by ASSUMEing it. This new theorem is passed to FILTER_DISCH_THEN's first argument, which is subsequently expanded. For example, if

```
A ?- t
======= f (ASSUME "u")
B ?- v
```

then

A ?- u ==> t ========== FILTER_DISCH_THEN f B ?- v

Note that FILTER_DISCH_THEN treats "~u" as "u ==> F".

Failure

FILTER_DISCH_THEN will fail if a term which is identical, or alpha-equivalent to "w" occurs free in the antecedent. FILTER_DISCH_THEN will also fail if the theorem is an implication or a negation.

Comments

FILTER_DISCH_THEN is most easily understood by first understanding DISCH_THEN.

Uses

For preprocessing an antecedent before moving it to the assumptions, or for using antecedents and then throwing them away.

See also

DISCH, DISCH_ALL, DISCH_TAC, DISCH_THEN, FILTER_DISCH_TAC, NEG_DISCH, STRIP_TAC, UNDISCH, UNDISCH_ALL, UNDISCH_TAC.

FILTER_GEN_TAC

FILTER_GEN_TAC : (term -> tactic)

Strips off a universal quantifier, but fails for a given quantified variable.

Description

When applied to a term s and a goal A ?- !x. t, the tactic FILTER_GEN_TAC fails if the quantified variable x is the same as s, but otherwise advances the goal in the same way as GEN_TAC, i.e. returns the goal A ?- t[x'/x] where x' is a variant of x chosen to avoid clashing with any variables free in the goal's assumption list. Normally x' is just x.

```
A ?- !x. t
=========== FILTER_GEN_TAC "s"
A ?- t[x'/x]
```

Failure

Fails if the goal's conclusion is not universally quantified or the quantified variable is equal to the given term.

See also

GEN, GEN_TAC, GENL, GEN_ALL, SPEC, SPECL, SPEC_ALL, SPEC_TAC, STRIP_TAC.

FILTER_ONCE_ASM_REWRITE_RULE

FILTER_ONCE_ASM_REWRITE_RULE : ((term -> bool) -> thm list -> thm -> thm)

Synopsis

Rewrites a theorem once including built-in rewrites and some of its assumptions.

Description

The first argument is a predicate applied to the assumptions. The theorem is rewritten with the assumptions for which the predicate returns true, the given list of theorems, and the tautologies stored in basic_rewrites. It searches the term of the theorem once, without applying rewrites recursively. Thus it avoids the divergence which can result from the application of FILTER_ASM_REWRITE_RULE. For more information on rewriting rules, see GEN_REWRITE_RULE.

Failure

Never fails.

156

Uses

This function is useful when rewriting with a subset of assumptions of a theorem, allowing control of the number of rewriting passes.

See also

ASM_REWRITE_RULE, FILTER_ASM_REWRITE_RULE, FILTER_PURE_ASM_REWRITE_RULE, FILTER_PURE_ONCE_ASM_REWRITE_RULE, GEN_REWRITE_RULE, ONCE_ASM_REWRITE_RULE, ONCE_DEPTH_CONV, PURE_ASM_REWRITE_RULE, PURE_ONCE_ASM_REWRITE_RULE, PURE_REWRITE_RULE, REWRITE_RULE.

FILTER_ONCE_ASM_REWRITE_TAC

FILTER_ONCE_ASM_REWRITE_TAC : ((term -> bool) -> thm list -> tactic)

Synopsis

Rewrites a goal once including built-in rewrites and some of its assumptions.

Description

The first argument is a predicate applied to the assumptions. The goal is rewritten with the assumptions for which the predicate returns true, the given list of theorems, and the tautologies stored in basic_rewrites. It searches the term of the goal once, without applying rewrites recursively. Thus it avoids the divergence which can result from the application of FILTER_ASM_REWRITE_TAC. For more information on rewriting tactics, see GEN_REWRITE_TAC.

Failure

Never fails.

Uses

This function is useful when rewriting with a subset of assumptions of a goal, allowing control of the number of rewriting passes.

See also

ASM_REWRITE_TAC, FILTER_ASM_REWRITE_TAC, FILTER_PURE_ASM_REWRITE_TAC, FILTER_PURE_ONCE_ASM_REWRITE_TAC, GEN_REWRITE_TAC, ONCE_ASM_REWRITE_TAC, ONCE_DEPTH_CONV, PURE_ASM_REWRITE_TAC, PURE_ONCE_ASM_REWRITE_TAC, PURE_REWRITE_TAC, REWRITE_TAC.

FILTER_PURE_ASM_REWRITE_RULE

FILTER_PURE_ASM_REWRITE_RULE : ((term -> bool) -> thm list -> thm ->thm)

Synopsis

Rewrites a theorem with some of the theorem's assumptions.

Description

This function implements selective rewriting with a subset of the assumptions of the theorem. The first argument (a predicate on terms) is applied to all assumptions, and the ones which return true are used to rewrite the goal. See GEN_REWRITE_RULE for more information on rewriting.

Failure

FILTER_PURE_ASM_REWRITE_RULE does not fail. Using FILTER_PURE_ASM_REWRITE_RULE may result in a diverging sequence of rewrites. In such cases FILTER_PURE_ONCE_ASM_REWRITE_RULE may be used.

Uses

This rule can be applied when rewriting with all assumptions results in divergence. Typically, the predicate can model checks as to whether a certain variable appears on the left-hand side of an equational assumption, or whether the assumption is in disjunctive form.

Another use is to improve performance when there are many assumptions which are not applicable. Rewriting, though a powerful method of proving theorems in HOL, can result in a reduced performance due to the pattern matching and the number of primitive inferences involved.

See also

ASM_REWRITE_RULE, FILTER_ASM_REWRITE_RULE, FILTER_ONCE_ASM_REWRITE_RULE, FILTER_PURE_ONCE_ASM_REWRITE_RULE, GEN_REWRITE_RULE, ONCE_REWRITE_RULE, PURE_REWRITE_RULE, REWRITE_RULE.

FILTER_PURE_ASM_REWRITE_TAC

FILTER_PURE_ASM_REWRITE_TAC : ((term -> bool) -> thm list -> tactic)

Rewrites a goal with some of the goal's assumptions.

Description

This function implements selective rewriting with a subset of the assumptions of the goal. The first argument (a predicate on terms) is applied to all assumptions, and the ones which return true are used to rewrite the goal. See GEN_REWRITE_TAC for more information on rewriting.

Failure

FILTER_PURE_ASM_REWRITE_TAC does not fail, but it can result in an invalid tactic if the rewrite is invalid. This happens when a theorem used for rewriting has assumptions which are not alpha-convertible to assumptions of the goal. Using FILTER_PURE_ASM_REWRITE_TAC may result in a diverging sequence of rewrites. In such cases FILTER_PURE_ONCE_ASM_REWRITE_TAC may be used.

Uses

This tactic can be applied when rewriting with all assumptions results in divergence, or in an unwanted proof state. Typically, the predicate can model checks as to whether a certain variable appears on the left-hand side of an equational assumption, or whether the assumption is in disjunctive form. Thus it allows choice of assumptions to rewrite with in a position-independent fashion.

Another use is to improve performance when there are many assumptions which are not applicable. Rewriting, though a powerful method of proving theorems in HOL, can result in a reduced performance due to the pattern matching and the number of primitive inferences involved.

See also

ASM_REWRITE_TAC, FILTER_ASM_REWRITE_TAC, FILTER_ONCE_ASM_REWRITE_TAC, FILTER_PURE_ONCE_ASM_REWRITE_TAC, GEN_REWRITE_TAC, ONCE_REWRITE_TAC, PURE_REWRITE_TAC, REWRITE_TAC.

FILTER_PURE_ONCE_ASM_REWRITE_RULE

FILTER_PURE_ONCE_ASM_REWRITE_RULE : ((term -> bool) -> thm list -> thm -> thm)

Synopsis

Rewrites a theorem once using some of its assumptions.

Description

The first argument is a predicate applied to the assumptions. The theorem is rewritten with the assumptions for which the predicate returns true and the given list of theorems. It searches the term of the theorem once, without applying rewrites recursively. Thus it avoids the divergence which can result from the application of FILTER_PURE_ASM_REWRITE_RULE. For more information on rewriting rules, see GEN_REWRITE_RULE.

Failure

Never fails.

Uses

This function is useful when rewriting with a subset of assumptions of a theorem, allowing control of the number of rewriting passes.

See also

ASM_REWRITE_RULE, FILTER_ASM_REWRITE_RULE, FILTER_ONCE_ASM_REWRITE_RULE, FILTER_PURE_ASM_REWRITE_RULE, GEN_REWRITE_RULE, ONCE_ASM_REWRITE_RULE, ONCE_DEPTH_CONV, PURE_ASM_REWRITE_RULE, PURE_ONCE_ASM_REWRITE_RULE, PURE_REWRITE_RULE, REWRITE_RULE.

FILTER_PURE_ONCE_ASM_REWRITE_TAC

FILTER_PURE_ONCE_ASM_REWRITE_TAC : ((term -> bool) -> thm list -> tactic)

Synopsis

Rewrites a goal once using some of its assumptions.

Description

The first argument is a predicate applied to the assumptions. The goal is rewritten with the assumptions for which the predicate returns true and the given list of theorems. It searches the term of the goal once, without applying rewrites recursively. Thus it avoids the divergence which can result from the application of FILTER_PURE_ASM_REWRITE_TAC. For more information on rewriting tactics, see GEN_REWRITE_TAC.

Failure

Never fails.

Uses

This function is useful when rewriting with a subset of assumptions of a goal, allowing control of the number of rewriting passes.

160

See also

ASM_REWRITE_TAC, FILTER_ASM_REWRITE_TAC, FILTER_ONCE_ASM_REWRITE_TAC, FILTER_PURE_ASM_REWRITE_TAC, GEN_REWRITE_TAC, ONCE_ASM_REWRITE_TAC, ONCE_DEPTH_CONV, PURE_ASM_REWRITE_TAC, PURE_ONCE_ASM_REWRITE_TAC, PURE_REWRITE_TAC, REWRITE_TAC.

FILTER_STRIP_TAC

FILTER_STRIP_TAC : (term -> tactic)

Synopsis

Conditionally strips apart a goal by eliminating the outermost connective.

Description

Stripping apart a goal in a more careful way than is done by STRIP_TAC may be necessary when dealing with quantified terms and implications. FILTER_STRIP_TAC behaves like STRIP_TAC, but it does not strip apart a goal if it contains a given term.

If u is a term, then FILTER_STRIP_TAC u is a tactic that removes one outermost occurrence of one of the connectives !, ==>, ~ or /\ from the conclusion of the goal t, provided the term being stripped does not contain u. A negation ~t is treated as the implication t ==> F. FILTER_STRIP_TAC u also breaks apart conjunctions without applying any filtering.

If t is a universally quantified term, FILTER_STRIP_TAC u strips off the quantifier:

where x' is a primed variant that does not appear free in the assumptions A. If t is a conjunction, no filtering is done and FILTER_STRIP_TAC u simply splits the conjunction:

A ?- v /\ w ============ FILTER_STRIP_TAC "u" A ?- v A ?- w

If t is an implication and the antecedent does not contain a free instance of u, then FILTER_STRIP_TAC u moves the antecedent into the assumptions and recursively splits

the antecedent according to the following rules (see STRIP_ASSUME_TAC):

where x' is a variant of x.

Failure

FILTER_STRIP_TAC u (A,t) fails if t is not a universally quantified term, an implication, a negation or a conjunction; or if the term being stripped contains u in the sense described above (conjunction excluded).

Example

When trying to solve the goal

?- !n. m <= n /\ n <= m ==> (m = n)

the universally quantified variable n can be stripped off by using

FILTER_STRIP_TAC "m:num"

and then the implication can be stripped apart by using

FILTER_STRIP_TAC "m:num = n"

Uses

FILTER_STRIP_TAC is used when stripping outer connectives from a goal in a more delicate way than STRIP_TAC. A typical application is to keep stripping by using the tactic REPEAT (FILTER_STRIP_TAC u) until one hits the term u at which stripping is to stop.

See also

CONJ_TAC, FILTER_DISCH_TAC, FILTER_DISCH_THEN, FILTER_GEN_TAC, STRIP_ASSUME_TAC, STRIP_TAC.

FILTER_STRIP_THEN

FILTER_STRIP_THEN : (thm_tactic -> term -> tactic)

Conditionally strips a goal, handing an antecedent to the theorem-tactic.

Description

Given a theorem-tactic ttac, a term u and a goal (A,t), FILTER_STRIP_THEN ttac u removes one outer connective (!, ==>, or ~) from t, if the term being stripped does not contain a free instance of u. A negation ~t is treated as the implication t ==> F. The theorem-tactic ttac is applied only when stripping an implication, by using the antecedent stripped off. FILTER_STRIP_THEN also breaks conjunctions.

FILTER_STRIP_THEN behaves like STRIP_GOAL_THEN, if the term being stripped does not contain a free instance of u. In particular, FILTER_STRIP_THEN STRIP_ASSUME_TAC behaves like FILTER_STRIP_TAC.

Failure

FILTER_STRIP_THEN ttac u (A,t) fails if t is not a universally quantified term, an implication, a negation or a conjunction; or if the term being stripped contains the term u (conjunction excluded); or if the application of ttac fails, after stripping the goal.

Example

When solving the goal

 $(n = 1) \implies (n * n = n)$

the application of FILTER_STRIP_THEN SUBST1_TAC "m:num" results in the goal

?-1 * 1 = 1

Uses

FILTER_STRIP_THEN is used when manipulating intermediate results using theorem-tactics, after stripping outer connectives from a goal in a more delicate way than STRIP_GOAL_THEN.

See also

CONJ_TAC, FILTER_DISCH_TAC, FILTER_DISCH_THEN, FILTER_GEN_TAC, FILTER_STRIP_TAC, STRIP_ASSUME_TAC, STRIP_GOAL_THEN.

find

Compat.find : ('a -> bool) -> 'a list -> 'a

find

Returns the first element of a list which satisfies a predicate.

Description

Found in the hol88 library. find p [x1;...;xn] returns the first xi in the list such that (p xi) is true.

Failure

Fails with find if no element satisfies the predicate. This will always be the case if the list is empty.

Comments

find is in Compat, because is is not found in hol90 (Lib.first is equivalent and is used instead).

See also

```
tryfind, mem, exists, forall, assoc, rev_assoc.
```

FIRST

```
FIRST : (tactic list -> tactic)
```

Synopsis

Applies the first tactic in a tactic list which succeeds.

Description

When applied to a list of tactics [T1;...;Tn], and a goal g, the tactical FIRST tries applying the tactics to the goal until one succeeds. If the first tactic which succeeds is Tm, then the effect is the same as just Tm. Thus FIRST effectively behaves as follows:

FIRST [T1;...;Tn] = T1 ORELSE ... ORELSE Tn

Failure

The application of FIRST to a tactic list never fails. The resulting tactic fails iff all the component tactics do when applied to the goal, or if the tactic list is empty.

See also

EVERY, ORELSE.

164

FIRST_ASSUM

FIRST_ASSUM : (thm_tactic -> tactic)

Synopsis

Maps a theorem-tactic over the assumptions, applying first successful tactic.

Description

The tactic

FIRST_ASSUM ttac ([A1; ...; An], g)

has the effect of applying the first tactic which can be produced by ttac from the ASSUMEd assumptions (A1 |- A1), ..., (An |- An) and which succeeds when applied to the goal. Failures of ttac to produce a tactic are ignored.

Failure

Fails if ttac (Ai |- Ai) fails for every assumption Ai, or if the assumption list is empty, or if all the tactics produced by ttac fail when applied to the goal.

Example

The tactic

FIRST_ASSUM (\asm. CONTR_TAC asm ORELSE ACCEPT_TAC asm)

searches the assumptions for either a contradiction or the desired conclusion. The tactic

FIRST_ASSUM MATCH_MP_TAC

searches the assumption list for an implication whose conclusion matches the goal, reducing the goal to the antecedent of the corresponding instance of this implication.

See also

ASSUM_LIST, EVERY, EVERY_ASSUM, FIRST, MAP_EVERY, MAP_FIRST.

FIRST_CONV

FIRST_CONV : (conv list -> conv)

Apply the first of the conversions in a given list that succeeds.

Description

FIRST_CONV [c1;...;cn] "t" returns the result of applying to the term "t" the first conversion ci that succeeds when applied to "t". The conversions are tried in the order in which they are given in the list.

Failure

FIRST_CONV [c1;...;cn] "t" fails if all the conversions c1, ..., cn fail when applied to the term "t". FIRST_CONV cs "t" also fails if cs is the empty list.

See also

ORELSEC.

FIRST_TCL

```
FIRST_TCL : (thm_tactical list -> thm_tactical)
```

Synopsis

Applies the first theorem-tactical in a list which succeeds.

Description

When applied to a list of theorem-tacticals, a theorem-tactic and a theorem, FIRST_TCL returns the tactic resulting from the application of the first theorem-tactical to the theorem-tactic and theorem which succeeds. The effect is the same as:

FIRST_TCL [ttl1;...;ttln] = ttl1 ORELSE_TCL ... ORELSE_TCL ttln

Failure

FIRST_TCL fails iff each tactic in the list fails when applied to the theorem-tactic and theorem. This is trivially the case if the list is empty.

See also

EVERY_TCL, ORELSE_TCL, REPEAT_TCL, THEN_TCL.

FIRST_X_ASSUM

Tactical.FIRST_X_ASSUM : thm_tactic -> tactic

166

Maps a theorem-tactic over the assumptions, applying first successful tactic and removing the assumption that gave rise to the successful tactic.

Description

The tactic

```
FIRST_X_ASSUM ttac ([A1; ...; An], g)
```

has the effect of applying the first tactic which can be produced by ttac from the ASSUMEd assumptions (A1 |- A1), ..., (An |- An) and which succeeds when applied to the goal. The assumption which produced the successful theorem-tactic is removed from the assumption list (before ttac is applied). Failures of ttac to produce a tactic are ignored.

Failure

Fails if ttac (Ai |- Ai) fails for every assumption Ai, or if the assumption list is empty, or if all the tactics produced by ttac fail when applied to the goal.

Example

The tactic

FIRST_X_ASSUM SUBST_ALL_TAC

searches the assumptions for an equality and causes its right hand side to be substituted for its left hand side throughout the goal and assumptions. It also removes the equality from the assumption list. Using FIRST_ASSUM above would leave an equality on the assumption list of the form x = x. The tactic

FIRST_X_ASSUM MATCH_MP_TAC

searches the assumption list for an implication whose conclusion matches the goal, reducing the goal to the antecedent of the corresponding instance of this implication and removing the implication from the assumption list.

Comments

The "X" in the name of this tactic is a mnemonic for the "crossing out" or removal of the assumption found.

See also

```
ASSUM_LIST, EVERY, PAT_ASSUM, EVERY_ASSUM, FIRST, MAP_EVERY, MAP_FIRST, UNDISCH_THEN.
```

FORALL_AND_CONV

FORALL_AND_CONV : conv

Synopsis

Moves a universal quantification inwards through a conjunction.

Description

When applied to a term of the form !x. P /\ Q, the conversion FORALL_AND_CONV returns the theorem:

|-(!x. P / Q) = (!x.P) / (!x.Q)

Failure

Fails if applied to a term not of the form !x. P / Q.

See also

AND_FORALL_CONV, LEFT_AND_FORALL_CONV, RIGHT_AND_FORALL_CONV.

FORALL_EQ

FORALL_EQ : (term -> thm -> thm)

Synopsis

Universally quantifies both sides of an equational theorem.

Description

When applied to a variable x and a theorem $A \mid -t1 = t2$, whose conclusion is an equation between boolean terms, FORALL_EQ returns the theorem $A \mid -(!x. t1) = (!x. t2)$, unless the variable x is free in any of the assumptions.

A |- t1 = t2 ----- FORALL_EQ "x" [where x is not free in A] A |- (!x.t1) = (!x.t2)

Failure

Fails if the theorem is not an equation between boolean terms, or if the supplied term is not simply a variable, or if the variable is free in any of the assumptions.

See also

AP_TERM, EXISTS_EQ, SELECT_EQ.

FORALL_IMP_CONV

FORALL_IMP_CONV : conv

Synopsis

Moves a universal quantification inwards through an implication.

Description

When applied to a term of the form !x. P ==> Q, where x is not free in both P and Q, FORALL_IMP_CONV returns a theorem of one of three forms, depending on occurrences of the variable x in P and Q. If x is free in P but not in Q, then the theorem:

|-(!x. P ==> Q) = (?x.P) ==> Q

is returned. If x is free in Q but not in P, then the result is:

|-(!x. P ==> Q) = P ==> (!x.Q)

And if x is free in neither P nor Q, then the result is:

|-(!x. P ==> Q) = (?x.P) ==> (!x.Q)

Failure

FORALL_IMP_CONV fails if it is applied to a term not of the form !x. P ==> Q, or if it is applied to a term !x. P ==> Q in which the variable x is free in both P and Q.

See also

LEFT_IMP_EXISTS_CONV, RIGHT_IMP_FORALL_CONV.

FORALL_NOT_CONV

FORALL_NOT_CONV : conv

Synopsis

Moves a universal quantification inwards through a negation.

Description

When applied to a term of the form !x.~P, the conversion FORALL_NOT_CONV returns the theorem:

 $|-(!x.^{P}) = (?x.^{P})$

Failure

Fails if applied to a term not of the form !x.~P.

See also

EXISTS_NOT_CONV, NOT_EXISTS_CONV, NOT_FORALL_CONV.

FORALL_OR_CONV

FORALL_OR_CONV : conv

Synopsis

Moves a universal quantification inwards through a disjunction.

Description

When applied to a term of the form $!x. P \lor Q$, where x is not free in both P and Q, FORALL_OR_CONV returns a theorem of one of three forms, depending on occurrences of the variable x in P and Q. If x is free in P but not in Q, then the theorem:

 $|-(!x. P \setminus / Q) = (!x.P) \setminus / Q$

is returned. If x is free in Q but not in P, then the result is:

 $|-(!x. P \setminus / Q) = P \setminus / (!x.Q)$

And if x is free in neither P nor Q, then the result is:

 $|-(!x. P \setminus / Q) = (!x.P) \setminus / (!x.Q)$

Failure

FORALL_OR_CONV fails if it is applied to a term not of the form $!x. P \setminus Q$, or if it is applied to a term $!x. P \setminus Q$ in which the variable x is free in both P and Q.

See also

OR_FORALL_CONV, LEFT_OR_FORALL_CONV, RIGHT_OR_FORALL_CONV.

170

FORK_CONV

FORK_CONV : (conv * conv) -> conv

Synopsis

Applies a pair of conversions to the arguments of a binary operator.

Description

If the conversion c1 maps a term t1 to the theorem |-t1 = t1', and the conversion c2 maps t2 to |-t2 = t2', then the conversion FORK_CONV (c1,c2) maps terms of the form f t1 t2 to theorems of the form |-ft1 t2 = ft1' t2'.

Failure

FORK_CONV (c1,c2) t will fail if t is not of the general form f t1 t2, or if c1 fails when applied to t1, or if c2 fails when applied to t2, or if c1 or c2 aren't really conversions, and thereby fail to return appropriate equational theorems.

Example

```
- FORK_CONV (BETA_CONV,REDUCE_CONV) (Term'(\x. x + 1)y * (10 DIV 3)');
> val it = |- (\x. x + 1) y * (10 DIV 3) = (y + 1) * 3 : Thm.thm
```

See also

BINOP_CONV, LAND_CONV, RAND_CONV, RATOR_CONV.

frees

hol88Lib.frees : term -> term list

Synopsis

Returns a list of the variables which are free in a term.

Description

Found in the hol88 library. When applied to a term, frees returns a list of the free variables in that term. There are no repetitions in the list produced even if there are multiple free instances of some variables.

Failure

Never fails.

Example

Clearly in the following term, x and y are free, whereas z is bound:

- frees $(--'(x=1) / (y=2) / (!z. z \ge 0)'--);$ > val it = [(--'x'--), (--'y'--)] : term list

Comments

The function frees is not in the standard hol98 kernel; the function free_vars is used instead. WARNING: the order of the list returned by frees and free_vars is different.

```
- val tm = (--'x (y:num):bool'--);
> val tm = (--'x y'--) : term
- free_vars tm
> val it = [(--'y'--),(--'x'--)] : term list
- frees tm;
> val it = [(--'x'--),(--'y'--)] : term list
```

It ought to be the case that the result of a call to frees (or free_vars) is treated as a set, that is, the order of the free variables should be immaterial. This is sometimes not possible; for example the result of gen_all (and hence the results of GEN_ALL and new_axiom) necessarily depends on the order of the variables returned from frees. The problem comes when users write code that depends on the order of quantification. For example, contrary to some expectations, it is not the case that (tm being a closed term already)

GEN_ALL (SPEC_ALL tm) = tm

where "=" is interpreted as identity or alpha-convertibility.

See also

freesl, free_in, thm_frees.

freesl

Compat.frees1 : term list -> term list

Synopsis

Returns a list of the free variables in a list of terms.

Description

Found in the hol88 library. When applied to a list of terms, freesl returns a list of the variables which are free in any of those terms. There are no repetitions in the list produced even if several terms contain the same free variable.

Failure

Never fails, unless the hol88 library has not been loaded.

Example

In the following example there are two free instances each of x and y, whereas the only instances of z are bound:

```
- freesl [(--'x+y=2'--), (--'!z. z \ge (x-y)'--)];
val it = [(--'x'--), (--'y'--)] : term list
```

Comments

freesl is not in hol90; use free_varsl instead. WARNING: One can not depend on the order of the list returned by freesl to be identical to that returned by free_varsl. They are coded in terms of frees and free_vars, and thus the discussion in the documentation for frees applies by extension.

See also

frees, free_in, thm_frees.

FREEZE_THEN

FREEZE_THEN : thm_tactical

Synopsis

'Freezes' a theorem to prevent instantiation of its free variables.

Description

FREEZE_THEN expects a tactic-generating function f:thm->tactic and a theorem (A1 |-w) as arguments. The tactic-generating function f is applied to the theorem (w |-w). If

this tactic generates the subgoal:

A ?- t ======== f (w |- w) A ?- t1

then applying FREEZE_THEN f (A1 |-w) to the goal (A ?- t) produces the subgoal:

```
A ?- t
======= FREEZE_THEN f (A1 |- w)
A ?- t1
```

Since the term w is a hypothesis of the argument to the function f, none of the free variables present in w may be instantiated or generalized. The hypothesis is discharged by PROVE_HYP upon the completion of the proof of the subgoal.

Failure

Failures may arise from the tactic-generating function. An invalid tactic arises if the hypotheses of the theorem are not alpha-convertible to assumptions of the goal.

Example

Given the goal (["b < c"; "a < b"], "(SUC a) <= c"), and the specialized variant of the theorem LESS_TRANS:

th = |-!p. a < b /\ b < p ==> a < p

IMP_RES_TAC th will generate several unneeded assumptions:

{b < c, a < b, a < c, !p. c < p ==> b < p, !a'. a' < a ==> a' < b} ?- (SUC a) <= c

which can be avoided by first 'freezing' the theorem, using the tactic

FREEZE_THEN IMP_RES_TAC th

This prevents the variables a and b from being instantiated.

 $\{b < c, a < b, a < c\}$?- (SUC a) <= c

Uses

Used in serious proof hacking to limit the matches achievable by resolution and rewriting.

See also

ASSUME, IMP_RES_TAC, PROVE_HYP, RES_TAC, REWR_CONV.

free_in

free_in : (term -> term -> bool)

Synopsis

Tests if one term is free in another.

Description

When applied to two terms t1 and t2, the function free_in returns true if t1 is free in t2, and false otherwise. It is not necessary that t1 be simply a variable.

Failure

Never fails.

Example

In the following example free_in returns false because the x in SUC x in the second term is bound:

#free_in "SUC x" "!x. SUC x = x + 1";;
false : bool

whereas the following call returns true because the first instance of x in the second term is free, even though there is also a bound instance:

```
#free_in "x:bool" "x /\ (?x. x=T)";;
true : bool
```

See also

frees, freesl, thm_frees.

FRONT_CONJ_CONV

FRONT_CONJ_CONV: (term list -> term -> thm)

Synopsis

Moves a specified conjunct to the beginning of a conjunction.

Description

Given a list of boolean terms [t1;...;t;...;tn] and a term t which occurs in the list, FRONT_CONJ_CONV returns:

|- (t1 /\ ... /\ t /\ ... /\ tn) = (t /\ t1 /\ ... /\ tn)

That is, FRONT_CONJ_CONV proves that t can be moved to the 'front' of a conjunction of several terms.

Failure

FRONT_CONJ_CONV ["t1";...;"tn"] "t" fails if t does not occur in the list [t1,...,tn] or if any of t1, ..., tn do not have type bool.

Comments

This is not a true conversion, so perhaps it ought to be called something else. The system shows its type as (term list -> conv).

front_last

```
Lib.front_last : 'a list -> 'a list * 'a
```

Synopsis

Takes a non-empty list L and returns a pair (front,last) such that front @ [last] = L.

Failure

Fails if the list is empty.

Example

```
- front_last [1];
> val it = ([],1) : int list * int
- front_last [1,2,3];
> val it = ([1,2],3) : int list * int
```

fst

fst : ((* # **) -> *)

176

FULL_SIMP_TAC

Synopsis

Extracts the first component of a pair.

Description

fst (x,y) returns x.

Failure Never fails.

See also

snd, pair.

FULL_SIMP_TAC

simpLib.FULL_SIMP_TAC : simpset -> thm list -> tactic

Synopsis

Simplifies the goal (assumptions as well as conclusion) with the given simpset.

Description

FULL_SIMP_TAC is a powerful simplification tactic that simplifies all of a goal. It proceeds by applying simplification to each assumption of the goal in turn, accumulating simplified assumptions as it goes. These simplified assumptions are used to simplify further assumptions, and all of the simplified assumptions are used as additional rewrites when the conclusion of the goal is simplified.

In addition, simplified assumptions are added back onto the goal using the equivalent of STRIP_ASSUME_TAC and this causes automatic skolemization of existential assumptions, case splits on disjunctions, and the separate assumption of conjunctions. If an assumption is simplified to TRUTH, then this is left on the assumption list. If it an assumption is simplified to falsity, this proves the goal.

Failure

FULL_SIMP_TAC never fails, but it may diverge.

Example

Here FULL_SIMP_TAC is used to prove a goal:

Using LESS_OR_EQ |- $!m n. m \le n \le m \le n \setminus / (m = n)$, a useful case split can be in-

duced in the next goal:

Note that the equality x = y is not used to simplify the subsequent assumptions, but is used to simplify the conclusion of the goal.

Comments

The application of STRIP_ASSUME_TAC to simplified assumptions means that FULL_SIMP_TAC can cause unwanted case-splits and other undesirable transformations to occur in one's assumption list. If one wants to apply the simplifier to assumptions without this occurring, the best approach seems to be the use of RULE_ASSUM_TAC and SIMP_RULE.

See also

ASM_SIMP_TAC, hol_ss, SIMP_CONV, SIMP_RULE, SIMP_TAC.

funpow

funpow : int -> ('a -> 'a) -> 'a -> 'a

Synopsis

Iterates a function a fixed number of times.

Description

funpow n f x applies f to x, n times, giving the result f $(f \dots (f x) \dots)$ where the number of f's is n. funpow 0 f x returns x. If n is negative, funpow n f x returns x.

Failure

funpow n f x fails if any of the n applications of f fail.

Example

Apply tl three times to a list:

- funpow 3 tl [1,2,3,4,5]; > [4, 5] : int list

Apply tl zero times:

- funpow 0 tl [1,2,3,4,5]; > [1; 2; 3; 4; 5] : int list

Apply tl six times to a list of only five elements:

- funpow 6 tl [1,2,3,4,5]; ! Uncaught exception: ! List.Empty

FUN_EQ_CONV

FUN_EQ_CONV : conv

Synopsis

Equates normal and extensional equality for two functions.

Description

The conversion FUN_EQ_CONV embodies the fact that two functions are equal precisely when they give the same results for all values to which they can be applied. When supplied with a term argument of the form f = g, where f and g are functions of type ty1->ty2, FUN_EQ_CONV returns the theorem:

|-(f = g) = (!x. f x = g x)

where x is a variable of type ty1 chosen by the conversion.

Failure

 FUN_EQ_CONV tm fails if tm is not an equation f = g, where f and g are functions.

Uses

Used for proving equality of functions.

See also EXT, X_FUN_EQ_CONV. g

g : term frag list -> proofs

Synopsis

Initializes the subgoal package with a new goal which has no assumptions.

Description

The call

g 'tm'

is equivalent to

```
set_goal([],Term'tm')
```

and clearly more convenient if a goal has no assumptions. For a description of the subgoal package, see set_goal.

Failure

Fails unless the argument term has type bool.

Example

```
- g '(HD[1;2;3] = 1) /\ (TL[1;2;3] = [2;3])';
> val it =
    Proof manager status: 1 proof.
    1. Incomplete:
        Initial goal:
        (HD [1; 2; 3] = 1) /\ (TL [1; 2; 3] = [2; 3])
```

: GoalstackPure.proofs

See also

b, backup, backup_limit, e, expand, expandf, get_state, p, print_state, r, rotate, save_top_thm, set_goal, set_state, top_goal, top_thm.

GEN

```
GEN : (term \rightarrow thm \rightarrow thm)
```

GENL

Synopsis

Generalizes the conclusion of a theorem.

Description

When applied to a term x and a theorem A |-t, the inference rule GEN returns the theorem A |-!x. t, provided x is a variable not free in any of the assumptions. There is no compulsion that x should be free in t.

A |- t ----- GEN "x" [where x is not free in A] A |- !x. t

Failure

Fails if x is not a variable, or if it is free in any of the assumptions.

Example

The following example shows how the above side-condition prevents the derivation of the theorem $x=T \mid - !x \cdot x=T$, which is clearly invalid.

```
#top_print print_all_thm;;
- : (thm -> void)
#let t = ASSUME "x=T";;
t = x = T |- x = T
#GEN "x:bool" t;;
evaluation failed GEN
```

See also

GENL, GEN_ALL, GEN_TAC, SPEC, SPECL, SPEC_ALL, SPEC_TAC.

GENL

```
GENL : (term list -> thm -> thm)
```

Synopsis

Generalizes zero or more variables in the conclusion of a theorem.

Description

When applied to a term list [x1;...;xn] and a theorem A |-t, the inference rule GENL returns the theorem A |-!x1...xn.t, provided none of the variables xi are free in any of the assumptions. It is not necessary that any or all of the xi should be free in t.

A |- t ----- GENL "[x1;...;xn]" [where no xi is free in A] A |- !x1...xn. t

Failure

Fails unless all the terms in the list are variables, none of which are free in the assumption list.

See also

GEN, GEN_ALL, GEN_TAC, SPEC, SPECL, SPEC_ALL, SPEC_TAC.

genvar

genvar : (type -> term)

Synopsis

Returns a variable whose name has not been used previously.

Description

When given a type, genvar returns a variable of that type whose name has not been used for a variable or constant in the HOL session so far.

Failure

Never fails.

Example

The following indicates the typical stylized form of the names (this should not be relied

182

on, of course):

```
#genvar ":bool";;
"GEN%VAR%357" : term
#genvar ":num";;
"GEN%VAR%358" : term
```

Trying to anticipate genvar doesn't work:

```
#let v = mk_var('GEN%VAR%359',":bool");;
v = "GEN%VAR%359" : term
#genvar ":bool";;
"GEN%VAR%360" : term
```

Uses

The unique variables are useful in writing derived rules, for specializing terms without having to worry about such things as free variable capture. If the names are to be visible to a typical user, the function variant can provide rather more meaningful names.

See also

GSPEC, variant.

GEN_ALL

```
Drule.GEN_ALL : thm -> thm
```

Synopsis

Generalizes the conclusion of a theorem over its own free variables.

Description

When applied to a theorem A |-t, the inference rule GEN_ALL returns the theorem A |-!x1...xn. t, where the xi are all the variables, if any, which are free in t but not in the assumptions.

A |- t ----- GEN_ALL A |- !x1...xn. t

Failure

Never fails.

Comments

WARNING: hol90 GEN_ALL does not always return the same result as GEN_ALL in hol88. Sometimes people write code that depends on the order of the quantification. They shouldn't.

See also

```
GEN, GENL, GEN_ALL, SPEC, SPECL, SPEC_ALL, SPEC_TAC.
```

GEN_ALPHA_CONV

```
GEN_ALPHA_CONV : (term -> conv)
```

Synopsis

Renames the bound variable of an abstraction, a quantified term, or other binder application.

Description

The conversion GEN_ALPHA_CONV provides alpha conversion for lambda abstractions of the form "\y.t", quantified terms of the forms "!y.t", "?y.t" or "?!y.t", and epsilon terms of the form "@y.t". In general, if B is a binder constant, then GEN_ALPHA_CONV implements alpha conversion for applications of the form "B y.t". The function is_binder determines what is regarded as a binder in this context.

If tm is an abstraction "\y.t" or an application of a binder to an abstraction "B y.t", where the bound variable y has type ":ty", and if "x" is a variable also of type :ty, then GEN_ALPHA_CONV "x" tm returns one of the theorems:

|- (\y.t) = (\x'. t[x'/y])
|- (B y.t) = (!x'. t[x'/y])

depending on whether the input term is "\y.t" or "B y.t" respectively. The variable x':ty in the resulting theorem is a primed variant of x chosen so as not to be free in the term provided as the second argument to GEN_ALPHA_CONV.

Failure

GEN_ALPHA_CONV x tm fails if x is not a variable, or if tm does not have one of the forms "\y.t" or "B y.t", where B is a binder (that is, is_binder 'B' returns true). GEN_ALPHA_CONV x tm also fails if tm does have one of these forms, but types of the variables x and y differ.

184

See also

ALPHA, ALPHA_CONV, is_binder.

GEN_BETA_CONV

GEN_BETA_CONV : conv

Synopsis

Beta-reduces single or paired beta-redexes, creating a paired argument if needed.

Description

The conversion GEN_BETA_CONV will perform beta-reduction of simple beta-redexes in the manner of BETA_CONV, or of tupled beta-redexes in the manner of PAIRED_BETA_CONV. Unlike the latter, it will force through a beta-reduction by introducing arbitrarily nested pair destructors if necessary. The following shows the action for one level of pairing; others are similar.

GEN_BETA_CONV "(\(x,y). t) p" = t[(FST p)/x, (SND p)/y]

Failure

GEN_BETA_CONV tm fails if tm is neither a simple nor a tupled beta-redex.

Example

The following examples show the action of GEN_BETA_CONV on tupled redexes. In the following, it acts in the same way as PAIRED_BETA_CONV:

```
#GEN_BETA_CONV "(\(x,y). x + y) (1,2)";;
|- (\(x,y). x + y)(1,2) = 1 + 2
```

whereas in the following, the operand of the beta-redex is not a pair, so FST and SND are introduced:

#GEN_BETA_CONV "(\(x,y). x + y) numpair";; |- (\(x,y). x + y)numpair = (FST numpair) + (SND numpair)

The introduction of FST and SND will be done more than once as necessary:

#GEN_BETA_CONV "(\(w,x,y,z). w + x + y + z) (1,triple)";; |- (\(w,x,y,z). w + (x + (y + z)))(1,triple) = 1 + ((FST triple) + ((FST(SND triple)) + (SND(SND triple))))

See also BETA_CONV, PAIRED_BETA_CONV.

185

GEN_MESON_TAC

mesonLib.GEN_MESON_TAC : int -> int -> int -> thm list -> tactic

Synopsis

Performs first order proof search to prove the goal, using both the given theorems and the assumptions in the search.

Description

GEN_MESON_TAC is the function which provides the underlying implementation of the model elimination solver used by both MESON_TAC and ASM_MESON_TAC. The three integer parameters correspond to various ways in which the search can be tuned.

The first is the minimum depth at which to search. Setting this to a number greater than zero can save time if its clear that there will not be a proof of such a small depth. ASM_MESON_TAC and MESON_TAC always use a value of 0 for this parameter.

The second is the maximum depth to which to search. Setting this low will stop the search taking too long, but may cause the engine to miss proofs it would otherwise find. The setting of this variable for ASM_MESON_TAC and MESON_TAC is done through the reference variable mesonLib.max_depth. This is set to 30 by default, but most proofs do not need anything like this depth.

The third parameter is the increment used to increase the depth of search done by the proof search procedure.

The approach used is iterative deepening, so with a call to

GEN_MESON_TAC mn mx inc

the algorithm looks for a proof of depth mn, then for one of depth mn + inc, then at depth mn + 2 * inc etc. Once the depth gets greater than mx, the proof search stops.

Failure

GEN_MESON_TAC fails if it searches to a depth equal to the second integer parameter without finding a proof. Shouldn't fail otherwise.

Uses

The construction of tailored versions of MESON_TAC and ASM_MESON_TAC.

See also

ASM_MESON_TAC, MESON_TAC

GEN_REWRITE_CONV

GEN_REWRITE_CONV : ((conv -> conv) -> thm list -> thm list -> conv)

Synopsis

Rewrites a term, selecting terms according to a user-specified strategy.

Description

Rewriting in HOL is based on the use of equational theorems as left-to-right replacements on the subterms of an object theorem. This replacement is mediated by the use of REWR_CONV, which finds matches between left-hand sides of given equations in a term and applies the substitution.

Equations used in rewriting are obtained from the theorem lists given as arguments to the function. These are at first transformed into a form suitable for rewriting. Conjunctions are separated into individual rewrites. Theorems with conclusions of the form " t " are transformed into the corresponding equations "t = F". Theorems "t" which are not equations are cast as equations of form "t = T".

If a theorem is used to rewrite a term, its assumptions are added to the assumptions of the returned theorem. The matching involved uses variable instantiation. Thus, all free variables are generalized, and terms are instantiated before substitution. Theorems may have universally quantified variables.

The theorems with which rewriting is done are divided into two groups, to facilitate implementing other rewriting tools. However, they are considered in an orderindependent fashion. (That is, the ordering is an implementation detail which is not specified.)

The search strategy for finding matching subterms is the first argument to the rule. Matching and substitution may occur at any level of the term, according to the specified search strategy: the whole term, or starting from any subterm. The search strategy also specifies the depth of the search: recursively up to an arbitrary depth until no matches occur, once over the selected subterm, or any more complex scheme.

Failure

GEN_REWRITE_CONV fails if the search strategy fails. It may also cause a non-terminating sequence of rewrites, depending on the search strategy used.

Uses

This conversion is used in the system to implement all other rewritings conversions, and may provide a user with a method to fine-tune rewriting of terms.

Example

Suppose we have a term of the form:

"(1 + 2) + 3 = (3 + 1) + 2"

and we would like to rewrite the left-hand side with the theorem ADD_SYM without changing the right hand side. This can be done by using:

GEN_REWRITE_CONV (RATOR_CONV o ONCE_DEPTH_CONV) [] [ADD_SYM] mythm

Other rules, such as ONCE_REWRITE_CONV, would match and substitute on both sides, which would not be the desirable result.

As another example, REWRITE_CONV could be implemented as

GEN_REWRITE_CONV TOP_DEPTH_CONV basic_rewrites

which specifies that matches should be searched recursively starting from the whole term of the theorem, and basic_rewrites must be added to the user defined set of theorems employed in rewriting.

See also

ONCE_REWRITE_CONV, PURE_REWRITE_CONV, REWR_CONV, REWRITE_CONV.

GEN_REWRITE_RULE

GEN_REWRITE_RULE : ((conv -> conv) -> thm list -> thm list -> thm -> thm)

Synopsis

Rewrites a theorem, selecting terms according to a user-specified strategy.

Description

Rewriting in HOL is based on the use of equational theorems as left-to-right replacements on the subterms of an object theorem. This replacement is mediated by the use of REWR_CONV, which finds matches between left-hand sides of given equations in a term and applies the substitution.

Equations used in rewriting are obtained from the theorem lists given as arguments to the function. These are at first transformed into a form suitable for rewriting. Conjunctions are separated into individual rewrites. Theorems with conclusions of the form " t " are transformed into the corresponding equations "t = F". Theorems "t" which are not equations are cast as equations of form "t = T".

If a theorem is used to rewrite the object theorem, its assumptions are added to the assumptions of the returned theorem, unless they are alpha-convertible to existing assumptions. The matching involved uses variable instantiation. Thus, all free variables are generalized, and terms are instantiated before substitution. Theorems may have universally quantified variables.

The theorems with which rewriting is done are divided into two groups, to facilitate implementing other rewriting tools. However, they are considered in an orderindependent fashion. (That is, the ordering is an implementation detail which is not specified.)

The search strategy for finding matching subterms is the first argument to the rule. Matching and substitution may occur at any level of the term, according to the specified search strategy: the whole term, or starting from any subterm. The search strategy also specifies the depth of the search: recursively up to an arbitrary depth until no matches occur, once over the selected subterm, or any more complex scheme.

Failure

GEN_REWRITE_RULE fails if the search strategy fails. It may also cause a non-terminating sequence of rewrites, depending on the search strategy used.

Uses

This rule is used in the system to implement all other rewriting rules, and may provide a user with a method to fine-tune rewriting of theorems.

Example

Suppose we have a theorem of the form:

```
thm = |-(1 + 2) + 3 = (3 + 1) + 2
```

and we would like to rewrite the left-hand side with the theorem ADD_SYM without changing the right hand side. This can be done by using:

GEN_REWRITE_RULE (RATOR_CONV o ONCE_DEPTH_CONV) [] [ADD_SYM] mythm

Other rules, such as ONCE_REWRITE_RULE, would match and substitute on both sides, which would not be the desirable result.

As another example, REWRITE_RULE could be implemented as

GEN_REWRITE_RULE TOP_DEPTH_CONV basic_rewrites

which specifies that matches should be searched recursively starting from the whole term of the theorem, and basic_rewrites must be added to the user defined set of theorems employed in rewriting.

See also

ASM_REWRITE_RULE, FILTER_ASM_REWRITE_RULE, ONCE_REWRITE_RULE, PURE_REWRITE_RULE, REWR_CONV, REWRITE_RULE.

GEN_REWRITE_TAC

GEN_REWRITE_TAC : ((conv -> conv) -> thm list -> thm list -> tactic)

Synopsis

Rewrites a goal, selecting terms according to a user-specified strategy.

Description

Distinct rewriting tactics differ in the search strategies used in finding subterms on which to apply substitutions, and the built-in theorems used in rewriting. In the case of REWRITE_TAC, this is a recursive traversal starting from the body of the goal's conclusion part, while in the case of ONCE_REWRITE_TAC, for example, the search stops as soon as a term on which a substitution is possible is found. GEN_REWRITE_TAC allows a user to specify a more complex strategy for rewriting.

The basis of pattern-matching for rewriting is the notion of conversions, through the application of REWR_CONV. Conversions are rules for mapping terms with theorems equating the given terms to other semantically equivalent ones.

When attempting to rewrite subterms recursively, the use of conversions (and therefore rewrites) can be automated further by using functions which take a conversion and search for instances at which they are applicable. Examples of these functions are ONCE_DEPTH_CONV and RAND_CONV. The first argument to GEN_REWRITE_TAC is such a function, which specifies a search strategy; i.e. it specifies how subterms (on which substitutions are allowed) should be searched for.

The second and third arguments are lists of theorems used for rewriting. The order in which these are used is not specified. The theorems need not be in equational form: negated terms, say "~t", are transformed into the equivalent equational form "t = F", while other non-equational theorems with conclusion of form "t" are cast as the corresponding equations "t = T". Conjunctions are separated into the individual components, which are used as distinct rewrites.

Failure

GEN_REWRITE_TAC fails if the search strategy fails. It may also cause a non-terminating sequence of rewrites, depending on the search strategy used. The resulting tactic is invalid when a theorem which matches the goal (and which is thus used for rewriting it

with) has a hypothesis which is not alpha-convertible to any of the assumptions of the goal. Applying such an invalid tactic may result in a proof of a theorem which does not correspond to the original goal.

Uses

Detailed control of rewriting strategy, allowing a user to specify a search strategy.

Example

Given a goal such as:

(-a - (b + c) = a - (c + b))

we may want to rewrite only one side of it with a theorem, say ADD_SYM. Rewriting tactics which operate recursively result in divergence; the tactic ONCE_REWRITE_TAC [ADD_SYM] rewrites on both sides to produce the following goal:

?-a - (c + b) = a - (b + c)

as ADD_SYM matches at two positions. To rewrite on only one side of the equation, the following tactic can be used:

GEN_REWRITE_TAC (RAND_CONV o ONCE_DEPTH_CONV) [] [ADD_SYM]

which produces the desired goal:

?-a - (c + b) = a - (c + b)

As another example, one can write a tactic which will behave similarly to REWRITE_TAC but will also include ADD_CLAUSES in the set of theorems to use always:

See also

ASM_REWRITE_TAC, GEN_REWRITE_RULE, ONCE_REWRITE_TAC, PURE_REWRITE_TAC, REWR_CONV, REWRITE_TAC,

GEN_TAC

GEN_TAC : tactic

Synopsis

Strips the outermost universal quantifier from the conclusion of a goal.

Description

When applied to a goal A ?- !x. t, the tactic GEN_TAC reduces it to A ?- t[x'/x] where x' is a variant of x chosen to avoid clashing with any variables free in the goal's assumption list. Normally x' is just x.

A ?- !x. t ========= GEN_TAC A ?- t[x'/x]

Failure

Fails unless the goal's conclusion is universally quantified.

Uses

The tactic REPEAT GEN_TAC strips away any universal quantifiers, and is commonly used before tactics relying on the underlying term structure.

See also

FILTER_GEN_TAC, GEN, GENL, GEN_ALL, SPEC, SPECL, SPEC_ALL, SPEC_TAC, STRIP_TAC, X_GEN_TAC.

GSPEC

GSPEC : (thm -> thm)

Synopsis

Specializes the conclusion of a theorem with unique variables.

Description

When applied to a theorem A |-!x1...xn.t, where the number of universally quantified variables may be zero, GSPEC returns A |-t[g1/x1]...[gn/xn], where the gi are distinct variable names of the appropriate type, chosen by genvar.

A |- !x1...xn. t GSPEC A |- t[g1/x1]...[gn/xn]

Failure

Never fails.

192

Uses

GSPEC is useful in writing derived inference rules which need to specialize theorems while avoiding using any variables that may be present elsewhere.

See also

GEN, GENL, genvar, GEN_ALL, GEN_TAC, SPEC, SPECL, SPEC_ALL, SPEC_TAC.

GSUBST_TAC

GSUBST_TAC : ((term * term) list -> term -> term) -> thm list -> tactic

Synopsis

Makes term substitutions in a goal using a supplied substitution function.

Description

GSUBST_TAC is the basic substitution tactic by means of which other tactics such as SUBST_OCCS_TAC and SUBST_TAC are defined. Given a list [(v1,w1),...,(vk,wk)] of pairs of terms and a term w, a substitution function replaces occurrences of wj in w with vj according to a specific substitution criterion. Such a criterion may be, for example, to substitute all the occurrences or only some selected ones of each wj in w.

Given a substitution function sfn, GSUBST_TAC sfn [A1|-t1=u1,...,An|-tn=un] (A,t) replaces occurrences of ti in t with ui according to sfn.

A ?- t ======================== GSUBST_TAC sfn [A1|-t1=u1,...,An|-tn=un] A ?- t[u1,...,un/t1,...,tn]

The assumptions of the theorems used to substitute with are not added to the assumptions A of the goal, while they are recorded in the proof. If any Ai is not a subset of A (up to alpha-conversion), then GSUBST_TAC sfn [A1|-t1=u1,...,An|-tn=un] results in an invalid tactic.

GSUBST_TAC automatically renames bound variables to prevent free variables in ui becoming bound after substitution.

Failure

GSUBST_TAC sfn [th1,...,thn] (A,t) fails if the conclusion of each theorem in the list is not an equation. No change is made to the goal if the occurrences to be substituted according to the substitution function sfn do not appear in t.

Uses

GSUBST_TAC is used to define substitution tactics such as SUBST_OCCS_TAC and SUBST_TAC. It may also provide the user with a tool for tailoring substitution tactics.

See also

SUBST1_TAC, SUBST_OCCS_TAC, SUBST_TAC.

GSYM

 $GSYM : (thm \rightarrow thm)$

Synopsis

Reverses the first equation(s) encountered in a top-down search.

Description

The inference rule GSYM reverses the first equation(s) encountered in a top-down search of the conclusion of the argument theorem. An equation will be reversed iff it is not a proper subterm of another equation. If a theorem contains no equations, it will be returned unchanged.

A |- .. (s1 = s2)...(t1 = t2).. ------ GSYM A |- .. (s2 = s1)...(t2 = t1)..

Failure

Never fails, and never loops infinitely.

Example

#ADD;; |- (!n. 0 + n = n) /\ (!m n. (SUC m) + n = SUC(m + n)) Run time: 0.0s #GSYM ADD;; |- (!n. n = 0 + n) /\ (!m n. SUC(m + n) = (SUC m) + n)

See also

NOT_EQ_SYM, REFL, SYM.

194

HALF_MK_ABS

HALF_MK_ABS : (thm -> thm)

Synopsis

Converts a function definition to lambda-form.

Description

When applied to a theorem A |-!x. t1 x = t2, whose conclusion is a universally quantified equation, HALF_MK_ABS returns the theorem A |-t1 = x. t2.

A |- !x. t1 x = t2 ------ HALF_MK_ABS [where x is not free in t1] A |- t1 = (x. t2)

Failure

Fails unless the theorem is a singly universally quantified equation whose left-hand side is a function applied to the quantified variable, or if the variable is free in that function.

See also

ETA_CONV, MK_ABS, MK_COMB, MK_EXISTS.

hidden

hidden : string -> bool

Synopsis

Checks to see if a given name has been hidden.

Description

A call hidden "c" where c is the name of a constant, will check to see if the given name has been hidden, via a previous call to Parse.hide.

Failure

Never fails.

Comments

The hiding of a constant only affects the quotation parser; the constant is still there in a theory.

See also

hide, reveal.

hide

hide : string -> unit

Synopsis

Stops the quotation parser from recognizing a constant.

Description

A call hide "c" where c is the name of a constant, will prevent the quotation parser from parsing it as such; it will just be parsed as a variable. The effect can be reversed by Parse.reveal "c". However, this call does not affect the treatment of overloaded constants. If "+" is overloaded (to addition over the naturals and integers, for example), then hide "+" will not affect its parsing. This must be achieved by first removing the overloading, using clear_overloads_on.

Failure

Never fails.

Comments

The hiding of a constant only affects the quotation parser; the constant is still there in a theory. Further, (re-)defining a string hidden with hide will reveal it once more.

See also

hidden, known_constants, reveal, set_known_constants.

hol_ss

HOLSimps.hol_ss : simpset

196

Synopsis

The most powerful simpset provided by the HOL system.

Description

The hol_ss simpset includes simplifications appropriate for use with the theories of pairs, sums, options, lists, and numbers. It includes an arithmetic decision procedure for linear arithmetic over the natural numbers (ARITH_CONV) and a variety of other powerful techniques. The way in which these components are applied to terms is described in the entry for SIMP_CONV.

Failure

Can't fail as it is not a functional value.

Example

```
- SIMP_CONV hol_ss []
  (Term'P (2 * 2) /\ (P 4 ==> (x = y + 3)) ==> P x /\ y < x');
> val it =
    |- P (2 * 2) /\ (P 4 ==> (x = y + 3)) ==> P x /\ y < x =
        P 4 /\ (P 4 ==> (x = y + 3)) ==> P (y + 3)
    : thm
```

Comments

It can be very difficult to predict what simplification will manage to do to one's terms.

See also

```
++, ASM_SIMP_TAC, bool_ss, FULL_SIMP_TAC, pure_ss, SIMP_CONV, SIMP_TAC.
```

hyp

hyp : (thm -> term list)

Synopsis

Returns the hypotheses of a theorem.

Description

When applied to a theorem A \mid - t, the function hyp returns A, the list of hypotheses of the theorem.

hyp

Failure

Never fails.

See also

dest_thm, concl.

hyp_union

hyp_union : (thm list -> term list)

Synopsis

Returns union of assumption lists of the given theorems.

Description

When applied to a list of theorems, hyp_union returns the union (see union) of their assumption lists. Straight repetitions only arise if there were multiple instances of an assumption in a single assumption list. There is no elimination of alpha-equivalent pairs of assumptions, only ones which are actually equal.

hyp_union [A1 |- t1; ...; An |- tn] = A1 u...u An

Failure

Never fails.

Uses

Designed for internal use, in writing primitive inference rules.

See also

union.

Ι

I : (* -> *)

Synopsis

Performs identity operation: I = x.

Failure

Never fails.

See also

#, B, C, CB, Co, K, KI, o, oo, S, W.

IMP_ANTISYM_RULE

IMP_ANTISYM_RULE : (thm -> thm -> thm)

Synopsis

Deduces equality of boolean terms from forward and backward implications.

Description

When applied to the theorems A1 |-t1 ==> t2 and A2 |-t2 ==> t1, the inference rule IMP_ANTISYM_RULE returns the theorem A1 u A2 |-t1 = t2.

A1 |- t1 ==> t2 A2 |- t2 ==> t1 ----- IMP_ANTISYM_RULE A1 u A2 |- t1 = t2

Failure

Fails unless the theorems supplied are a complementary implicative pair as indicated above.

See also

EQ_IMP_RULE, EQ_MP, EQ_TAC.

IMP_CANON

IMP_CANON : (thm -> thm list)

Synopsis

Puts theorem into a 'canonical' form.

Description

IMP_CANON puts a theorem in 'canonical' form by removing quantifiers and breaking apart conjunctions, as well as disjunctions which form the antecedent of implications. It applies the following transformation rules:

 A |-t1 / 12 A |-!x.t A |-(t1 / 12) ==> t

 A |-t1 A |-t2 A |-t A |-t1 ==> (t2 ==> t)

 A |-(t1 / 12) ==> t A |-(?x.t1) ==> t2

 A |-t1 ==> t A |-t2 ==> t A |-t1[x'/x] ==> t2

Failure

Never fails, but if there is no scope for one of the above reductions, merely gives a list whose only member is the original theorem.

Comments

This is a rather ad-hoc inference rule, and its use is not recommended.

See also

```
CONJ1, CONJ2, CONJUNCTS, DISJ1, DISJ2, EXISTS, SPEC.
```

IMP_CONJ

IMP_CONJ : (thm -> thm -> thm)

Synopsis

Conjoins antecedents and consequents of two implications.

Description

When applied to theorems A1 |-p ==> r and A2 |-q ==> s, the IMP_CONJ inference rule returns the theorem A1 u A2 $|-p / \langle q ==> r / \langle s \rangle$.

A1 |- p ==> r A2 |- q ==> s ----- IMP_CONJ A1 u A2 |- p /\ q ==> r /\ s

Failure

Fails unless the conclusions of both theorems are implicative.

See also

CONJ.

IMP_ELIM

IMP_ELIM : (thm -> thm)

Synopsis

Transforms |-s => t into |- ~s // t.

Description

When applied to a theorem A $\mid -s \mid => t$, the inference rule IMP_ELIM returns the theorem A $\mid - s \mid / t$.

A |- s ==> t ----- IMP_ELIM A |- ~s \/ t

Failure

Fails unless the theorem is implicative.

See also

NOT_INTRO, NOT_ELIM.

IMP_RES_TAC

IMP_RES_TAC : thm_tactic

Synopsis

Enriches assumptions by repeatedly resolving an implication with them.

Description

Given a theorem th, the theorem-tactic IMP_RES_TAC uses RES_CANON to derive a canonical list of implications, each of which has the form:

A |- u1 ==> u2 ==> ... ==> un ==> v

IMP_RES_TAC then tries to repeatedly 'resolve' these theorems against the assumptions of a goal by attempting to match the antecedents u1, u2, ..., un (in that order) to some

assumption of the goal (i.e. to some candidate antecedents among the assumptions). If all the antecedents can be matched to assumptions of the goal, then an instance of the theorem

A u {a1,...,an} |- v

called a 'final resolvent' is obtained by repeated specialization of the variables in the implicative theorem, type instantiation, and applications of modus ponens. If only the first i antecedents u1, ..., ui can be matched to assumptions and then no further matching is possible, then the final resolvent is an instance of the theorem:

A u {a1,...,ai} |- u(i+1) ==> ... ==> v

All the final resolvents obtained in this way (there may be several, since an antecedent ui may match several assumptions) are added to the assumptions of the goal, in the stripped form produced by using STRIP_ASSUME_TAC. If the conclusion of any final resolvent is a contradiction 'F' or is alpha-equivalent to the conclusion of the goal, then IMP_RES_TAC solves the goal.

Failure

Never fails.

See also

IMP_RES_THEN, RES_CANON, RES_TAC, RES_THEN.

IMP_RES_THEN

IMP_RES_THEN : thm_tactical

Synopsis

Resolves an implication with the assumptions of a goal.

Description

The function IMP_RES_THEN is the basic building block for resolution in HOL. This is not full higher-order, or even first-order, resolution with unification, but simply one way simultaneous pattern-matching (resulting in term and type instantiation) of the antecedent of an implicative theorem to the conclusion of another theorem (the candidate antecedent).

Given a theorem-tactic ttac and a theorem th, the theorem-tactical IMP_RES_THEN uses RES_CANON to derive a canonical list of implications from th, each of which has the form:

Ai |- !x1...xn. ui ==> vi

IMP_RES_THEN then produces a tactic that, when applied to a goal A ?- g attempts to match each antecedent ui to each assumption $aj \mid -aj$ in the assumptions A. If the antecedent ui of any implication matches the conclusion aj of any assumption, then an instance of the theorem Ai u {aj} \mid - vi, called a 'resolvent', is obtained by specialization of the variables x1, ..., xn and type instantiation, followed by an application of modus ponens. There may be more than one canonical implication and each implication is tried against every assumption of the goal, so there may be several resolvents (or, indeed, none).

Tactics are produced using the theorem-tactic ttac from all these resolvents (failures of ttac at this stage are filtered out) and these tactics are then applied in an unspecified sequence to the goal. That is,

IMP_RES_THEN ttac th (A ?- g)

has the effect of:

MAP_EVERY (mapfilter ttac [... , (Ai u {aj} |- vi) , ...]) (A ?- g)

where the theorems Ai u {aj} |-vi are all the consequences that can be drawn by a (single) matching modus-ponens inference from the assumptions of the goal A ?- g and the implications derived from the supplied theorem th. The sequence in which the theorems Ai u {aj} |-vi are generated and the corresponding tactics applied is unspecified.

Failure

Evaluating IMP_RES_THEN ttac th fails with 'no implication' if the supplied theorem th is not an implication, or if no implications can be derived from th by the transformation process described under the entry for RES_CANON. Evaluating IMP_RES_THEN ttac th (A ?- g) fails with 'no resolvents' if no assumption of the goal A ?- g can be resolved with the implication or implications derived from th. Evaluation also fails, with 'no tactics', if there are resolvents, but for every resolvent Ai u {aj} |- vi evaluating the application ttac (Ai u {aj} |- vi) fails—that is, if for every resolvent ttac fails to produce a tactic. Finally, failure is propagated if any of the tactics that are produced from the resolvents by ttac fails when applied in sequence to the goal.

Example

The following example shows a straightforward use of IMP_RES_THEN to infer an equational consequence of the assumptions of a goal, use it once as a substitution in the conclusion of goal, and then 'throw it away'. Suppose the goal is:

a + n = a ?- !k. k - n = k

By the built-in theorem:

 $ADD_INV_0 = |- !m n. (m + n = m) ==> (n = 0)$

the assumption of this goal implies that n equals 0. A single-step resolution with this theorem followed by substitution:

IMP_RES_THEN SUBST1_TAC ADD_INV_0

can therefore be used to reduce the goal to:

a + n = a ?- !k. k - 0 = m

Here, a single resolvent a + n = a | - n = 0 is obtained by matching the antecedent of ADD_INV_0 to the assumption of the goal. This is then used to substitute 0 for n in the conclusion of the goal.

See also

IMP_RES_TAC, MATCH_MP, RES_CANON, RES_TAC, RES_THEN.

IMP_TRANS

IMP_TRANS : (thm -> thm -> thm)

Synopsis

Implements the transitivity of implication.

Description

When applied to theorems A1 |-t1 => t2 and A2 |-t2 => t3, the inference rule IMP_TRANS returns the theorem A1 u A2 |-t1 => t3.

A1 |- t1 ==> t2 A2 |- t2 ==> t3 ----- IMP_TRANS A1 u A2 |- t1 ==> t3

Failure

Fails unless the theorems are both implicative, with the consequent of the first being the same as the antecedent of the second (up to alpha-conversion).

See also IMP_ANTISYM_RULE, SYM, TRANS.

Induct

bossLib.Induct : tactic

Synopsis

Performs tactical proof by induction over the type of the goal's outermost universally quantified variable.

Description

Given a universally quantified goal, Induct attempts to perform an induction on the variable that is universally quantified. The induction theorem to be used is looked up in the TypeBase database of theorems about the system's defined types.

Failure

Induct fails if the goal is not universally quantified, or if the type of the variable universally quantified does not have an induction theorem in the TypeBase database (as necessarily happens, for example, with all variable types).

Example

If attempting to prove that

''!list. LENGTH (REVERSE list) = LENGTH list''

one can begin the proof by doing an induction on the list, thus:

where the two subgoals in the list above are the base case and step case respectively of the induction theorem for lists.

The same tactic can be used for induction over numbers, thus:

See also

Induct_on, completeInduct_on, measureInduct_on

INDUCT

INDUCT : ((thm # thm) -> thm)

Synopsis

Performs a proof by mathematical induction on the natural numbers.

Description

The derived inference rule INDUCT implements the rule of mathematical induction:

A1 |- P[0] A2 |- !n. P[n] ==> P[SUC n] ----- INDUCT A1 u A2 |- !n. P[n]

When supplied with a theorem A1 |-P[0], which asserts the base case of a proof of the proposition P[n] by induction on n, and the theorem A2 |-!n.P[n] ==> P[SUC n], which asserts the step case in the induction on n, the inference rule INDUCT returns A1 u A2 |-!n.P[n].

Failure

INDUCT th1 th2 fails if the theorems th1 and th2 do not have the forms A1 |-P[0] and A2 |-!n. P[n] ==> P[SUC n] respectively.

See also

INDUCT_TAC.

INDUCT_TAC

INDUCT_TAC : tactic

Synopsis

Performs tactical proof by mathematical induction on the natural numbers.

Description

INDUCT_TAC reduces a goal !n.P[n], where n has type num, to two subgoals corresponding to the base and step cases in a proof by mathematical induction on n. The induction hypothesis appears among the assumptions of the subgoal for the step case. The specification of INDUCT_TAC is:

where n' is a primed variant of n that does not appear free in the assumptions A (usually, n' just equals n). When INDUCT_TAC is applied to a goal of the form !n.P, where n does not appear free in P, the subgoals are just A ?- P and A u $\{P\}$?- P.

Failure

INDUCT_TAC g fails unless the conclusion of the goal g has the form !n.t, where the variable n has type num.

See also

INDUCT.

INDUCT_THEN

INDUCT_THEN : (thm -> thm_tactic -> tactic)

Synopsis

Structural induction tactic for automatically-defined concrete types.

Description

The function INDUCT_THEN implements structural induction tactics for arbitrary concrete recursive types of the kind definable by define_type. The first argument to INDUCT_THEN

is a structural induction theorem for the concrete type in question. This theorem must have the form of an induction theorem of the kind returned by prove_induction_thm. When applied to such a theorem, the function INDUCT_THEN constructs specialized tactic for doing structural induction on the concrete type in question.

The second argument to INDUCT_THEN is a function that determines what is be done with the induction hypotheses in the goal-directed proof by structural induction. Suppose that th is a structural induction theorem for a concrete data type ty, and that A ?- !x.P is a universally-quantified goal in which the variable x ranges over values of type ty. If the type ty has n constructors C1, ..., Cn and 'Ci(vs)' represents a (curried) application of the ith constructor to a sequence of variables, then if ttac is a function that maps the induction hypotheses hypi of the ith subgoal to the tactic:

A ?- P[Ci(vs)/x] ============== MAP_EVERY ttac hypi A1 ?- Gi

then INDUCT_THEN th ttac is an induction tactic that decomposes the goal A ?- !x.P into a set of n subgoals, one for each constructor, as follows:

A ?- !x.P ================= INDUCT_THEN th ttac A1 ?- G1 ... An ?- Gn

The resulting subgoals correspond to the cases in a structural induction on the variable x of type ty, with induction hypotheses treated as determined by ttac.

Failure

INDUCT_THEN th ttac g fails if th is not a structural induction theorem of the form returned by prove_induction_thm, or if the goal does not have the form A ?- !x:ty.P where ty is the type for which th is the induction theorem, or if ttac fails for any subgoal in the induction.

Example

The built-in structural induction theorem for lists is:

|- !P. P[] /\ (!t. P t ==> (!h. P(CONS h t))) ==> (!l. P l)

When INDUCT_THEN is applied to this theorem, it constructs and returns a specialized induction tactic (parameterized by a theorem-tactic) for doing induction on lists:

#let LIST_INDUCT_THEN = INDUCT_THEN list_INDUCT;; LIST_INDUCT_THEN = - : (thm_tactic -> tactic)

The resulting function, when supplied with the thm_tactic ASSUME_TAC, returns a tactic that decomposes a goal ?- !1.P[1] into the base case ?- P[NIL] and a step case P[1] ?- !h. P[CONS h 1], where the induction hypothesis P[1] in the step case has been put on the assumption list. That is, the tactic:

LIST_INDUCT_THEN ASSUME_TAC

does structural induction on lists, putting any induction hypotheses that arise onto the assumption list:

A ?- !l. P A -- P[NIL/1] A u {P[1'/1]} ?- !h. P[(CONS h l')/1]

Likewise LIST_INDUCT_THEN STRIP_ASSUME_TAC will also do induction on lists, but will strip induction hypotheses apart before adding them to the assumptions (this may be useful if P is a conjunction or a disjunction, or is existentially quantified). By contrast, the tactic:

LIST_INDUCT_THEN MP_TAC

will decompose the goal as follows:

A ?- !1. P A !- P[NIL/1] A ?- P[1'/1] ==> !h. P[CONS h l'/1]

That is, the induction hypothesis becomes the antecedent of an implication expressing the step case in the induction, rather than an assumption of the step-case subgoal.

define_type, new_recursive_definition, prove_cases_thm,
prove_constructors_distinct, prove_constructors_one_one, prove_induction_thm,
prove_rec_fn_exists.
```

initial_rws

initial_rws : unit -> computeLib.comp_rws

Synopsis

Creates a new simplification set to use with computeLib.CBV_CONV for basic computations.

DESCRIPTION This function creates a new simplification set to use with the compute library performing computations about operations on primitive booleans and numerals

(in binary representation) such as LET, conditional, implication, conjunction, disjunction, negation, FST, SND, addition, subtraction, multiplication, division, modulo, exponentiation, etc.

We assume here that the canonical representation of the naturals is the binary one. Therefore, defining function by pattern matching using SUC will not be recognized. For instance, defining the exponentaition function as

|- (n EXP 0 = 1) /\ (n EXP (SUC p) = n * n EXP p)

It is possible to make this definition work by using the following lemma:

|- (exp n p = if n = 0 then 1 else n * (exp n (p-1)))

Example

```
- CBV_CONV (initial_rws()) (--'EVERY (\n. EVEN n) [4;6;8;10;12;14;16]'--); > val it = |- EVERY (\n. EVEN n) [4; 6; 8; 10; 12; 14; 16] = T : Thm.thm
```

See also

CBV_CONV, REDUCE_CONV

inst

```
inst : hol_type subst -> term -> term
```

Synopsis

Performs type instantiations in a term. NOT the same as the hol88 inst; the first argument (the "away-from" list) used in hol88 inst is unnecessary and hence dispensed with, PLUS hol90 insists that all redexes be type variables.

Description

The function inst should be used as follows:

```
inst [{redex_1, residue_1}, ..., {redex_n, residue_n}] tm
```

where the redexes are all hol_type variables, and the residues all hol_types and tm a term to be type-instantiated. This call will replace each occurrence of a redex in tm by its associated residue. Replacement is done in parallel, i.e., once a redex has been replaced by its residue, at some place in the term, that residue at that place will not

INST

itself be replaced in the current call. Bound term variables may be renamed in order to preserve the term structure.

Failure

Fails if there exists a redex in the substition that is not a type variable.

Example

Uses

Performing internal functions connected with type instantiation.

See also

type_subst, Compat.inst_type, INST_TYPE.

INST

INST : (term,term) subst -> thm -> thm

Synopsis

Instantiates free variables in a theorem.

Description

INST is a rule for substituting arbitrary terms for free variables in a theorem:

where the variables x1, \ldots , xn are not free in the assumptions A.

Failure

INST fails if a variable being instantiated is free in the assumptions.

Example

In the following example a theorem is instantiated for a specific term:

See also

INST_TY_TERM, INST_TYPE, ISPEC, ISPECL, SPECL, SUBS, subst, SUBST.

INST_TYPE

INST_TYPE : (hol_type,hol_type) subst -> thm -> thm

Synopsis

Instantiates types in a theorem.

Description

INST_TYPE is a primitive rule in the HOL logic, which allows instantiation of type vari-

ables.

A |- t
----- INST_TYPE[vty1|->ty1,..., vtyn|->tyn]
A |- t[ty1,...,tyn/vty1,...,vtyn]

where none of the types vtyi are free in the assumption list. Variables will be renamed if necessary to prevent distinct variables becoming identical after the instantiation.

Failure

INST_TYPE fails if any of the type variables occurs free in the hypotheses of the theorem, or if upon instantiation two distinct variables (with the same name) become equal.

Uses

INST_TYPE is employed to make use of polymorphic theorems.

Example

Suppose one wanted to specialize the theorem EQ_SYM_EQ for particular values, the first attempt could be to use SPECL as follows:

```
- SPECL [''a:num'', ''b:num''] EQ_SYM_EQ;
uncaught exception HOL_ERR
```

The failure occurred because EQ_SYM_EQ contains polymorphic types. The desired specialization can be obtained by using INST_TYPE:

See also

INST, INST_TY_TERM.

INST_TY_TERM

```
INST_TY_TERM :
  (term,term)subst * (hol_type,hol_type)subst -> thm -> thm
```

Synopsis

Instantiates terms and types of a theorem.

Description

INST_TY_TERM instantiates types in a theorem, in the same way INST_TYPE does. Then it instantiates some or all of the free variables in the resulting theorem, in the same way as INST.

Failure

INST_TY_TERM fails under the same conditions as either INST or INST_TYPE fail.

See also

INST, INST_TYPE, ISPEC, SPEC, SUBS, SUBST.

intersect

intersect : (* list -> * list -> * list)

Synopsis

Computes the intersection of two 'sets'.

Description

intersect 11 12 returns a list consisting of those elements of 11 that also appear in 12.

Failure

Never fails.

Example

```
#intersect [1;2;3] [3;5;4;1];;
[1; 3] : int list
```

#intersect [1;2;4;1] [1;2;3;2];;
[1; 2; 1] : int list

See also

setify, set_equal, union, subtract.

int_of_string

Compat.int_of_string : string -> int

Synopsis

Maps a string of numbers to the corresponding integer.

Description

Found in the hol88 library. Given a string representing an integer in standard decimal notation, possibly including a leading plus sign or minus sign and/or leading zeros, int_of_string returns the corresponding integer constant.

Failure

Fails unless the string is a valid decimal representation as specified above. It will not be found unless the hol88 library has been loaded.

Comments

Not found in hol90, since the author always got it backwards; use string_to_int instead. Likewise, string_of_int is not found in hol90; use int_to_string.

See also

ascii, ascii_code, string_of_int, int_to_string, string_to_int.

ISPEC

```
ISPEC : (term \rightarrow thm \rightarrow thm)
```

Synopsis

Specializes a theorem, with type instantiation if necessary.

Description

This rule specializes a quantified variable as does SPEC; it differs from it in also instantiating the type if needed:

A |- !x:ty.tm ----- ISPEC "t:ty'" A |- tm[t/x]

(where t is free for x in tm, and ty' is an instance of ty).

Failure

ISPEC fails if the input theorem is not universally quantified, if the type of the given term is not an instance of the type of the quantified variable, or if the type variable is free in the assumptions.

See also

INST_TY_TERM, INST_TYPE, ISPECL, SPEC, match_term.

ISPECL

ISPECL : (term list -> thm -> thm)

Synopsis

Specializes a theorem zero or more times, with type instantiation if necessary.

Description

ISPECL is an iterative version of ISPEC

A |- !x1...xn.t ------ ISPECL ["t1",...,"tn"] A |- t[t1,...tn/x1,...,xn]

(where ti is free for xi in tm).

Failure

ISPECL fails if the list of terms is longer than the number of quantified variables in the term, if the type instantiation fails, or if the type variable being instantiated is free in the assumptions.

See also

INST_TYPE, INST_TY_TERM, ISPEC, MATCH, SPEC, SPECL.

is_abs

is_abs : (term -> bool)

Synopsis

Tests a term to see if it is an abstraction.

Description

is_abs "\var. t" returns true. If the term is not an abstraction the result is false.

Failure

Never fails.

See also

mk_abs, dest_abs, is_var, is_const, is_comb.

is_axiom

is_axiom : ((string # string) -> bool)

Synopsis

Tests if there is an axiom with the given name in the given theory.

Description

The call is_axiom('th', 'ax'), where th is the name of a theory (as usual '-' means the current theory), tests if there is an axiom called ax in that theory.

Failure

Fails unless the given theory is an ancestor.

Example

```
#is_axiom('bool','BOOL_CASES_AX');;
true : bool
```

#is_axiom('bool','INFINITY_AX');;
false : bool

```
#is_axiom('ind','INFINITY_AX');;
true : bool
```

See also

axioms, new_axiom.

is_binder

is_binder : (string -> bool)

Determines whether a given string represents a binder.

Description

This predicate returns true if the given string argument is the name of a binder: it returns false otherwise.

Example

```
#binders 'bool';;
["$?!"; "$!"; "$@"] : term list
#is_binder '$?!';;
false : bool
#is_binder '?!';;
true : bool
```

See also

binders, is_binder_type, is_infix, is_constant

is_comb

```
is_comb : (term -> bool)
```

Synopsis

Tests a term to see if it is a combination (function application).

Description

is_comb "t1 t2" returns true. If the term is not a combination the result is false.

Failure

Never fails

See also

```
mk_comb, dest_comb, is_var, is_const, is_abs.
```

is_cond

is_cond : (term -> bool)

is_conj

Synopsis

Tests a term to see if it is a conditional.

Description

is_cond "t => t1 | t2" returns true. If the term is not a conditional the result is false.

Failure

Never fails.

See also

mk_cond, dest_cond.

```
is_conj : (term -> bool)
```

Synopsis

Tests a term to see if it is a conjunction.

Description

is_conj "t1 /\ t2" returns true. If the term is not a conjunction the result is false.

Failure

Never fails.

See also

mk_conj, dest_conj.

is_cons

is_cons : (term -> bool)

Synopsis

Tests a term to see if it is an application of CONS.

Description

is_cons returns true of a term representing a non-empty list. Otherwise it returns false.

Failure

Never fails.

See also

mk_cons, dest_cons, mk_list, dest_list, is_list.

is_const

is_const : (term -> bool)

Synopsis

Tests a term to see if it is a constant.

Description

is_const "const:ty" returns true. If the term is not a constant the result is false.

Failure

Never fails.

See also

mk_const, dest_const, is_var, is_comb, is_abs.

is_constant

```
is_constant : (string -> bool)
```

Synopsis

Determines whether a string is the name of a constant.

Description

This predicate returns true if the given string argument is the name of a constant defined in the current theory or its ancestors: it returns false otherwise.

Example

```
#is_constant 'SUC';;
true : bool
#is_constant '3';;
true : bool
#is_constant '$!';;
false : bool
#is_constant '!';;
true : bool
#is_constant 'xx';;
false : bool
```

See also

is_infix, is_binder

is_disj

```
is_disj : (term -> bool)
```

Synopsis

Tests a term to see if it is a disjunction.

Description

is_disj "t1 \/ t2" returns true. If the term is not a disjunction the result is false.

Failure

Never fails.

See also

mk_disj, dest_disj.

is_eq

is_eq : (term -> bool)

Tests a term to see if it is an equation.

Description

is_eq "t1 = t2" returns true. If the term is not an equation the result is false.

Failure

Never fails.

See also

mk_eq, dest_eq.

is_exists

```
is_exists : (term -> bool)
```

Synopsis

Tests a term to see if it as an existential quantification.

Description

is_exists "?var. t" returns true. If the term is not an existential quantification the result is false.

Failure

Never fails.

See also

mk_exists, dest_exists.

is_forall

is_forall : (term -> bool)

Synopsis

Tests a term to see if it is a universal quantification.

Description

is_forall "!var. t" returns true. If the term is not a universal quantification the result
is false.

Failure

Never fails.

See also

mk_forall, dest_forall.

is_hidden

is_hidden : (string -> bool)

Synopsis

Determines whether a constant is hidden.

Description

This predicate returns true if the named ML constant has been hidden by the function hide_constant; it returns false if the constant is not hidden. Hiding a constant forces the quotation parser to treat the constant as a variable (lexical rules permitting).

Example

```
#is_hidden '0';;
false : bool
#hide_constant '0';;
() : void
#is_hidden '0';;
true : bool
#unhide_constant '0';;
() : void
#is_hidden '0';;
false : bool
```

See also

hide_constant, unhide_constant

is_imp

is_imp : (term -> bool)

Synopsis

Tests a term to see if it is an implication (or a negation).

Description

is_imp "t1 ==> t2" returns true. is_imp "~t" returns true. If the term is neither an
implication nor a negation the result is false.

Failure

Never fails.

Comments

Yields true of negations because dest_imp destructs negations (for compatibility with PPLAMBDA code).

See also

mk_imp, dest_imp.

is_infix

is_infix : (string -> bool)

Synopsis

Determines whether an operator is infix.

Description

This predicate returns true if the given string argument is the name of an infix operator (a constant); it returns false otherwise.

Example

```
#is_infix '$+';;
false : bool
```

```
#is_infix '+';;
true : bool
```

#is_infix 'SUC';;
false : bool

See also

infixes, is_binder, is_constant.

is_let

is_let : (term -> bool)

Synopsis

Tests a term to see if it is a let-expression.

Description

is_let "LET f x" returns true. If the term is not a let-expression (or of the more general "LET f x" form) the result is false.

Failure

Never fails.

Example

```
#is_let "LET ($= 1) 2";;
true : bool
```

#is_let "let x = 2 in (x = 1)";;
true : bool

See also

mk_let, dest_let.

is_list

is_list : (term -> bool)

Synopsis

Tests a term to see if it is a list.

Description

is_list returns true of a term representing a list. Otherwise it returns false.

Failure

Never fails.

See also

mk_list, dest_list, mk_cons, dest_cons, is_cons.

is_neg

```
is_neg : (term -> bool)
```

Synopsis

Tests a term to see if it is a negation.

Description

is_neg "~t" returns true. If the term is not a negation the result is false.

Failure

Never fails.

See also

mk_neg, dest_neg.

is_pabs

is_pabs : (term -> bool)

is_pair

Synopsis

Tests a term to see if it is a paired abstraction.

Description

is_pabs "\(v1..(..)..vn). t" returns true. If the term is not a paired abstraction the result is false.

Failure

Never fails.

See also

mk_pabs, dest_pabs, is_abs, is_var, is_const, is_comb.

is_pair

```
is_pair : (term -> bool)
```

Synopsis

Tests a term to see if it is a pair.

Description

is_pair "(t1,t2)" returns true. If the term is not a pair the result is false.

Failure

Never fails.

See also

mk_pair, dest_pair.

is_select

is_select : (term -> bool)

Synopsis

Tests a term to see if it is a choice binding.

Description

is_select "@var. t" returns true. If the term is not an epsilon-term the result is false.

Failure

Never fails.

See also

```
mk_select, dest_select.
```

is_type

```
is_type : (string -> bool)
```

Synopsis

Tests whether a string is the name of a type.

Description

is_type 'op' returns true if 'op' is the name of a type or type operator and false otherwise.

Failure

Never fails.

See also

arity.

is_var

is_var : (term -> bool)

Synopsis

Tests a term to see if it is a variable.

Description

is_var "var:ty" returns true. If the term is not a variable the result is false.

Failure

Never fails.

See also

mk_var, dest_var, is_const, is_comb, is_abs.

is_vartype

is_vartype : (type -> bool)

Synopsis

Tests a type to see if it is a type variable.

Description

is_vartype(":*...") returns true. For types which are not type variables it returns
false.

Failure

Never fails.

Example

#is_vartype ":*test";;
true : bool
#is_vartype ":bool";;
false : bool

#is_vartype ":* -> bool";;
false : bool

See also

mk_vartype, dest_vartype.

itlist

itlist : ((* -> ** -> **) -> * list -> ** -> **)

List iteration function. Applies a binary function between adjacent elements of a list.

Description

itlist f [x1;...;xn] y returns

f x1 (f x2 ... (f xn y)...)

It returns y if list is empty.

Failure

Never fails.

Example

#itlist (\x y. x + y) [1;2;3;4] 0;; 10 : int

See also

rev_itlist, end_itlist.

itlist2

itlist2 : (((* # **) -> *** -> ***) -> (* list # ** list) -> *** -> ***)

Synopsis

Applies a paired function between adjacent elements of 2 lists.

Description

itlist2 f ([x1;...;xn],[y1;...;yn]) z returns

```
f (x1,y1) (f (x2,y2) ... (f (xn,yn) z)...)
```

It returns z if both lists are empty.

Failure

Fails with itlist2 if the two lists are of different lengths.

Example

#itlist2 (\(x,y) z. (x * y) + z) ([1;2],[3;4]) 0;; 11 : int

See also

itlist, rev_itlist, end_itlist, uncurry.

Κ

K : (* -> ** -> *)

Synopsis

Forms a constant function: (K x) y = x.

Failure

Never fails.

See also

#, B, C, CB, Co, I, KI, o, oo, S, W.

known_constants

Parse.known_constants : unit -> string list

Synopsis

Returns the list of constants known to the parser.

Description

A call to this functions returns the list of constants that will be treated as such by the parser. Those constants with names not on the list will be parsed as if they were variables.

Failure

Never fails.

See also

hide, reveal, set_known_constants.

LAND_CONV

LAND_CONV : conv -> conv

Synopsis

Applies a conversion to the left-hand argument of a binary operator.

Description

If c is a conversion that maps a term t1 to the theorem |-t1 = t1', then the conversion LAND_CONV c maps applications of the form f t1 t2 to theorems of the form:

|-f t1 t2 = f t1' t2

Failure

LAND_CONV c tm fails if tm is not an application where the rator of the application is in turn another application, or if tm has this form but the conversion c fails when applied to the term t2. The function returned by LAND_CONV c may also fail if the ML function c:term->thm is not, in fact, a conversion (i.e. a function that maps a term t to a theorem |-t = t').

Example

- LAND_CONV REDUCE_CONV (Term'(3 + 5) * 7'); > val it = |- (3 + 5) * 7 = 8 * 7 : Thm.thm

See also

ABS_CONV, BINOP_CONV, RAND_CONV, RATOR_CONV.

last

Compat.last : 'a list -> 'a

Computes the last element of a list.

Description

last [x1,...,xn] returns xn.

Failure

Found in the hol88 library. Fails with last if the list is empty. It will not be found unless the hol88 library has been loaded.

Comments

Not in hol90, since it was never used in the implementation.

See also

butlast, hd, tl, el, null.

LEFT_AND_EXISTS_CONV

LEFT_AND_EXISTS_CONV : conv

Synopsis

Moves an existential quantification of the left conjunct outwards through a conjunction.

Description

When applied to a term of the form $(?x.P) \land Q$, the conversion LEFT_AND_EXISTS_CONV returns the theorem:

|- (?x.P) / Q = (?x'. P[x'/x] / Q)

where x, is a primed variant of x that does not appear free in the input term.

Failure

Fails if applied to a term not of the form (?x.P) /\ Q.

See also

AND_EXISTS_CONV, EXISTS_AND_CONV, RIGHT_AND_EXISTS_CONV.

LEFT_AND_FORALL_CONV

LEFT_AND_FORALL_CONV : conv

Moves a universal quantification of the left conjunct outwards through a conjunction.

Description

When applied to a term of the form $(!x.P) \land Q$, the conversion LEFT_AND_FORALL_CONV returns the theorem:

|-(!x.P) / Q = (!x'. P[x'/x] / Q)

where $x^{,i}$ is a primed variant of x that does not appear free in the input term.

Failure

Fails if applied to a term not of the form (!x.P) / Q.

See also

AND_FORALL_CONV, FORALL_AND_CONV, RIGHT_AND_FORALL_CONV.

LEFT_IMP_EXISTS_CONV

LEFT_IMP_EXISTS_CONV : conv

Synopsis

Moves an existential quantification of the antecedent outwards through an implication.

Description

When applied to a term of the form (?x.P) ==> Q, the conversion LEFT_IMP_EXISTS_CONV returns the theorem:

|-(?x.P) => Q = (!x'. P[x'/x] => Q)

where x, is a primed variant of x that does not appear free in the input term.

Failure

Fails if applied to a term not of the form $(?x.P) \implies Q$.

See also

FORALL_IMP_CONV, RIGHT_IMP_FORALL_CONV.

LEFT_IMP_FORALL_CONV

LEFT_IMP_FORALL_CONV : conv

Moves a universal quantification of the antecedent outwards through an implication.

Description

When applied to a term of the form (!x.P) ==> Q, the conversion LEFT_IMP_FORALL_CONV returns the theorem:

|- (!x.P) ==> Q = (?x'. P[x'/x] ==> Q)

where $x^{,i}$ is a primed variant of x that does not appear free in the input term.

Failure

Fails if applied to a term not of the form $(!x.P) \implies Q$.

See also

EXISTS_IMP_CONV, RIGHT_IMP_FORALL_CONV.

LEFT_OR_EXISTS_CONV

LEFT_OR_EXISTS_CONV : conv

Synopsis

Moves an existential quantification of the left disjunct outwards through a disjunction.

Description

When applied to a term of the form $(?x.P) \setminus / Q$, the conversion LEFT_OR_EXISTS_CONV returns the theorem:

 $|-(?x.P) \setminus Q = (?x'. P[x'/x] \setminus Q)$

where x, is a primed variant of x that does not appear free in the input term.

Failure

Fails if applied to a term not of the form (?x.P) \setminus Q.

See also

EXISTS_OR_CONV, OR_EXISTS_CONV, RIGHT_OR_EXISTS_CONV.

LEFT_OR_FORALL_CONV

LEFT_OR_FORALL_CONV : conv

Moves a universal quantification of the left disjunct outwards through a disjunction.

Description

When applied to a term of the form $(!x.P) \setminus / Q$, the conversion LEFT_OR_FORALL_CONV returns the theorem:

 $|-(!x.P) \setminus Q = (!x'. P[x'/x] \setminus Q)$

where x, is a primed variant of x that does not appear free in the input term.

Failure

Fails if applied to a term not of the form $(!x.P) \setminus Q$.

See also

OR_FORALL_CONV, FORALL_OR_CONV, RIGHT_OR_FORALL_CONV.

lhs

lhs : (term -> term)

Synopsis

Returns the left-hand side of an equation.

Description

lhs "t1 = t2" returns "t1".

Failure

Fails with lhs if the term is not an equation.

See also

rhs, dest_eq.

libraries

libraries : (void -> string list)

Evaluating libraries() returns a list of the libraries that have been successfully loaded during the current session.

Failure

Never fails.

See also

library_pathname, load_library.

LIST_BETA_CONV

LIST_BETA_CONV : conv

Synopsis

Performs an iterated beta conversion.

Description

The conversion LIST_BETA_CONV maps terms of the form

"(\x1 x2 ... xn. u) v1 v2 ... vn"

to the theorems of the form

|- (\x1 x2 ... xn. u) v1 v2 ... vn = u[v1/x1][v2/x2] ... [vn/xn]

where u[vi/xi] denotes the result of substituting vi for all free occurrences of xi in u, after renaming sufficient bound variables to avoid variable capture.

Failure

LIST_BETA_CONV tm fails if tm does not have the form "($x1 \ldots xn$. u) v1 ... vn" for n greater than 0.

Example

#LIST_BETA_CONV "(\x y. x+y) 1 2";; |- (\x y. x + y)1 2 = 1 + 2

See also BETA_CONV, BETA_RULE, BETA_TAC, RIGHT_BETA, RIGHT_LIST_BETA.

LIST_CONJ

LIST_CONJ : (thm list -> thm)

Synopsis

Conjoins the conclusions of a list of theorems.

Description

A1 |- t1 ... An |- tn ----- LIST_CONJ A1 u ... u An |- t1 /\ ... /\ tn

Failure

LIST_CONJ will fail with 'end_itlist' if applied to an empty list of theorems.

Comments

The system shows the type as proof.

LIST_CONJ does not check for alpha-equivalence of assumptions when forming their union. If a particular assumption is duplicated within one of the input theorems assumption lists, then it may be duplicated in the resulting assumption list.

See also

BODY_CONJUNCTS, CONJ, CONJUNCT1, CONJUNCT2, CONJUNCTS, CONJ_PAIR, CONJ_TAC.

LIST_INDUCT

LIST_INDUCT : ((thm # thm) -> thm)

Synopsis

Performs proof by structural induction on lists.

Description

The derived inference rule LIST_INDUCT implements the rule of mathematical induction:

A1 |- P[NIL/1] A2 |- !t. P[t/1] ==> !h. P[CONS h t/1] ------ LIST_INDUCT A1 u A2 |- !l. P

When supplied with a theorem A1 |- P[NIL], which asserts the base case of a proof of the proposition P[1] by structural induction on the list 1, and the theorem

A2 |- !t. P[t] ==> !h. P[CONS h t]

which asserts the step case in the induction on 1, the inference rule LIST_INDUCT returns A1 u A2 |- !1. P[1].

Failure

LIST_INDUCT th1 th2 fails if the theorems th1 and th2 do not have the forms A1 |-P[NIL] and A2 |-!t.P[t] ==> !h.P[CONS h t] respectively (where the empty list NIL in th1 and the list CONS h t in th2 have the same type).

See also

LIST_INDUCT_TAC.

LIST_INDUCT_TAC

LIST_INDUCT_TAC : tactic

Synopsis

Performs tactical proof by structural induction on lists.

Description

LIST_INDUCT_TAC reduces a goal !1.P[1], where 1 ranges over lists, to two subgoals corresponding to the base and step cases in a proof by structural induction on 1. The induction hypothesis appears among the assumptions of the subgoal for the step case. The specification of LIST_INDUCT_TAC is:

where 1' is a primed variant of 1 that does not appear free in the assumptions A (usually, 1' is just 1). When LIST_INDUCT_TAC is applied to a goal of the form !1.P, where 1 does not appear free in P, the subgoals are just A ?- P and A u {P} ?- !h.P.

Failure

LIST_INDUCT_TAC g fails unless the conclusion of the goal g has the form !1.t, where the variable 1 has type (ty)list for some type ty.

See also

LIST_INDUCT.

list_mk_abs

list_mk_abs : ((term list # term) -> term)

Synopsis

Iteratively constructs abstractions.

Description

list_mk_abs(["x1";...;"xn"],"t") returns "\x1 ... xn. t".

Failure

Fails with list_mk_abs if the terms in the list are not variables.

Comments

The system shows the type as goal -> term.

See also

strip_abs, mk_abs.

list_mk_comb

list_mk_comb : ((term # term list) -> term)

Synopsis

Iteratively constructs combinations (function applications).

Description

list_mk_comb("t",["t1";...;"tn"]) returns "t t1 ... tn".

Failure

Fails with list_mk_comb if the types of t1,...,tn are not equal to the argument types of t. It is not necessary for all the arguments of t to be given. In particular the list of terms t1,...,tn may be empty.

Example

```
#list_mk_comb("1",[]);;
"1" : term
#list_mk_comb("$/\",["T"]);;
"$/\ T" : term
#list_mk_comb("$/\",["1"]);;
evaluation failed list_mk_comb
```

See also

strip_comb, mk_comb.

list_mk_conj

```
list_mk_conj : (term list -> term)
```

Synopsis

Constructs the conjunction of a list of terms.

Description

list_mk_conj(["t1";...;"tn"]) returns "t1 /\ ... /\ tn".

Failure

Fails with list_mk_conj if the list is empty or if the list has more than one element, one or more of which are not of type ":bool".

Example

```
#list_mk_conj ["T";"F";"T"];;
"T /\ F /\ T" : term
#list_mk_conj ["T";"1";"F"];;
evaluation failed list_mk_conj
#list_mk_conj ["1"];;
"1" : term
```

See also

conjuncts, mk_conj.

list_mk_disj

```
list_mk_disj : (term list -> term)
```

Synopsis

Constructs the disjunction of a list of terms.

Description

list_mk_disj(["t1";...;"tn"]) returns "t1 \/ ... \/ tn".

Failure

Fails with list_mk_disj if the list is empty or if the list has more than one element, one or more of which are not of type ":bool".

Example

```
#list_mk_disj ["T";"F";"T"];;
"T \/ F \/ T" : term
#list_mk_disj ["T";"1";"F"];;
evaluation failed list_mk_disj
#list_mk_disj ["1"];;
"1" : term
```

See also

disjuncts, mk_disj.

list_mk_exists

list_mk_exists : ((term list # term) -> term)

Synopsis

Iteratively constructs existential quantifications.

Description

```
list_mk_exists(["x1";...;"xn"],"t") returns "?x1 ... xn. t".
```

Failure

Fails with list_mk_exists if the terms in the list are not variables or if t is not of type ":bool" and the list of terms is non-empty. If the list of terms is empty the type of t can be anything.

Comments

The system shows the type as (goal -> term).

See also

strip_exists, mk_exists.

LIST_MK_EXISTS

LIST_MK_EXISTS : (term list -> thm -> thm)

Synopsis

Multiply existentially quantifies both sides of an equation using the given variables.

Description

When applied to a list of terms [x1;...;xn], where the xi are all variables, and a theorem A |-t1 = t2, the inference rule LIST_MK_EXISTS existentially quantifies both sides

of the equation using the variables given, none of which should be free in the assumption list.

A |- t1 = t2 ----- LIST_MK_EXISTS ["x1";...;"xn"] A |- (?x1...xn. t1) = (?x1...xn. t2)

Failure

Fails if any term in the list is not a variable or is free in the assumption list, or if the theorem is not equational.

See also

EXISTS_EQ, MK_EXISTS.

list_mk_forall

```
list_mk_forall : ((term list # term) -> term)
```

Synopsis

Iteratively constructs a universal quantification.

Description

```
list_mk_forall(["x1";...;"xn"],"t") returns "!x1 ... xn. t".
```

Failure

Fails with list_mk_forall if the terms in the list are not variables or if t is not of type ":bool" and the list of terms is non-empty. If the list of terms is empty the type of t can be anything.

Comments

The system shows the type as (goal -> term).

See also

```
strip_forall, mk_forall.
```

list_mk_imp

```
list_mk_imp : (goal -> term)
```

Iteratively constructs implications.

Description

```
list_mk_imp(["t1";...;"tn"],"t") returns "t1 ==> ( ... (tn ==> t)...)".
```

Failure

Fails with list_mk_imp if any of t1,...,tn are not of type ":bool" or if the list of terms is non-empty and t is not of type ":bool". If the list of terms is empty the type of t can be anything.

Example

```
#list_mk_imp (["T";"F"],"T");;
"T ==> F ==> T" : term
#list_mk_imp (["T";"1"],"T");;
evaluation failed list_mk_imp
#list_mk_imp (["T";"F"],"1");;
evaluation failed list_mk_imp
#list_mk_imp ([],"1");;
"1" : term
```

See also

strip_imp, mk_imp.

list_mk_pair

list_mk_pair : (term list -> term)

Synopsis

Constructs a tuple from a list of terms.

Description

list_mk_pair(["t1";...;"tn"]) returns "(t1,...,tn)".

Failure

Fails with list_mk_pair if the list is empty.

Example

```
#list_mk_pair ["1";"T";"2"];;
"1,T,2" : term
#list_mk_pair ["1"];;
"1" : term
```

See also

strip_pair, mk_pair.

LIST_MP

LIST_MP : (thm list -> thm -> thm)

Synopsis

Performs a chain of Modus Ponens inferences.

Description

When applied to theorems A1 |-t1, ..., An |-tn and a theorem which is a chain of implications with the successive antecedents the same as the conclusions of the theorems in the list (up to alpha-conversion), A $|-t1 ==> \ldots => tn ==> t$, the LIST_MP inference rule performs a chain of MP inferences to deduce A u A1 u ... u An |-t.

A1 |- t1 ... An |- tn A |- t1 ==> ... ==> tn ==> t ------ LIST_MP A u A1 u ... u An |- t

Failure

Fails unless the theorem is a chain of implications whose consequents are the same as the conclusions of the list of theorems (up to alpha-conversion), in sequence.

See also

EQ_MP, MATCH_MP, MATCH_MP_TAC, MP, MP_TAC.

list_of_binders

list_of_binders : term list

List of binders in the current theory.

Description

For implementation reasons, a list containing the binders in the current theory is maintained in the assignable ML variable <code>list_of_binders</code>. This variable is not for general use, and users should never make assignments to it.

Failure

Evaluating the assignable variable list_of_binders never fails.

map2

```
map2 : (((* # **) -> ***) -> (* list # ** list) -> *** list)
```

Synopsis

Maps a binary function over two lists to create one new list.

Description

map2 f ([x1;...;xn],[y1;...;yn]) returns [f(x1,y1);...;f(xn,yn)].

Failure

Fails with map2 if the two lists are of different lengths.

Example

```
#map2 $+ ([1;2;3],[3;2;1]);;
[4; 4; 4] : int list
```

See also

map, uncurry.

mapfilter

mapfilter : ((* -> **) -> * list -> ** list)

Applies a function to every element of a list, returning a list of results for those elements for which application succeeds.

Failure

Never fails.

Example

```
#mapfilter hd [[1;2;3];[4;5];[];[6;7;8];[]];;
[1; 4; 6] : int list
```

See also

filter, map.

MAP_EVERY

MAP_EVERY : ((* -> tactic) -> * list -> tactic)

Synopsis

Sequentially applies all tactics given by mapping a function over a list.

Description

When applied to a tactic-producing function f and an operand list [x1;...;xn], the elements of which have the same type as f's domain type, MAP_EVERY maps the function f over the list, producing a list of tactics, then applies these tactics in sequence as in the case of EVERY. The effect is:

MAP_EVERY f [x1; ...; xn] = (f x1) THEN ... THEN (f xn)

If the operand list is empty, then MAP_EVERY has no effect.

Failure

The application of MAP_EVERY to a function and operand list fails iff the function fails when applied to any element in the list. The resulting tactic fails iff any of the resulting tactics fails.

Example

A convenient way of doing case analysis over several boolean variables is:

```
MAP_EVERY BOOL_CASES_TAC ["var1:bool";...;"varn:bool"]
```

See also

EVERY, FIRST, MAP_FIRST, THEN.

MAP_FIRST

MAP_FIRST : ((* -> tactic) -> * list -> tactic)

Synopsis

Applies first tactic that succeeds in a list given by mapping a function over a list.

Description

When applied to a tactic-producing function f and an operand list [x1;...;xn], the elements of which have the same type as f's domain type, MAP_FIRST maps the function f over the list, producing a list of tactics, then tries applying these tactics to the goal till one succeeds. If f(xm) is the first to succeed, then the overall effect is the same as applying f(xm). Thus:

MAP_FIRST f [x1;...;xn] = (f x1) ORELSE ... ORELSE (f xn)

Failure

The application of MAP_FIRST to a function and tactic list fails iff the function does when applied to any of the elements of the list. The resulting tactic fails iff all the resulting tactics fail when applied to the goal.

See also

EVERY, FIRST, MAP_EVERY, ORELSE.

MATCH_ACCEPT_TAC

MATCH_ACCEPT_TAC : thm_tactic

Solves a goal which is an instance of the supplied theorem.

Description

When given a theorem $A' \mid -t$ and a goal A := t' where t can be matched to t' by instantiating variables which are either free or universally quantified at the outer level, including appropriate type instantiation, MATCH_ACCEPT_TAC completely solves the goal.

```
A ?- t'
====== MATCH_ACCEPT_TAC (A' |- t)
```

Unless A' is a subset of A, this is an invalid tactic.

Failure

Fails unless the theorem has a conclusion which is instantiable to match that of the goal.

Example

The following example shows variable and type instantiation at work. We can use the polymorphic list theorem HD:

HD = |-!h t. HD(CONS h t) = h

to solve the goal:

?-HD[1;2] = 1

simply by:

MATCH_ACCEPT_TAC HD

See also

ACCEPT_TAC.

MATCH_MP

 $MATCH_MP$: (thm -> thm -> thm)

Synopsis

Modus Ponens inference rule with automatic matching.

Description

When applied to theorems A1 |- !x1...xn. t1 ==> t2 and A2 |- t1', the inference rule MATCH_MP matches t1 to t1' by instantiating free or universally quantified variables in the first theorem (only), and returns a theorem A1 u A2 |- !xa..xk. t2', where t2' is a correspondingly instantiated version of t2. Polymorphic types are also instantiated if necessary.

Variables free in the consequent but not the antecedent of the first argument theorem will be replaced by variants if this is necessary to maintain the full generality of the theorem, and any which were universally quantified over in the first argument theorem will be universally quantified over in the result, and in the same order.

A1 |- !x1..xn. t1 ==> t2 A2 |- t1' ----- MATCH_MP A1 u A2 |- !xa..xk. t2'

Failure

Fails unless the first theorem is a (possibly repeatedly universally quantified) implication whose antecedent can be instantiated to match the conclusion of the second theorem, without instantiating any variables which are free in A1, the first theorem's assumption list.

Example

In this example, automatic renaming occurs to maintain the most general form of the theorem, and the variant corresponding to z is universally quantified over, since it was universally quantified over in the first argument theorem.

```
#let ith =
# (GENL ["x:num"; "z:num"] o DISCH_ALL o AP_TERM "$+ (w + z)")
# (ASSUME "x:num = y");;
ith = |- !x z. (x = y) ==> ((w + z) + x = (w + z) + y)
#let th = ASSUME "w:num = z";;
th = w = z |- w = z
#MATCH_MP5 ith th;;
w = z |- !z'. (w' + z') + w = (w' + z') + z
```

See also

EQ_MP, MATCH_MP_TAC, MP, MP_TAC.

MATCH_MP_TAC

MATCH_MP_TAC : thm_tactic

Synopsis

Reduces the goal using a supplied implication, with matching.

Description

When applied to a theorem of the form

A' |- !x1...xn. s ==> !y1...ym. t

MATCH_MP_TAC produces a tactic that reduces a goal whose conclusion t, is a substitution and/or type instance of t to the corresponding instance of s. Any variables free in s but not in t will be existentially quantified in the resulting subgoal:

where z_1 , ..., z_p are (type instances of) those variables among x_1 , ..., x_n that do not occur free in t. Note that this is not a valid tactic unless $A^{,}$ is a subset of A.

Failure

Fails unless the theorem is an (optionally universally quantified) implication whose consequent can be instantiated to match the goal. The generalized variables v1, ..., vi must occur in s' in order for the conclusion t of the supplied theorem to match t'.

See also

EQ_MP, MATCH_MP, MP, MP_TAC.

match_term

```
match_term :
term -> term -> (term,term) subst * (hol_type,hol_type) subst
```

Synopsis

Finds instantiations to match one term to another.

Description

When applied to two terms, match_term attempts to find a set of type and term instantiations for the first term (only) to make it alpha-convertible to the second. If it succeeds, it returns the instantiations in the form of a pair containing a term substitution and a type substitution. If the first term represents the conclusion of a theorem, the returned instantiations are of the appropriate form to be passed to INST_TY_TERM.

Failure

Fails if the term cannot be matched by one-way instantiation.

Example

The following shows how match_term could be used to match the conclusion of a theorem to a term.

Comments

Note that there is no guarantee that the returned instantiations will be possible for INST_TY_TERM to achieve, because some of the variables (term or type) which need to be

instantiated may be free in the assumptions, eg:

In fact, for instantiating a theorem, PART_MATCH is usually easier.

See also

match_type, INST_TY_TERM, PART_MATCH.

match_type

match_type : hol_type -> hol_type -> hol_type subst

Synopsis

Finds a substitution theta such that instantiating the first argument with theta equals the second argument.

Description

If match_type ty1 ty2 succeeds, then

Type.type_subst (match_type ty1 ty2) ty1 = ty2

match_type is not found in hol88.

Failure

It fails if no such substitution can be found.

Example

```
- match_type (==':'a'==) (==':num'==);
> val it =
    [{redex = (==':'a'==), residue = (==':num'==)}] : hol_type subst
- let val patt = ==':('a -> bool) -> 'b'==
= val ty = ==':(num -> bool) -> bool'==
= in
= type_subst (match_type patt ty) patt = ty
= end;
> val it = true : bool
```

See also

match_term

max_print_depth

```
max_print_depth : (int -> int)
```

Synopsis

Sets depth of block nesting.

Description

The function max_print_depth is used to define the maximum depth of nesting that the pretty printer will allow. If the number of blocks is greater than the the value set by max_print_depth then the blocks are truncated and this is indicated by the holophrast &. The function always returns the previous maximum depth setting.

Failure

Never fails.

Example

If the maximum depth setting is the default (500) and we want to change this to 20 the

command will be:

#max_print_depth 20;;

The system will then return the following:

500 : int

See also

print_begin, print_ibegin, print_end, set_margin, print_break

mem

mem : (* -> * list -> bool)

Synopsis

Tests whether a list contains a certain member.

Description

mem x [x1;...;xn] returns true if some xi in the list is equal to x. Otherwise it returns false.

Failure

Never fails.

See also

```
find, tryfind, exists, forall, assoc, rev_assoc.
```

MESON_TAC

mesonLib.MESON_TAC : thm list -> tactic

Synopsis

Performs first order proof search to prove the goal, using the given theorems as additional assumptions in the search.

Description

MESON_TAC performs first order proof using the model elimination algorithm. This algorithm is semi-complete for pure first order logic. It makes special provision for handling polymorphic and higher-order values, and often this is sufficient. It does not handle conditional expressions at all, and these should be eliminated before MESON_TAC is applied.

MESON_TAC works by first converting the problem instance it is given into an internal format where it can do proof search efficiently, without having to do proof search at the level of HOL inference. If a proof is found, this is translated back into applications of HOL inference rules, proving the goal.

The feedback given by MESON_TAC is controlled by the level of the integer reference variable mesonLib.chatting. At level zero, nothing is printed. At the default level of one, a line of dots is printed out as the proof progresses. At all other values for this variable, MESON_TAC is most verbose. If the proof is progressing quickly then it is often worth waiting for it to go quite deep into its search. Once a proof slows down, it is not usually worth waiting for it after it has gone through a few (no more than five or six) levels. (At level one, a "level" is represented by the printing of a single dot.)

Failure

MESON_TAC fails if it searches to a depth equal to the contents of the reference variable mesonLib.max_depth (set to 30 by default, but changeable by the user) without finding a proof. Shouldn't fail otherwise.

Uses

MESON_TAC can only progress the goal to a successful proof of the (whole) goal or not at all. In this respect it differs from tactics such as simplification and rewriting. Its ability to solve existential goals and to make effective use of transitivity theorems make it a particularly powerful tactic.

Comments

The assumptions of a goal are ignored when MESON_TAC is applied. To include assumptions use ASM_MESON_TAC.

See also

ASM_MESON_TAC, GEN_MESON_TAC

mk_abs

mk_abs : {Bvar: term, Body : term} -> term

Constructs an abstraction.

Description

```
mk_abs {Bvar = v, Body = t} returns the abstraction -- '\v. t'--.
```

Failure

Fails with

See also

```
dest_abs, is_abs, list_mk_abs, mk_var, mk_const, mk_comb.
```

MK_ABS

MK_ABS : (thm -> thm)

Synopsis

Abstracts both sides of an equation.

Description

When applied to a theorem A |-!x.t1 = t2, whose conclusion is a universally quantified equation, MK_ABS returns the theorem A |-|x.t1 = |x.t2|.

 $A \mid - !x. t1 = t2$ ----- MK_ABS $A \mid - (\x. t1) = (\x. t2)$

Failure

Fails unless the theorem is a (singly) universally quantified equation.

See also

ABS, HALF_MK_ABS, MK_COMB, MK_EXISTS.

mk_comb

mk_comb : {Rator : term, Rand : term} -> term

Constructs a combination (function application).

Description

mk_comb {Rator = t1, Rand = t2} returns the combination -- 't1 t2'--.

Failure

Fails with

where t1 does not have a function type, orif t1 has a function type, but its domain does not equal the type of t2.

Example

```
- mk_comb{Rator = --'$~'--, Rand = --'T'--};
> val (--'~T'--) : term
- mk_comb{Rator = --'T'--, Rand = --'T'--} handle e => Raise e;
Exception raised at Term.mk_comb:
incompatible types
! Uncaught exception:
! HOL_ERR <poly>
```

See also

dest_comb, is_comb, list_mk_comb, mk_var, mk_const, mk_abs.

MK_COMB

```
MK\_COMB : ((thm # thm) -> thm)
```

Synopsis

Proves equality of combinations constructed from equal functions and operands.

Description

When applied to theorems A1 |-f = g and A2 |-x = y, the inference rule MK_COMB returns the theorem A1 u A2 |-f x = g y.

A1 |-f = g A2 |-x = yA1 u A2 |-f x = g y MK_COMB

Failure

Fails unless both theorems are equational and f and g are functions whose domain types are the same as the types of x and y respectively.

See also

AP_TERM, AP_THM.

mk_cond

mk_cond : {cond :term, larm :term, rarm :term} -> term

Synopsis

Constructs a conditional term.

Description

```
mk_cond{cond = t, larm = t1, rarm = t2} returns --'t => t1 | t2'--.
```

Failure

Fails with

if cond is not of type == ':bool' == or if larm and rarm are of different types.

See also

dest_cond, is_cond.

mk_conj

mk_conj : {conj1 :term, conj2 : term} -> term

mk_cons

Synopsis

Constructs a conjunction.

Description

mk_conj{conj1 = t1, conj2 = t2} returns -- 't1 /\ t2'--.

Failure

Fails with

See also

dest_conj, is_conj, list_mk_conj.

mk_cons

mk_cons : {hd :term, tl :term} -> term

Synopsis

Constructs a CONS pair.

Description

mk_cons{hd = t, tl = --'[t1;...;tn]'--} returns --'[t;t1;...;tn]'--.

Failure

Fails with

if tl is not a list or if hd is not of the same type as the elements of the list.

See also

dest_cons, is_cons, mk_list, dest_list, is_list.

mk_const

mk_const : {Name:string, Ty : hol_type} -> term

Constructs a constant.

Description

```
mk_const{Name = "const", Ty = ty} returns the constant - const:ty-.
```

Failure

Fails with

where message is prefixed with "not in term signature" if the string supplied is not the name of a known constant, or "not a type instance" if the string is known as a constant but the type supplied is not an instance of the declared type of that constant.

Example

```
- mk_const {Name = "T", Ty = ==':bool'==};
> val it = (--'T'--) : term
- Dsyntax.mk_const {Name = "T", Ty = ==':num'==} handle e => Raise e;
Exception raised at Dsyntax.mk_const:
not a type instance: T
- mk_const {Name = "test", Ty = ==':bool'==} handle e => Raise e;
Exception raised at Dsyntax.mk_const:
not in term signature: test
```

See also dest_const, is_const, mk_var, mk_comb, mk_abs.

mk_disj

mk_disj : {disj1 :term, disj2 : term} -> term

Synopsis

Constructs a disjunction.

Description

 $mk_disj{disj1 = t1, disj2 = t2}$ returns -- 't1 \/ t2'--.

Failure

Fails with

See also

dest_disj, is_disj, list_mk_disj.

mk_eq

mk_eq : {lhs : term, rhs: term} -> term

Synopsis

Constructs an equation.

Description

 $mk_eq{lhs = t1, rhs = t2}$ returns -- 't1 = t2'--.

Failure

Fails with

See also

dest_eq, is_eq.

mk_exists

mk_exists : {Bvar : term, Body : term} -> term

Synopsis

Term constructor for existential quantification.

Description

mk_exists{Bvar = v, Body = t} returns -- '?v. t'--.

Failure

Fails with

if Bvar is not a variable or if Body is not of type == ':bool'==.

See also

```
dest_exists, is_exists, list_mk_exists.
```

MK_EXISTS

MK_EXISTS : (thm -> thm)

Synopsis

Existentially quantifies both sides of a universally quantified equational theorem.

Description

When applied to a theorem A |-!x.t1 = t2, the inference rule MK_EXISTS returns the theorem A |-(?x.t1) = (?x.t2).

A |- !x. t1 = t2 ----- MK_EXISTS A |- (?x. t1) = (?x. t2)

Failure

Fails unless the theorem is a singly universally quantified equation.

See also

AP_TERM, EXISTS_EQ, GEN, LIST_MK_EXISTS, MK_ABS.

mk_forall

mk_forall : {Bvar : term, Body : term} -> term

Synopsis

Term constructor for universal quantification.

Description

mk_forall{Bvar = v, Body = t} returns -- '!v. t'--.

Failure

Fails with

if Bvar is not a variable or if Body is not of type == ':bool'==.

See also

```
dest_forall, is_forall, list_mk_forall.
```

mk_imp

mk_imp : {ant : term, conseq : term} -> term

Synopsis

Constructs an implication.

Description

 $mk_imp\{ant = t1, conseq = t2\}$ returns -- 't1 ==> t2'--.

Failure

Fails with

See also

dest_imp, is_imp, list_mk_imp.

mk_let

mk_let : {func : term, arg : term} -> term

Constructs a let term.

Description

mk_let {func = f, arg = x} returns -- 'LET f x'--. If func is of the form -- '\y. t'-- then the result will be pretty-printed as -- 'let y = x in t'--.

Failure

Fails with

if the types of func and arg are such that -- 'LET func arg'-- is not well-typed. -- 'LET'-- has most general type:

==':('a -> 'b) -> 'a -> 'b'==

Example

- mk_let{func = --'\$= 1'--, arg = --'2'--};
> val it = (--'LET (\$= 1) 2'--) : term
- mk_let{func= --'\y. y = 1'--, arg = --'2'--};
> val it = (--'let y = 2 in (y = 1)'--) : term

See also

dest_let, is_let.

mk_list

mk_list : {els : term list, ty : hol_type} -> term

Synopsis

Constructs an object-level (HOL) list from an ML list of terms.

Description

 mk_{list} = [t1, ..., tn], ty = ty} returns -- '[t1;...;tn]:ty list'--. The type argument is required so that empty lists can be constructed.

Failure

Fails with

if any term in the list is not of the type specified as the second argument.

See also dest_list, is_list, mk_cons, dest_cons, is_cons.

mk_neg

mk_neg : (term -> term)

Synopsis

Constructs a negation.

Description

mk_neg "t" returns "~t".

Failure

Fails with mk_neg unless t is of type bool.

See also

dest_neg, is_neg.

mk_pabs

mk_pabs : {varstruct :term, body :term} -> term

Synopsis

Constructs a paired abstraction.

Description

 $mk_pabs \{varstruct = --'(v1, ..(..), vn)'--, body = t\}$ returns the abstraction --' (v1, ..(..))

Failure

Fails unless varstruct is an arbitrarily nested pair composed from variables.

See also

dest_pabs, is_pabs, mk_abs.

mk_pair

mk_pair : {fst :term, snd :term} -> term

Synopsis

Constructs object-level pair from a pair of terms.

Description

mk_pair{fst = t1, snd = t2} returns -- '(t1,t2)'--.

Failure

Never fails.

See also

dest_pair, is_pair, list_mk_pair.

mk_primed_var

mk_primed_var : {Name : string, Ty : hol_type} -> term

Synopsis

Primes a variable name sufficiently to make it distinct from all constants.

Description

When applied to a record made from string "v" and a type ty, the function mk_{primed_var} constructs a variable whose name consists of v followed by however many primes are necessary to make it distinct from any constants in the current theory.

Failure

Never fails.

Example

```
- new_theory "wombat";
> val it = () : unit
- mk_primed_var{Name = "x", Ty = ==':bool'==};
> val it = (--'x'--) : term
- new_constant{Name = "x", Ty = ==':num'==};
> val it = () : unit
- mk_primed_var{Name = "x",Ty = ==':bool'==};
> val it = (--'x''--) : term
```

See also

genvar, variant.

mk_select

mk_select : {Bvar : term, Body : term} -> term

Synopsis

Constructs a choice-term.

Description

mk_select{Bvar = v, Body = t} returns -- '@var. t'--.

Failure

Fails with

if Bvar is not a variable or if Body is not of type == ':bool'==.

See also dest_select, is_select.

mk_simpset

simpLib.mk_simpset : ssdata list -> simpset

Creates a simpset by combining a list of ssdata values.

Failure

Never fails.

Uses

Creates simpsets, which are a necessary argument to any simplification function.

See also

```
++, rewrites, SIMP_CONV
```

mk_thm

```
mk_thm : (((term list # term) -> thm))
```

Synopsis

Creates an arbitrary theorem (dangerous!)

Description

The function mk_thm can be used to construct an arbitrary theorem. It is applied to a pair consisting of the desired assumption list (possibly empty) and conclusion. All the terms therein should be of type bool.

```
mk_thm(["a1";...;"an"],"c") = ({a1,...,an} |- c)
```

Failure

Fails unless all the terms provided for assumptions and conclusion are of type bool.

Example

The following shows how to create a simple contradiction:

```
#mk_thm([],"F");;
|- F
```

Comments

Although mk_thm can be useful for experimentation or temporarily plugging gaps, its use should be avoided if at all possible in important proofs, because it can be used to create

theorems leading to contradictions. The example above is a trivial case, but it is all too easy to create a contradiction by asserting 'obviously sound' theorems.

All theorems which are likely to be needed can be derived using only HOL's inbuilt 5 axioms and 8 primitive inference rules, which are provably sound (see the DESCRIP-TION). Basing all proofs, normally via derived rules and tactics, on just these axioms and inference rules gives proofs which are (apart from bugs in HOL or the underlying system) completely secure. This is one of the great strengths of HOL, and it is foolish to sacrifice it to save a little work.

Note that the system shows the type of mk_thm as (goal -> thm).

See also

new_axiom.

mk_type

```
mk_type : {Tyop :string, Args :hol_type list} -> hol_type
```

Synopsis

Constructs a type (other than a variable type).

Description

mk_type{Tyop = "op", Args = [ty1,...,tyn]} returns

==':(ty1,...,tyn)op'==

where op is the name of a known n-ary type constructor.

Failure

Fails with

```
HOL_ERR{origin_structure = "Dsyntax", origin_function="mk_type", message}
```

where message is "type op not defined", if Tyop is not the name of a known type, or "arities don't match" if the type is known but the length of the list of argument types is not equal to the arity of the type constructor.

Example

```
- mk_type {Tyop = "bool", Args = []};
> val it = (==':bool'==) : hol_type
- mk_type {Tyop = "list", Args = [==':bool'==]};
> val it = (==':bool list'==) : hol_type
- mk_type {Tyop = "fun", Args = [==':num'==, ==':bool'==]};
> val it = (==':num -> bool'==) : hol_type
```

See also

dest_type, mk_vartype.

mk_var

mk_var : {Name:string, Ty: hol_type} -> term

Synopsis

Constructs a variable of given name and type.

Description

mk_var{Name = "var", Ty = ty} returns the variable -- 'var:ty'--.

Failure

Never fails.

Comments

mk_var can be used to construct variables with names which are not acceptable to the term parser. In particular, a variable with the name of a known constant can be constructed using mk_var.

See also

dest_var, is_var, mk_const, mk_comb, mk_abs.

mk_vartype

mk_vartype : (string -> type)

MP

Synopsis

Constructs a type variable of the given name.

Description

mk_vartype('*...') returns ":*...".

Failure

Fails with mk_vartype if the string does not begin with '*'.

Example

```
#mk_vartype '*test';;
":*test" : type
#mk_vartype 'test';;
evaluation failed mk_vartype
```

Comments

mk_vartype can be used to create type variables with names which will not parse, i.e. they cannot be entered by quotation.

See also

dest_vartype, is_vartype, mk_type.

MP

```
\mbox{MP} : (thm -> thm -> thm)
```

Synopsis

Implements the Modus Ponens inference rule.

Description

When applied to theorems A1 |-t1 => t2 and A2 |-t1, the inference rule MP returns the theorem A1 u A2 |-t2.

A1 |- t1 ==> t2 A2 |- t1 ----- MP A1 u A2 |- t2

Failure

Fails unless the first theorem is an implication whose antecedent is the same as the conclusion of the second theorem (up to alpha-conversion).

See also

EQ_MP, LIST_MP, MATCH_MP, MATCH_MP_TAC, MP_TAC.

MP_TAC

MP_TAC : thm_tactic

Synopsis

Reduces a goal to implication from a known theorem.

Description

When applied to the theorem A' \mid s and the goal A ?- t, the tactic MP_TAC reduces the goal to A ?- s ==> t. Unless A' is a subset of A, this is an invalid tactic.

A ?- t =========== MP_TAC (A' |- s) A ?- s ==> t

Failure

Never fails.

See also

MATCH_MP_TAC, MP, UNDISCH_TAC.

NEG_DISCH

NEG_DISCH : (term \rightarrow thm \rightarrow thm)

Synopsis

Discharges an assumption, transforming |-s => F into |-s.

Description

When applied to a term s and a theorem $A \mid -t$, the inference rule NEG_DISCH returns the theorem $A - \{s\} \mid -s => t$, or if t is just F, returns the theorem $A - \{s\} \mid -s$.

A |- F ----- NEG_DISCH [special case] A - {s} |- ~s A |- t A - {s} |- s ==> t [general case]

Failure

Fails unless the supplied term has type bool.

See also

DISCH, NOT_ELIM, NOT_INTRO.

new_axiom

Compat.new_axiom : (string * term) -> thm

Synopsis

Sets up a new axiom in the current theory.

Description

Found in the hol88 library. If tm is a term of type bool, a call new_axiom("name",tm) creates a theorem

|- !x1..xn. tm

and stores it away in the theory file. Note that all free variables in tm are generalized automatically before the axiom is set up.

Failure

Fails if HOL is not in draft mode, or there is already an axiom or definition of that name in the current theory, or it the given term does not have type bool. The function will not be available unless the hol88 library is loaded.

Example

```
- new_theory "gurk";
() : unit
- new_axiom("untrue",--'x = 1'--));
|- !x. x = 1
```

Comments

hol90 doesn't have new_axiom; use new_open_axiom instead, which does not automatically generalize the term being asserted as an axiom. For most purposes, it is unnecessary to declare new axioms: all of classical mathematics can be derived by definitional extension alone. Proceeding by definition is not only more elegant, but also guarantees the consistency of the deductions made. However, there are certain entities which cannot be modelled in simple type theory without further axioms, such as higher transfinite ordinals.

See also

mk_thm, new_definition.

new_binder

new_binder : {Name :string, Ty :hol_type} -> unit

Synopsis

Sets up a new binder in the current theory.

Description

A call new_binder{Name ="bnd",Ty = ty} declares a new binder bnd in the current theory. The type must be of the form ('a -> 'b) -> 'c, because being a binder, bnd will apply to an abstraction; for example

```
---'!x:bool. (x=T) \/ (x=F)'--
is actually a prettyprinting of
---'$! (\x. (x=T) \/ (x=F))'--.
```

Failure

Fails if HOL is not in draft mode, or there is already a constant of some sort of that name in the current theory, or if the type does not correspond to the above pattern.

Example

```
- new_theory "anorak";
() : unit
- new_binder{Name = "!!", Ty = ==':(bool->bool)->bool'==};
() : unit
- --'!!x. T'--;
(--'!! x. T'--) : term
```

See also

binders, is_binder, constants, infixes, new_constant, new_infix, new_definition, new_infix_definition, new_binder_definition.

new_binder_definition

new_binder_definition : ((string # term) -> thm)

Synopsis

Defines a new constant, giving it the syntactic status of a binder.

Description

The function new_binder_definition provides a facility for making definitional extensions to the current theory by introducing a constant definition. It takes a pair of arguments, consisting of the name under which the resulting theorem will be saved in the current theory segment and a term giving the desired definition. The value returned by new_binder_definition is a theorem which states the definition requested by the user.

Let v1, ..., vn be syntactically distinct tuples constructed from the variables x1,..., xm. A binder is defined by evaluating

```
new_binder_definition ('name', "b v1 ... vn = t")
```

where b is not already a constant, b does not occur in t, all the free variables that occur in t are a subset of $x1, \ldots, xn$, and the type of b has the form '(ty1->ty2)->ty3'. This declares b to be a new constant with the syntactic status of a binder in the current theory, and with the definitional theorem

|-!x1...xn. b v1 ... vn = t

as its specification. This constant specification for b is saved in the current theory under the name name and is returned as a theorem. The equation supplied to new_binder_definition may optionally have any of its free variables universally quantified at the outermost level. The constant b has binder status only after the definition has been made.

Failure

new_binder_definition fails if called when HOL is not in draft mode. It also fails if there is already an axiom, definition or specification with the given name in the current theory segment, if 'b' is already a constant in the current theory or is not an allowed name for a constant, if t contains free variables that are not in any one of the variable structures v1, ..., vn or if any variable occurs more than once in v1, ..., v2. Failure also occurs if the type of b is not of the form appropriate for a binder, namely a type of teh form '(ty1->ty2)->ty3'. Finally, failure occurs if there is a type variable in v1, ..., vn or t that does not occur in the type of b.

Example

The unique-existence quantifier ?! is defined as follows.

```
#new_binder_definition
  ('EXISTS_UNIQUE_DEF',
    "$?! = \P:(*->bool). ($? P) /\ (!x y. ((P x) /\ (P y)) ==> (x=y))");;
|- $?! = (\P. $? P /\ (!x y. P x /\ P y ==> (x = y)))
```

Comments

It is a common practice among HOL users to write a \$ before the constant being defined as a binder to indicate that it will have a special syntactic status after the definition is made:

```
new_binder_definition('name', "$b = ... ");;
```

This use of \$ is not necessary; but after the definition has been made \$ must, of course, be used if the syntactic status of b needs to be suppressed.

new_infix_list_rec_definition, new_prim_rec_definition,
new_list_rec_definition, new_prim_rec_definition.
```

new_constant

new_constant : {Name :string, Ty :hol_type} -> unit

Declares a new constant in the current theory.

Description

A call new_constant{Name="c", Ty = ty} makes c a constant in the current theory. Note that it does not specify its value. The constant may have a polymorphic type, which can be used in arbitrary instantiations.

Failure

Fails if HOL is not in draft mode, or if the name is not a valid constant name, or there is already a constant of that name in the current theory.

Example

```
- new_theory "zonk";
() : unit
- new_constant{Name = "graham's_number", Ty = ==':num'==};
() : unit
```

See also

constants, infixes, binders, is_constant, is_infix, is_binder, new_infix, new_binder, new_definition, new_infix_definition, new_binder_definition.

new_definition

```
new_definition : ((string # term) -> thm)
```

Synopsis

Declare a new constant and install a definitional axiom in the current theory.

Description

The function new_definition provides a facility for definitional extensions to the current theory. It takes a pair argument consisting of the name under which the resulting definition will be saved in the current theory segment, and a term giving the desired definition. The value returned by new_definition is a theorem which states the definition requested by the user.

Let $v_1,...,v_n$ be tuples of distinct variables, containing the variables $x_1,...,x_m$. Evaluating new_definition ('name', "c v_1 ... $v_n = t$ "), where c is not already a constant, declares the sequent $({},"\v_1 \dots v_n, t")$ to be a definition in the current theory, and declares c to be a new constant in the current theory with this definition as its specification. This constant specification is returned as a theorem with the form

```
| - !x_1 \dots x_m \dots c v_1 \dots v_n = t
```

and is saved in the current theory under (the name) name. Optionally, the definitional term argument may have any of its variables universally quantified.

Failure

new_definition fails if called when HOL is not in draft mode. It also fails if there is already an axiom, definition or specification of the given name in the current theory segment; if 'c' is already a constant in the current theory or is not an allowed name for a constant; if t contains free variables that are not in any of the variable structures $v_1, ..., v_n$ (this is equivalent to requiring $v_1 ... v_n$. t to be a closed term); or if any variable occurs more than once in $v_1, ..., v_n$. Finally, failure occurs if there is a type variable in $v_1, ..., v_n$ or t that does not occur in the type of c.

Example

A NAND relation can be defined as follows.

```
- new_definition (
    "NAND2",
    Term'NAND2 (in_1,in_2) out = !t:num. out t = ~(in_1 t /\ in_2 t)');
> val it =
    |- !in_1 in_2 out.
        NAND2 (in_1,in_2) out = !t. out t = ~(in_1 t /\ in_2 t)
    : Thm.thm
```

new_gen_definition

Parse.new_gen_definition : (string * term * fixity) -> thm

Synopsis

Defines a new constant and associates it with a parsing fixity.

Description

The function new_gen_definition provides a facility for definitional extensions to the current theory. It takes a tuple of three arguments. The first component of this tuple is the name under which the resulting definition will be saved in the current theory segment. The second component is a term giving the desired definition. The third component is a fixity (typically one of Binder, Infixl n, Infixr n, Suffix n, TruePrefix n or Closefix). The value returned by new_gen_definition is a theorem which states the definition requested by the user.

Let $v_1,...,v_n$ be tuples of distinct variables, containing the variables $x_1,...,x_m$. Evaluating new_gen_definition flag ('name', "c $v_1 ... v_n = t$ "), where c is not already a constant, declares the sequent ({},"\v_1 ... v_n. t") to be a definition in the current theory, and declares c to be a new constant in the current theory with this definition as its specification. This constant specification is returned as a theorem, generally of the form $|-!x_1 ... x_m. c v_1 ... v_n = t$, and is saved in the current theory under (the name) name. If flag is 'infix' or 'binder', the constant is given infix or binder status accordingly. Optionally, the definitional term argument may have any of its variables universally quantified.

Failure

new_gen_definition fails if there is already an axiom, definition or specification of the given name in an ancestral theory segment; if c is not an allowed name for a constant; if t contains free variables that are not in any of the variable structures $v_1, ..., v_n$ (this is equivalent to requiring $v_1 ..., v_n$. t to be a closed term); or if any variable occurs more than once in $v_1, ..., v_n$. Finally, failure occurs if there is a type variable in $v_1, ..., v_n$ or t that does not occur in the type of c.

DEF_EXISTS_RULE, new_binder_definition, new_definition, new_infix_definition, new_specification.

new_infix

new_infix : {Name :string, Ty :hol_type, Prec :int} -> unit

Synopsis

Declares a new infix constant in the current theory.

Description

A call $new_infix{Name = "i", Ty = ty, Prec = n}$ makes i a right associative infix constant in the current theory. It has binding strength of n, the larger this number,

the more tightly the infix will attempt to "grab" arguments to its left and right. Note that the call to new_infix does not specify the value of the constant. The constant may have a polymorphic type, which may be arbitrarily instantiated. Like any other infix or binder, its special parse status may be suppressed by preceding it with a dollar sign.

Comments

Infixes defined with new_infix associate to the right, i.e., A < op > B < op > C is equivalent to $A \circ p$ (B < op > C). The initial infixes (and their precedences) in the system are:

>	50
>	100
>	200
>	300
>	400
>	450
>	450
>	500
>	600
>	650
>	700
>	800
	> > > > >

Note that the arithmetic operators +, -, *, DIV and MOD are left associative in hol98 releases from Taupo onwards.

Failure

Fails if the name is not a valid constant name.

Example

The following shows the use of the infix and the prefix form of an infix constant. It also

shows binding resolution between infixes of different precedence.

See also

add_infix, precedence, constants, infixes, binders, is_constant, is_infix, is_binder, new_constant, new_binder, new_definition, new_infix_definition, new_binder_definition.

new_infixl_definition

Parse.new_infixl_definition : (string * term * int) -> thm

Synopsis

Declares a new left associative infix constant and installs a definition in the current theory.

Description

The function new_infix_definition provides a facility for definitional extensions to the current theory. It takes a triple consisting of the name under which the resulting definition will be saved in the current theory segment, a term giving the desired definition and an integer giving the precedence of the infix. The value returned by new_infix_definition is a theorem which states the definition requested by the user.

Let v_1 and v_2 be tuples of distinct variables, containing the variables x_1, \ldots, x_m . Evaluating new_infix_definition ('name', "ix v_1 v_2 = t"), where ix is not already a constant, declares the sequent ({},"\v_1 v_2. t") to be a definition in the current theory, and declares ix to be a new constant in the current theory with this definition as its specification. This constant specification is returned as a theorem with the form

```
|-!x_1 \dots x_m \dots v_1 \text{ ix } v_2 = t
```

and is saved in the current theory under (the name) name. Optionally, the definitional term argument may have any of its variables universally quantified. The constant ix has infix status only after the infix declaration has been processed. It is therefore necessary to use the constant in normal prefix position when making the definition.

Failure

new_infixl_definition fails if there is already an axiom, definition or specification of the given name in an ancestral theory segment; if 'ix' is not an allowed name for a constant; if t contains free variables that are not in either of the variable structures v_1 and v_2 (this is equivalent to requiring $v_1 v_2$. t to be a closed term); or if any variable occurs more than once in v_1 , v_2 . It also fails if the precedence level chosen for the infix is already home to parsing rules of a different form of fixity (infixes associating in a different way, or suffixes, prefixes etc). Finally, failure occurs if there is a type variable in v_1 , ..., v_n or t that does not occur in the type of ix.

Example

The nand function can be defined as follows.

```
- new_infix_definition
  ("nand", --'$nand in_1 in_2 = ~(in_1 /\ in_2)'--, 500);;
> val it = |- !in_1 in_2. in_1 nand in_2 = ~(in_1 /\ in_2) : thm
```

Comments

It is a common practice among HOL users to write a \$ before the constant being defined as an infix to indicate that after the definition is made, it will have a special syntactic status; ie. to write:

```
new_infixl_definition('ix_DEF', "$ix m n = ... ")
```

This use of \$ is not necessary; but after the definition has been made \$ must, of course, be used if the syntactic status needs to be suppressed.

In releases of hol98 past Taupo 1, new_infixl_definition and its sister new_infixr_definition replace the old new_infix_definition, which has been superseded. Its behaviour was to define a right associative infix, so can be freely replaced by new_infixr_definition.

See also

```
new_binder_definition, new_definition, new_gen_definition,
new_infixr_definition, new_infix_list_rec_definition, new_prim_rec_definition,
new_list_rec_definition, new_prim_rec_definition.
```

new_infixr_definition

Parse.new_infixr_definition : (string * term * int) -> thm

Synopsis

Declares a new right associative infix constant and installs a definition in the current theory.

Description

The function new_infixr_definition has exactly the same effect as new_infixl_definition except that the infix constant defined will associate to the right.

Failure

new_infixr_definition fails if there is already an axiom, definition or specification of the given name in an ancestral theory segment; if 'ix' is not an allowed name for a constant; if t contains free variables that are not in either of the variable structures v_1 and v_2 (this is equivalent to requiring $v_1 v_2$. t to be a closed term); or if any variable occurs more than once in v_1 , v_2 . It also fails if the precedence level chosen for the infix is already home to parsing rules of a different form of fixity (infixes associating in a different way, or suffixes, prefixes etc). Finally, failure occurs if there is a type variable in v_1 , ..., v_n or t that does not occur in the type of ix.

new_definition, new_infix, new_infixl_definition

new_infix_prim_rec_definition

Compat.new_infix_prim_rec_definition : (string * term) -> thm

Synopsis

Defines an infix primitive recursive function over the type num.

Description

Found in the hol88 library. The function new_infix_prim_rec_definition provides the facility for defining primitive recursive functions with infix status on the type num. It takes a pair argument, consisting of the name under which the resulting definition will

be saved in the current theory segment, and a term giving the desired definition. The value returned by new_infix_prim_rec_definition is a theorem which states the definition requested by the user. This theorem is derived by formal proof from an instance of the theorem num_Axiom:

|-!e f. ?! fn. (fn 0 = e) / (!n. fn(SUC n) = f(fn n)n)

Evaluating

```
new_infix_prim_rec_definition
 ("fun_DEF",
    (-- '(fun 0 x = f_1[x]) /\
        (fun (SUC n) x = f_2[fun n x', n, x])'--));;
```

where all the free variables in the term x' are contained in $\{n, x\}$, automatically proves the theorem:

|- ?fun. !x. fun 0 x = f_1[x] /\
 !x. fun (SUC n) x = f_2[fun n x', n, x]

and then declares a new constant fun with this property and infix status as its specification. This constant specification is returned as a theorem and is saved with name fun_DEF in the current theory segment.

The ML function new_infix_prim_rec_definition is, in fact, slightly more general than is indicated above. In particular, a curried primitive recursive function can be defined by primitive recursion on either one of its arguments using this ML function. The ML function new_infix_prim_rec_definition also allows the user to partially specify the value of a function defined (possibly recursively) on the natural numbers by giving its value for only one of 0 or SUC n.

Failure

Failure occurs if HOL cannot prove there is a function satisfying the specification (ie. if the term supplied to $new_prim_rec_definition$ is not a well-formed primitive recursive definition); if the type of fun is not of the form $ty_1->ty_2->ty_3$, or if any other condition for making a constant specification is violated (see the failure conditions for $new_specification$). The function will not be accessible unless the hol88 library has been loaded.

Example

Here is the recursive definition of the constant + used by the system:

new_infix_prim_rec_definition
 ("ADD",
 (--((\$+ 0 n = n) /\
 (\$+ (SUC m) n = SUC(\$+ m n))'--))

The \$'s are there (as documentation) to indicate that the constant + is being declared to be an infix. Evaluating this ML expression will create the following constant specification in the current theory segment:

ADD = |-(!n. 0 + n = n) / (!m n. (SUC m) + n = SUC(m + n))

Comments

new_infix_prim_rec_definition is not in hol90; it has been superceded by new_recursive_definit.

```
new_definition, new_infix_definition, new_infix_list_rec_definition,
new_prim_rec_definition, new_list_rec_definition, new_recursive_definition,
new_type_definition, new_specification, num_Axiom.
```

new_list_rec_definition

new_list_rec_definition : ((string # term) -> thm)

Synopsis

Defines a primitive recursive function over the type of lists.

Description

The function new_list_rec_definition provides the facility for defining primitive recursive functions on the type of lists. It takes a pair argument, consisting of the name under which the resulting definition will be saved in the current theory segment, and a term giving the desired definition. The value returned by new_list_rec_definition is a theorem which states the definition requested by the user. This theorem is derived by formal proof from an instance of the theorem list_Axiom:

|-!x f. ?! fn. (fn[] = x) / (!h t. fn(CONS h t) = f(fn t)h t)

Evaluating

where all the free variables in the terms $t_1, ..., t_i$ are contained in {h,t,x_1,...,x_i}, automatically proves the theorem:

and then declares a new constant fun with this property as its specification. This constant specification is returned as a theorem by new_list_rec_definition and is saved with name fun_DEF in the current theory segment.

The ML function new_list_rec_definition also allows the user to partially specify the value of a function defined (possibly recursively) on lists by giving its value for only one of [] or CONS h t. See the examples below.

Failure

Failure occurs if HOL cannot prove there is a function satisfying the specification (ie. if the term supplied to mlnew_list_rec_definition is not a well-formed primitive recursive definition), or if any other condition for making a constant specification is violated (see the failure conditions for new_specification).

Example

The HOL system defines a length function, LENGTH, on lists by the primitive recursive definition on lists shown below:

```
new_list_rec_definition
 ('LENGTH',
 "(LENGTH NIL = 0) /\
 (!h:*. !t. LENGTH (CONS h t) = SUC (LENGTH t))")
```

When this ML expression is evaluated, HOL uses list_Axiom to prove existence of a function that satisfies the given primitive recursive definition, introduces a constant to

name this function using a constant specification, and stores the resulting theorem:

```
LENGTH |- (LENGTH[] = 0) /\ (!h t. LENGTH(CONS h t) = SUC(LENGTH t))
```

in the current theory segment (in this case, the theory list).

Using new_list_rec_definition, the predicate NULL and the selectors HD and TL are defined in the theory list by the specifications:

```
NULL |- NULL[] /\ (!h t. ~NULL(CONS h t))
HD |- !(h:*) t. HD(CONS h t) = h
TL |- !(h:*) t. TL(CONS h t) = t
```

See also

```
new_definition, new_infix_definition, new_infix_list_rec_definition,
new_infix_prim_rec_definition, new_prim_rec_definition,
new_recursive_definition, new_type_definition, new_specification, list_Axiom.
```

new_axiom

new_open_axiom : (string * term) -> thm

Synopsis

Sets up a new axiom in the current theory.

Description

If tm is a term of type bool, a call new_open_axiom("name",tm) creates a theorem

|- tm

and stores it away in the current theory.

Failure

Fails if HOL is not in draft mode, or there is already an axiom or definition of that name in the current theory, or it the given term does not have type bool.

Example

```
- new_theory "gurk";
() : unit
- new_axiom("untrue",--'x = 1'--));
|- x = 1
```

Comments

For most purposes, it is unnecessary to declare new axioms: all of classical mathematics can be derived by definitional extension alone. Proceeding by definition is not only more elegant, but also guarantees the consistency of the deductions made. However, there are certain entities which cannot be modelled in simple type theory without further axioms, such as higher transfinite ordinals.

See also

mk_thm, new_definition.

new_prim_rec_definition

Compat.new_prim_rec_definition : (string * term) -> thm

Synopsis

Define a primitive recursive function over the type :num.

Description

Found in the hol88 library. The function new_prim_rec_definition provides the facility for defining primitive recursive functions on the type num. It takes a pair argument, consisting of the name under which the resulting definition will be saved in the current theory segment, and a term giving the desired definition. The value returned by new_prim_rec_definition is a theorem which states the definition requested by the user. This theorem is derived by formal proof from an instance of the theorem num_Axiom:

|-!e f. ?! fn. (fn 0 = e) / (!n. fn(SUC n) = f(fn n)n)

Evaluating

where all the free variables in the terms $t_1, ..., t_i$ are contained in $\{n, x_1, ..., x_i\}$, automatically proves the theorem:

and then declares a new constant fun with this property as its specification. This constant specification is returned as a theorem by new_prim_rec_definition and is saved with name fun_DEF in the current theory segment.

The ML function new_prim_rec_definition also allows the user to partially specify the value of a function defined (possibly recursively) on the natural numbers by giving its value for only one of 0 or SUC n. See the example below.

Failure

Failure occurs if HOL cannot prove there is a function satisfying the specification (ie. if the term supplied to new_prim_rec_definition is not a well-formed primitive recursive definition), or if any other condition for making a constant specification is violated (see the failure conditions for new_specification). The function will not be available unless the hol88 library has been loaded.

Example

A curried addition function plus:num->num can be defined by primitive recursion

on its first argument:

or by primitive recursion on its second argument:

```
- val PLUS = new_prim_rec_definition
= ('PLUS',
= (--'(plus m 0 = m) /\
= (plus m (SUC n) = SUC(plus m n))'--));
PLUS = |- (!m. plus m 0 = m) /\ (!m n. plus m(SUC n) = SUC(plus m n))
```

A decrement function DEC, whose value is specified for only positive natural numbers, can be defined using new_prim_rec_definition as follows

```
- val DEC = new_prim_rec_definition
= ('DEC', (--'DEC (SUC n) = n'--));
DEC = |- !n. DEC(SUC n) = n
```

This definition specifies the value of the function DEC only for positive natural numbers. In particular, the value of DEC 0 is left unspecified, and the only non-trivial property that can be proved to hold of the constant DEC is the property stated by the theorem returned by the call to new_prim_rec_definition shown in the session above.

Comments

new_prim_rec_definition is not in hol90; it has been superceded by new_recursive_definition.

See also

new_definition, new_infix_definition, new_infix_list_rec_definition, new_infix_prim_rec_definition, new_list_rec_definition, new_recursive_definition, new_type_definition, new_specification, num_Axiom.

new_recursive_definition

new_recursive_definition :
{name:string,def:term,fixity:fixity,rec_axiom:thm} -> thm

Synopsis

Defines a primitive recursive function over a concrete recursive type.

Description

new_recursive_definition provides the facility for defining primitive recursive functions on arbitrary concrete recursive types. name is a name under which the resulting definition will be saved in the current theory segment. def is a term giving the desired primitive recursive function definition. fixity is a value of type :fixity which indicates whether the defined function will be a prefix, binder, or infix. rec_axiom is the primitive recursion theorem for the concrete type in question; this must be a theorem obtained from define_type. The value returned by new_recursive_definition is a theorem which states the primitive recursive definition requested by the user. This theorem is derived by formal proof from an instance of the general primitive recursion theorem given as the second argument.

A theorem th of the form returned by define_type is a primitive recursion theorem for an automatically-defined concrete type ty. Let C1, ..., Cn be the constructors of this type, and let '(Ci vs)' represent a (curried) application of the ith constructor to a sequence of variables. Then a curried primitive recursive function fn over ty can be specified by a conjunction of (optionally universally-quantified) clauses of the form:

where the variables v1, ..., vm, vs are distinct in each clause, and where in the ith clause fn appears (free) in bodyi only as part of an application of the form:

"fn t1 ... v ... tm"

in which the variable v of type ty also occurs among the variables vsi.

If tm is a conjunction of clauses, as described above, then evaluating:

```
new_recursive_definition{name="name", fixity=f, rec_axiom=th,def=tm}
```

automatically proves the existence of a function fn that satisfies the defining equations supplied as the fourth argument, and then declares a new constant in the current theory with this definition as its specification. This constant specification is returned as a theorem and is saved in the current theory segment under the name name. The constant is given the parsing status defined by f (one of Prefix, Infix iint¿, or Binder).

new_recursive_definition also allows the supplied definition to omit clauses for any number of constructors. If a defining equation for the ith constructor is omitted, then the value of fn at that constructor:

fn v1 ... (Ci vsi) ... vn

is left unspecified (fn, however, is still a total function).

Failure

A call to new_recursive_definition fails if the supplied theorem is not a primitive recursion theorem of the form returned by define_type; if the term argument supplied is not a well-formed primitive recursive definition; or if any other condition for making a constant specification is violated (see the failure conditions for new_specification).

Example

Given the following primitive recursion theorem for labelled binary trees:

```
|- !f0 f1.
    ?! fn.
    (!x. fn(LEAF x) = f0 x) /\
    (!b1 b2. fn(NODE b1 b2) = f1(fn b1)(fn b2)b1 b2)
```

new_recursive_definition can be used to define primitive recursive functions over binary trees. Suppose the value of th is this theorem. Then a recursive function Leaves, which computes the number of leaves in a binary tree, can be defined recursively as shown below:

```
- val Leaves = new_recursive_definition
= {name = "Leaves",
= fixity = Prefix,
= rec_axiom = th,
= def= -- (Leaves (LEAF (x:'a)) = 1) /\
= (Leaves (NODE t1 t2) = (Leaves t1) + (Leaves t2))'--};
Leaves =
|- (!x. Leaves(LEAF x) = 1) /\
(!t1 t2. Leaves(NODE t1 t2) = (Leaves t1) + (Leaves t2))
```

The result is a theorem which states that the constant Leaves satisfies the primitiverecursive defining equations supplied by the user.

The function defined using new_recursive_definition need not, in fact, be recursive. Here is the definition of a predicate IsLeaf, which is true of binary trees which are leaves, but is false of the internal nodes in a binary tree:

```
- val IsLeaf = new_recursive_definition
= {name = "IsLeaf",
= fixity = Prefix,
= rec_axiom = th,
= def = --'(IsLeaf (NODE t1 t2) = F) /\
= (IsLeaf (LEAF (x:'a)) = T)'--};
IsLeaf = |- (!t1 t2. IsLeaf(NODE t1 t2) = F) /\ (!x. IsLeaf(LEAF x) = T)
```

Note that the equations defining a (recursive or non-recursive) function on binary trees by cases can be given in either order. Here, the NODE case is given first, and the LEAF case second. The reverse order was used in the above definition of Leaves.

new_recursive_definition also allows the user to partially specify the value of a function defined on a concrete type, by allowing defining equations for some of the constructors to be omitted. Here, for example, is the definition of a function Label which extracts the label from a leaf node. The value of Label applied to an internal node is left unspecified:

```
- val Label = new_recursive_definition
= {name = "Label",
= fixity = Prefix,
= rec_axiom = th,
= def = --'Label (LEAF (x:'a)) = x'--};
Label = |- !x. Label(LEAF x) = x
```

Curried functions can also be defined, and the recursion can be on any argument. The next definition defines an infix function << which expresses the idea that one tree is a proper subtree of another.

```
- val Subtree = new_recursive_definition
         {name = "Subtree",
=
          fixity = Infix 120,
=
          rec_axiom = th,
=
          def = --'(<< (t:'a bintree) (LEAF (x:'a)) = F) /\
=
                    (<< t (NODE t1 t2) = (t = t1) \/</pre>
=
                                          (t = t2) \/
                                          (<< t t1) \/
                                          (<< t t2))'--};</pre>
Subtree =
|-(!t x. t << (LEAF x) = F) / 
   (!t t1 t2.
     t << (NODE t1 t2) = (t = t1) \/ (t = t2) \/ (t << t1) \/ (t << t2))
```

Note that the constant << is an infix only after the definition has been made. Furthermore, the function << is recursive on its second argument.

define_type, prove_rec_fn_exists.

new_specification

```
new_specification :
{name:string, sat_thm:thm,
   consts:{const_name:string, fixity:fixity} list} -> thm
```

Synopsis

Introduces a constant or constants satisfying a given property.

Description

The ML function new_specification implements the primitive rule of constant specification for the HOL logic. Evaluating:

simultaneously introduces new constants named c1, ..., cn satisfying the property:

|- t[c1,...,cn/x1,...,xn]

This theorem is stored, with name name, as a definition in the current theory segment. It is also returned by the call to new_specification The fixities f1, ..., fn are values which determine whether the new constants are infixes or binders or neither. If fi is Prefix then ci is declared an ordinary constant, if it is Infix i then ci is declared an infix with precedence i, and if it is Binder then ci is declared a binder.

Failure

new_specification fails if called when HOL is not in draft mode. It also fails if there is already an axiom, definition or specification of the given name in the current theory segment; if the theorem argument has assumptions or free variables; if the supplied constant names 'c1', ..., 'cn' are not distinct; if any one of 'c1', ..., 'cn' is already a constant in the current theory or is not an allowed name for a constant. Failure also occurs if the type of ci is not suitable for a constant with the syntactic status specified by the fixity fi. Finally, failure occurs if some ci does not contain all the type variables that occur in the term ?x1...xn. t.

Uses

new_specification can be used to introduce constants that satisfy a given property without having to make explicit equational constant definitions for them. For example, the built-in constants MOD and DIV are defined in the system by first proving the theorem:

```
th |- ?MOD DIV.
    !n. (0 < n) ==>
    !k. ((k = (((DIV k n) * n) + (MOD k n))) /\ ((MOD k n) < n))</pre>
```

and then making the constant specification:

This introduces the constants MOD and DIV with the defining property shown above.

See also

new_definition, new_binder_definition, new_gen_definition, new_infix_definition.

new_theory

new_theory : (string -> void)

Synopsis

Creates a new theory by extending the current theory with a new theory segment.

Description

A theory consists of a hierarchy of named parts called theory segments. The theory segment at the top of the hierarchy tree in each theory is said to be current. All theory segments have a theory of the same name associated with them consisting of the theory segment itself and all its ancestors. Each axiom, definition, specification and theorem belongs to a particular theory segment.

Calling new_theory 'thy' creates a new theory segment and associated theory having name thy. The theory segment which was current before the call becomes a parent of the new theory segment. The new theory therefore consists of the current theory

extended with the new theory segment. The new theory segment replaces its parent as the current theory segment. The call switches the system into draft mode. This allows new axioms, constants, types, constant specifications, infix constants, binders and parents to be added to the theory segment. Inconsistencies will be introduced into the theory if inconsistent axioms are asserted. New theorems can also be added as when in proof mode. The theory file in which the data of the new theory segment is ultimately stored will have name thy.th in the directory from which HOL was called. The theory segment might not be written to this file until the session is finished with a call to close_theory. If HOL is quitted without closing the session with close_theory, parts of the theory segment created during the session may be lost. If the system is in draft mode when a call to new_theory is made, the previous session is closed; all changes made in it will be written to the associated theory file.

Failure

The call new_theory 'thy' will fail if there already exists a file thy.th in the current search path. It will also fail if the name thy.th is unsuitable for a filename. Since it could involve writing to the file system, if a write fails for any reason new_theory will fail.

Uses

Hierarchically extending the current theory. By splitting a theory into theory segments using new_theory, the work required if definitions, etc., need to be changed is minimized. Only the associated segment and its descendants need be redefined.

new_specification, new_type, print_theory, save_thm, search_path.
```

new_type

new_type : {Name :string, Arity :int} -> unit

Synopsis

Declares a new type or type constructor.

Description

A call new_type{Name = "t", Arity = n} declares a new n-ary type constructor called t in the current theory segment. If n is zero, this is just a new base type.

Failure

Fails if HOL is not in draft mode, or if the name is not a valid type name, or there is already a type operator of that name in the current theory.

Example

A non-definitional version of ZF set theory might declare a new type set and start using it as follows:

```
- new_theory 'ZF';;
() : unit
- new_type{Name="set", Arity=0};
() : unit
- new_infix{Name="mem",Ty = ==':set->set->bool'==};
() : unit
- new_open_axiom("ext", --'(!z. z mem x = z mem y) ==> (x = y)'--);
|- (!z. z mem x = z mem y) ==> (x = y)
```

See also

types, type_abbrevs, new_type_abbrev.

new_type_definition

new_type_definition : {name :string, pred :term, inhab_thm} -> thm

Synopsis

Defines a new type constant or type operator.

Description

The ML function new_type_definition implements the primitive HOL rule of definition for introducing new type constants or type operators into the logic. If "t" is a term of type ty->bool containing n distinct type variables, then evaluating:

```
new_type_definition{name = "op", pred = "t", inhab_thm = |- ?x. t x}
```

results in op being declared as a new n-ary type operator in the current theory and returned by the call to new_type_definition. This new type operator is characterized by

a definitional axiom of the form:

|- ?rep:('a,...,'n)op->ty. TYPE_DEFINITION t rep

which is stored as a definition in the current theory segment under the automaticallygenerated name 'op_TY_DEF'. The constant TYPE_DEFINITION in this axiomatic characterization of op is defined by:

```
|- TYPE_DEFINITION (P:'a->bool) (rep:'b->'a) =
    (!x' x''. (rep x' = rep x'') ==> (x' = x'')) /\
    (!x. P x = (?x'. x = rep x'))
```

Thus $|-?rep. TYPE_DEFINITION P rep asserts that there is a bijection between the newly defined type ('a,...,'n)op and the set of values of type ty that satisfy P.$

Failure

Executing new_type_definition{name="op",pred="t",inhab_thm=th} fails if op is already the name of a type or type operator in the current theory, if "t" does not have a type of the form ty->bool or th is not an assumption-free theorem of the form |- ?x. t x, if there already exists a constant definition, constant specification, type definition or axiom named op_TY_DEF in the current theory segment, or if HOL is not in draft mode.

NOT_ELIM

NOT_ELIM : (thm -> thm)

Synopsis

Transforms |- "t into |- t => F.

Description

When applied to a theorem A \mid - ~t, the inference rule NOT_ELIM returns the theorem A \mid - t ==> F.

A |- ~t ----- NOT_ELIM A |- t ==> F

Failure

Fails unless the theorem has a negated conclusion.

IMP_ELIM, NOT_INTRO.

NOT_EQ_SYM

NOT_EQ_SYM : (thm -> thm)

Synopsis

Swaps left-hand and right-hand sides of a negated equation.

Description

When applied to a theorem A |- (t1 = t2), the inference rule NOT_EQ_SYM returns the theorem A |- (t2 = t1).

A |- ~(t1 = t2) ----- NOT_EQ_SYM A |- ~(t2 = t1)

Failure

Fails unless the theorem's conclusion is a negated equation.

See also

DEPTH_CONV, REFL, SYM.

NOT_EXISTS_CONV

NOT_EXISTS_CONV : conv

Synopsis

Moves negation inwards through an existential quantification.

Description

When applied to a term of the form ~(?x.P), the conversion NOT_EXISTS_CONV returns the theorem:

|-~~(?x.P) = !x.~P

Failure

Fails if applied to a term not of the form ~(?x.P).

EXISTS_NOT_CONV, FORALL_NOT_CONV, NOT_FORALL_CONV.

NOT_FORALL_CONV

NOT_FORALL_CONV : conv

Synopsis

Moves negation inwards through a universal quantification.

Description

When applied to a term of the form ~(!x.P), the conversion NOT_FORALL_CONV returns the theorem:

 $|-~(!x.P) = ?x.^{P}$

It is irrelevant whether x occurs free in P.

Failure

Fails if applied to a term not of the form ~(!x.P).

See also

EXISTS_NOT_CONV, FORALL_NOT_CONV, NOT_EXISTS_CONV.

NOT_INTRO

NOT_INTRO : (thm -> thm)

Synopsis

Transforms |- t ==> F into |- ~t.

Description

When applied to a theorem A \mid - t ==> F, the inference rule NOT_INTRO returns the theorem A \mid - ~t.

A |- t ==> F ----- NOT_INTRO A |- ~t

Failure

Fails unless the theorem has an implicative conclusion with F as the consequent.

IMP_ELIM, NOT_ELIM.

NO_CONV

NO_CONV : conv

Synopsis

Conversion that always fails.

Failure

NO_CONV always fails.

See also ALL_CONV.

NO_TAC

NO_TAC : tactic

Synopsis

Tactic which always fails.

Description

Whatever goal it is applied to, NO_TAC always fails with string 'NO_TAC'.

Failure

Always fails.

See also

ALL_TAC, ALL_THEN, FAIL_TAC, NO_THEN.

NO_THEN

NO_THEN : thm_tactical

Theorem-tactical which always fails.

Description

When applied to a theorem-tactic and a theorem, the theorem-tactical NO_THEN always fails with string 'NO_THEN'.

Failure

Always fails when applied to a theorem-tactic and a theorem (note that it never gets as far as being applied to a goal!)

Uses

Writing compound tactics or tacticals.

See also

ALL_TAC, ALL_THEN, FAIL_TAC, NO_TAC.

ONCE_ASM_REWRITE_RULE

ONCE_ASM_REWRITE_RULE : (thm list -> thm -> thm)

Synopsis

Rewrites a theorem once including built-in rewrites and the theorem's assumptions.

Description

ONCE_ASM_REWRITE_RULE applies all possible rewrites in one step over the subterms in the conclusion of the theorem, but stops after rewriting at most once at each subterm. This strategy is specified as for ONCE_DEPTH_CONV. For more details see ASM_REWRITE_RULE, which does search recursively (to any depth) for matching subterms. The general strategy for rewriting theorems is described under GEN_REWRITE_RULE.

Failure

Never fails.

Uses

This tactic is used when rewriting with the hypotheses of a theorem (as well as a given list of theorems and basic_rewrites), when more than one pass is not required or would result in divergence.

304

ASM_REWRITE_RULE, FILTER_ASM_REWRITE_RULE, FILTER_ONCE_ASM_REWRITE_RULE, GEN_REWRITE_RULE, ONCE_DEPTH_CONV, ONCE_REWRITE_RULE, PURE_ASM_REWRITE_RULE, PURE_ONCE_ASM_REWRITE_RULE, PURE_REWRITE_RULE, REWRITE_RULE.

ONCE_ASM_REWRITE_TAC

ONCE_ASM_REWRITE_TAC : (thm list -> tactic)

Synopsis

Rewrites a goal once including built-in rewrites and the goal's assumptions.

Description

ONCE_ASM_REWRITE_TAC behaves in the same way as ASM_REWRITE_TAC, but makes one pass only through the term of the goal. The order in which the given theorems are applied is an implementation matter and the user should not depend on any ordering. See GEN_REWRITE_TAC for more information on rewriting a goal in HOL.

Failure

ONCE_ASM_REWRITE_TAC does not fail and, unlike ASM_REWRITE_TAC, does not diverge. The resulting tactic may not be valid, if the rewrites performed add new assumptions to the theorem eventually proved.

Example

The use of ONCE_ASM_REWRITE_TAC to control the amount of rewriting performed is illustrated below:

```
#ONCE_ASM_REWRITE_TAC []
# (["(a:*) = b"; "(b:*) = c"], "P (a:*): bool") ;;
([(["a = b"; "b = c"], "P b")], -) : subgoals
#(ONCE_ASM_REWRITE_TAC [] THEN ONCE_ASM_REWRITE_TAC [])
# (["(a:*) = b"; "(b:*) = c"], "P (a:*): bool") ;;
([(["a = b"; "b = c"], "P c")], -) : subgoals
```

Uses

ONCE_ASM_REWRITE_TAC can be applied once or iterated as required to give the effect of ASM_REWRITE_TAC, either to avoid divergence or to save inference steps.

basic_rewrites, ASM_REWRITE_TAC, FILTER_ASM_REWRITE_TAC, FILTER_ONCE_ASM_REWRITE_TAC, GEN_REWRITE_TAC, ONCE_ASM_REWRITE_TAC, ONCE_REWRITE_TAC, PURE_ASM_REWRITE_TAC, PURE_ONCE_ASM_REWRITE_TAC, PURE_ONCE_REWRITE_TAC, PURE_REWRITE_TAC, REWRITE_TAC, SUBST_TAC.

ONCE_DEPTH_CONV

ONCE_DEPTH_CONV : (conv -> conv)

Synopsis

Applies a conversion once to the first suitable sub-term(s) encountered in top-down order.

Description

ONCE_DEPTH_CONV c tm applies the conversion c once to the first subterm or subterms encountered in a top-down 'parallel' search of the term tm for which c succeeds. If the conversion c fails on all subterms of tm, the theorem returned is |-tm = tm.

Failure

Never fails.

Example

The following example shows how ONCE_DEPTH_CONV applies a conversion to only the first suitable subterm(s) found in a top-down search:

```
#ONCE_DEPTH_CONV BETA_CONV "(\x. (\y. y + x) 1) 2";;
|- (\x. (\y. y + x)1)2 = (\y. y + 2)1
```

Here, there are two beta-redexes in the input term. One of these occurs within the other, so BETA_CONV is applied only to the outermost one.

Note that the supplied conversion is applied by ONCE_DEPTH_CONV to all independent subterms at which it succeeds. That is, the conversion is applied to every suitable subterm not contained in some other subterm for which the conversions also succeeds, as illustrated by the following example:

#ONCE_DEPTH_CONV num_CONV "(\x. (\y. y + x) 1) 2";; |- (\x. (\y. y + x)1)2 = (\x. (\y. y + x)(SUC 0))(SUC 1)

Here num_CONV is applied to both 1 and 2, since neither term occurs within a larger subterm for which the conversion num_CONV succeeds.

Uses

ONCE_DEPTH_CONV is frequently used when there is only one subterm to which the desired conversion applies. This can be much faster than using other functions that attempt to apply a conversion to all subterms of a term (e.g. DEPTH_CONV). If, for example, the current goal in a goal-directed proof contains only one beta-redex, and one wishes to apply BETA_CONV to it, then the tactic

```
CONV_TAC (ONCE_DEPTH_CONV BETA_CONV)
```

may, depending on where the beta-redex occurs, be much faster than

```
CONV_TAC (TOP_DEPTH_CONV BETA_CONV)
```

ONCE_DEPTH_CONV c may also be used when the supplied conversion c never fails, in which case using a conversion such as DEPTH_CONV c, which applies c repeatedly would never terminate.

Comments

The implementation of this function uses failure to avoid rebuilding unchanged subterms. That is to say, during execution the failure string 'QCONV' may be generated and later trapped. The behaviour of the function is dependent on this use of failure. So, if the conversion given as argument happens to generate a failure with string 'QCONV', the operation of ONCE_DEPTH_CONV will be unpredictable.

See also

DEPTH_CONV, REDEPTH_CONV, TOP_DEPTH_CONV.

ONCE_REWRITE_CONV

ONCE_REWRITE_CONV : (thm list -> conv)

Synopsis

Rewrites a term, including built-in tautologies in the list of rewrites.

Description

ONCE_REWRITE_CONV searches for matching subterms and applies rewrites once at each subterm, in the manner specified for ONCE_DEPTH_CONV. The rewrites which are used are obtained from the given list of theorems and the set of tautologies stored in basic_rewrites. See GEN_REWRITE_CONV for the general method of using theorems to rewrite a term.

Failure

ONCE_REWRITE_CONV does not fail; it does not diverge.

Uses

ONCE_REWRITE_CONV can be used to rewrite a term when recursive rewriting is not desired.

See also

GEN_REWRITE_CONV, PURE_ONCE_REWRITE_CONV, PURE_REWRITE_CONV, REWRITE_CONV.

ONCE_REWRITE_RULE

ONCE_REWRITE_RULE : (thm list -> thm -> thm)

Synopsis

Rewrites a theorem, including built-in tautologies in the list of rewrites.

Description

ONCE_REWRITE_RULE searches for matching subterms and applies rewrites once at each subterm, in the manner specified for ONCE_DEPTH_CONV. The rewrites which are used are obtained from the given list of theorems and the set of tautologies stored in basic_rewrites. See GEN_REWRITE_RULE for the general method of using theorems to rewrite an object theorem.

Failure

ONCE_REWRITE_RULE does not fail; it does not diverge.

Uses

ONCE_REWRITE_RULE can be used to rewrite a theorem when recursive rewriting is not desired.

See also

ASM_REWRITE_RULE, GEN_REWRITE_RULE, ONCE_ASM_REWRITE_RULE, PURE_ONCE_REWRITE_RULE, PURE_REWRITE_RULE, REWRITE_RULE.

ONCE_REWRITE_TAC

ONCE_REWRITE_TAC : (thm list -> tactic)

308

Rewrites a goal only once with basic_rewrites and the supplied list of theorems.

Description

A set of equational rewrites is generated from the theorems supplied by the user and the set of basic tautologies, and these are used to rewrite the goal at all subterms at which a match is found in one pass over the term part of the goal. The result is returned without recursively applying the rewrite theorems to it. The order in which the given theorems are applied is an implementation matter and the user should not depend on any ordering. More details about rewriting can be found under GEN_REWRITE_TAC.

Failure

ONCE_REWRITE_TAC does not fail and does not diverge. It results in an invalid tactic if any of the applied rewrites introduces new assumptions to the theorem eventually proved.

Example

Given a theorem list:

th1 = [|-a = b; |-b = c; |-c = a]

the tactic ONCE_REWRITE_TAC thl can be iterated as required without diverging:

#ONCE_REWRITE_TAC thl ([], "P a");; ([([], "P b")], -) : subgoals #(ONCE_REWRITE_TAC thl THEN ONCE_REWRITE_TAC thl) ([], "P a");; ([([], "P c")], -) : subgoals #(ONCE_REWRITE_TAC thl THEN ONCE_REWRITE_TAC thl THEN ONCE_REWRITE_TAC thl) #([], "P a");; ([([], "P a")], -) : subgoals

Uses

ONCE_REWRITE_TAC can be used iteratively to rewrite when recursive rewriting would diverge. It can also be used to save inference steps.

See also

ASM_REWRITE_TAC, ONCE_ASM_REWRITE_TAC, PURE_ASM_REWRITE_TAC, PURE_ONCE_REWRITE_TAC, PURE_REWRITE_TAC, REWRITE_TAC, SUBST_TAC.

ORELSE

\$ORELSE : (tactic -> tactic -> tactic)

Applies first tactic, and iff it fails, applies the second instead.

Description

If T1 and T2 are tactics, T1 ORELSE T2 is a tactic which applies T1 to a goal, and iff it fails, applies T2 to the goal instead.

Failure

The application of ORELSE to a pair of tactics never fails. The resulting tactic fails if both T1 and T2 fail when applied to the relevant goal.

See also

EVERY, FIRST, THEN.

ORELSEC

\$ORELSEC : (conv -> conv -> conv)

Synopsis

Applies the first of two conversions that succeeds.

Description

(c1 ORELSEC c2) "t" returns the result of applying the conversion c1 to the term "t" if this succeeds. Otherwise (c1 ORELSEC c2) "t" returns the result of applying the conversion c2 to the term "t".

Failure

(c1 ORELSEC c2) "t" fails both c1 and c2 fail when applied to "t".

See also

FIRST_CONV.

ORELSE_TCL

\$ORELSE_TCL : (thm_tactical -> thm_tactical -> thm_tactical)

310

Applies a theorem-tactical, and if it fails, tries a second.

Description

When applied to two theorem-tacticals, ttl1 and ttl2, a theorem-tactic ttac, and a theorem th, if ttl1 ttac th succeeds, that gives the result. If it fails, the result is ttl2 ttac th, which may itself fail.

Failure

ORELSE_TCL fails if both the theorem-tacticals fail when applied to the given theorem-tactic and theorem.

See also

EVERY_TCL, FIRST_TCL, THEN_TCL.

OR_EXISTS_CONV

OR_EXISTS_CONV : conv

Synopsis

Moves an existential quantification outwards through a disjunction.

Description

When applied to a term of the form $(?x.P) \setminus (?x.Q)$, the conversion OR_EXISTS_CONV returns the theorem:

 $|-(?x.P) \setminus (?x.Q) = (?x. P \setminus Q)$

Failure

Fails if applied to a term not of the form $(?x.P) \setminus (?x.Q)$.

See also

EXISTS_OR_CONV, LEFT_OR_EXISTS_CONV, RIGHT_OR_EXISTS_CONV.

OR_FORALL_CONV

OR_FORALL_CONV : conv

Moves a universal quantification outwards through a disjunction.

Description

When applied to a term of the form $(!x.P) \setminus (!x.Q)$, where x is free in neither P nor Q, OR_FORALL_CONV returns the theorem:

 $|-(!x. P) \setminus (!x. Q) = (!x. P \setminus Q)$

Failure

OR_FORALL_CONV fails if it is applied to a term not of the form $(!x.P) \setminus (!x.Q)$, or if it is applied to a term $(!x.P) \setminus (!x.Q)$ in which the variable x is free in either P or Q.

See also

FORALL_OR_CONV, LEFT_OR_FORALL_CONV, RIGHT_OR_FORALL_CONV.

overload_on

```
Parse.overload_on : string * term -> unit
```

Synopsis

Establishes a constant as one of the overloading possibilities for a string.

Description

Calling overload_on(name,tm) establishes tm as a possible resolution of the overloaded name. The term tm must be a constant. The call to overload_on also ensures that tm is the first in the list of possible resolutions chosen when a string might be parsed into a term in more than one way.

Failure

Fails if the term argument is not a constant.

Example

We define the equivalent of intersection over predicates:

```
- val inter = new_definition("inter", Term'inter p q x = p x /\ q x');
<<HOL message: inventing new type variable names: 'a.>>
> val inter = |- !p q x. inter p q x = p x /\ q x : Thm.thm
```

Then we can set up the overloading we want. One of the possible meanings for the

312

string / is usual logical conjunction:

```
- overload_on ("/\\", Term'$/\');
> val it = () : unit
```

We also overload on our new intersection constant, and can be sure that in ambiguous situations, it will be preferred:

```
- overload_on ("/\\", Term'inter');
<<HOL message: inventing new type variable names: 'a.>>
> val it = () : unit
- Term'p /\ q';
<<HOL message: more than one resolution of overloading was possible.>>
<<HOL message: inventing new type variable names: 'a.>>
> val it = 'p /\ q' : Term.term
- type_of it;
> val it = ':'a -> bool' : Type.hol_type
```

In order to make normal conjunction the preferred choice, we can repeat the call to overload_on:

```
- overload_on ("/\\", Term'$/\ :bool -> bool -> bool');
> val it = () : unit
- Term'p /\ q';
<<HOL message: more than one resolution of overloading was possible.>>
> val it = 'p /\ q' : Term.term
- type_of it;
> val it = ':bool' : Type.hol_type
```

Note that in order to override the overloading, we had to specify the type of the logical conjunction explicitly. Otherwise, the parsing would have taken the $/\$ to mean our previously preferred alternative (inter).

Comments

Overloading with abandon can lead to input that is very hard to make sense of, and so should be used with caution.

See also

clear_overloads_on.

р

p : (int -> void)

Prints the top levels of the subgoal package goal stack.

Description

The function p is part of the subgoal package. It is an abbreviation for the function print_state. For a description of the subgoal package, see set_goal.

Failure

Never fails.

Uses

Examining the proof state during an interactive proof session.

See also

b, backup, backup_limit, e, expand, expandf, g, get_state, print_state, r, rotate, save_top_thm, set_goal, set_state, top_goal, top_thm.

pair

pair : (* -> ** -> (* # **))

Synopsis

Makes two values into a pair.

Description pair x y returns (x,y).

Failure

Never fails.

See also

fst, snd, curry, uncurry.

PAIRED_BETA_CONV

PAIRED_BETA_CONV : conv

314

Performs generalized beta conversion for tupled beta-redexes.

Description

The conversion PAIRED_BETA_CONV implements beta-reduction for certain applications of tupled lambda abstractions called 'tupled beta-redexes'. Tupled lambda abstractions have the form "\<vs>.tm", where <vs> is an arbitrarily-nested tuple of variables called a 'varstruct'. For the purposes of PAIRED_BETA_CONV, the syntax of varstructs is given by:

<vs> ::= (v1,v2) | (<vs>,v) | (v,<vs>) | (<vs>,<vs>)

where v, v1, and v2 range over variables. A tupled beta-redex is an application of the form "(\<vs>.tm) t", where the term "t" is a nested tuple of values having the same structure as the varstruct <vs>. For example, the term:

"(\((a,b),(c,d)). a + b + c + d) ((1,2),(3,4))"

is a tupled beta-redex, but the term:

"(\((a,b),(c,d)). a + b + c + d) ((1,2),p)"

is not, since p is not a pair of terms.

Given a tupled beta-redex "(\<vs>.tm) t", the conversion PAIRED_BETA_CONV performs generalized beta-reduction and returns the theorem

|- (\<vs>.tm) t = t[t1,...,tn/v1,...,vn]

where ti is the subterm of the tuple t that corresponds to the variable vi in the varstruct <vs>. In the simplest case, the varstruct <vs> is flat, as in the term:

"(\(v1,...,vn).t) (t1,...,tn)"

When applied to a term of this form, PAIRED_BETA_CONV returns:

|-((v1, ..., vn).t) (t1, ..., tn) = t[t1, ..., tn/v1, ..., vn]

As with ordinary beta-conversion, bound variables may be renamed to prevent free variable capture. That is, the term t[t1,...,tn/v1,...,vn] in this theorem is the result of substituting ti for vi in parallel in t, with suitable renaming of variables to prevent free variables in t1, ..., tn becoming bound in the result.

Failure

PAIRED_BETA_CONV tm fails if tm is not a tupled beta-redex, as described above. Note that ordinary beta-redexes are specifically excluded: PAIRED_BETA_CONV fails when applied to "(\v.t)u". For these beta-redexes, use BETA_CONV.

Example

The following is a typical use of the conversion:

#PAIRED_BETA_CONV "(\((a,b),(c,d)). a + b + c + d) ((1,2),(3,4))";; |- (\((a,b),c,d). a + (b + (c + d)))((1,2),3,4) = 1 + (2 + (3 + 4))

Note that the term to which the tupled lambda abstraction is applied must have the same structure as the varstruct. For example, the following succeeds:

#PAIRED_BETA_CONV "(\((a,b),p). a + b) ((1,2),(3+5,4))";; |- (\((a,b),p). a + b)((1,2),3 + 5,4) = 1 + 2

but the following call to PAIRED_BETA_CONV fails:

#PAIRED_BETA_CONV "(\((a,b),(c,d)). a + b + c + d) ((1,2),p)";;
evaluation failed PAIRED_BETA_CONV

because p is not a pair.

See also

BETA_CONV, BETA_RULE, BETA_TAC, LIST_BETA_CONV, RIGHT_BETA, RIGHT_LIST_BETA.

PAIRED_ETA_CONV

PAIRED_ETA_CONV : conv

Synopsis

Performs generalized eta conversion for tupled eta-redexes.

Description

The conversion PAIRED_ETA_CONV generalizes ETA_CONV to eta-redexes with tupled abstractions.

PAIRED_ETA_CONV "\(v1..(..)..vn). f (v1..(..)..vn)" = |- \(v1..(..)..vn). f (v1..(..)..vn) = f

Failure

Fails unless the given term is a paired eta-redex as illustrated above.

Comments

Note that this result cannot be achieved by ordinary eta-reduction because the tupled abstraction is a surface syntax for a term which does not correspond to a normal pattern

for eta reduction. Disabling the relevant prettyprinting reveals the true form of a paired eta redex:

```
#set_flag('print_uncurry',false);;
true : bool
#let tm = "\(x:num,y:num). FST (x,y)";;
tm = "UNCURRY(\x y. FST(x,y))" : term
```

Example

The following is a typical use of the conversion:

```
let SELECT_PAIR_EQ = PROVE
("(@(x:*,y:**). (a,b) = (x,y)) = (a,b)",
CONV_TAC (ONCE_DEPTH_CONV PAIRED_ETA_CONV) THEN
ACCEPT_TAC (SYM (MATCH_MP SELECT_AX (REFL "(a:*,b:**)"))));;
```

See also

ETA_CONV.

parents

parents : (string -> string list)

Synopsis

Lists the parent theories of a named theory.

Description

The function parents returns a list of strings that identify the parent theories of a named theory. The function does not recursively descend the theory hierarchy in search of the 'leaf' theories. The named theory must be the current theory or an ancestor of the current theory.

Failure

Fails if the named theory is not an ancestor of the current theory.

Example

Initially, the only parent is the main HOL theory:

```
#new_theory 'my-theory';;
() : void
#parents 'my-theory';;
['HOL'] : string list
#parents 'HOL';;
['tydefs'; 'sum'; 'one'; 'BASIC-HOL'] : string list
#parents 'tydefs';;
['ltree'; 'BASIC-HOL'] : string list
#parents 'string';;
evaluation failed parents -- string is not an ancestor
```

However, loading the string library creates several additional ancestor theories:

```
#load_library 'string';;
Loading library 'string' ...
Updating search path
.Updating help search path
.Declaring theory string a new parent
Theory string loaded
.....
Library 'string' loaded.
() : void
#parents 'string';;
['ascii'; 'HOL'] : string list
#parents 'my-theory';;
['string'; 'HOL'] : string list
```

See also

ancestors, ancestry.

318

parse_from_grammars

```
Parse.parse_from_grammars :
    (parse_type.grammar * term_grammar.grammar) ->
    ((hol_type frag list -> hol_type) * (term frag list -> term))
```

Synopsis

Returns parsing functions based on the supplied grammars.

Description

When given a pair consisting of a type and a term grammar, this function returns parsing functions that use those grammars to turn strings (strictly, quotations) into types and terms respectively.

Failure

Can't fail immediately. However, when the precedence matrix for the term parser is built on first application of the term parser, this may generate precedence conflict errors depending on the rules in the grammar.

Example

First the user loads arithmeticTheory to augment the built-in grammar with the ability to lex numerals and deal with symbols such as + and -:

```
- load "arithmeticTheory";
> val it = () : unit
- val t = Term'2 + 3';
> val t = '2 + 3' : Term.term
```

Then the parse_from_grammars function is used to make the values Type and Term use the grammar present in the simpler theory of booleans. Using this function fails to parse numerals or even the + infix:

```
- val (Type,Term) = parse_from_grammars boolTheory.bool_grammars;
> val Type = fn : Type.hol_type frag list -> Type.hol_type
  val Term = fn : Term.term frag list -> Term.term
- Term'2 + 3';
<<HOL message: No numerals currently allowed.>>
! Uncaught exception:
! HOL_ERR <poly>
- Term'x + y';
<<HOL message: inventing new type variable names: 'a, 'b.>>
> val it = 'x $+ y' : Term.term
```

But, as the last example above also demonstrates, the pretty-printer is still dependent

on the global grammar, and the global value of Term can still be accessed through the Parse structure:

- t;
> val it = '2 + 3' : Term.term
- Parse.Term'2 + 3';
> val it = '2 + 3' : Term.term

Uses

This function is used to ensure that library code has access to a term parser that is a known quantity. In particular, it is not good form to have library code that depends on the default parsers Term and Type. When the library is loaded, which may happen at any stage, these global values may be such that the parsing causes quite unexpected results or failures.

See also

add_rule, Term, Type

parse_in_context

Parse.parse_in_context : term list -> term quotation -> term

Synopsis

Parses a quotation into a term, using the terms as typing context.

Description

Where the Term function parses a quotation in isolation of all possible contexts (except inasmuch as the global grammar provides a form of context), this function uses the additional parameter, a list of terms, to help in giving variables in the quotation types.

Thus, Term'x' will either guess the type '':'a'' for this quotation, or refuse to parse it at all, depending on the value of the guessing_tyvars flag. The parse_in_context function, in contrast, will attempt to find a type for x from the list of free variables.

If the quotation already provides enough context in itself to determine a type for a variable, then the context is not consulted, and a conflicting type there for a given variable is ignored.

Failure

Fails if the quotation doesn't make syntactic sense, or if the assignment of context types to otherwise unconstrained variables in the quotation causes overloading resolution to

fail. The latter would happen if the variable x was given boolean type in the context, if + was overloaded to be over either :num or :int, and if the quotation was x + y.

Example

<< There should be an example here >>

Uses

Used in many of the Q module's variants of the standard tactics in order to have a goal provide contextual information to the parsing of arguments to tactics.

See also

Term

parse_preTerm

Parse.parse_preTerm : term quotation -> Absyn.absyn

Synopsis

Implements the first phase of term parsing; the removal of special syntax.

Description

The "let" expression 'let x = e1 in e2' will turn into

```
APP(APP(IDENT "LET", LAM(VIDENT "x", IDENT "e2")), IDENT "e1")
```

The record syntax 'rec.fld1' is converted into something of the form

APP(IDENT "....fld1", IDENT "rec")

where the dots will actually be equal to the value of GrammarSpecials.recsel_special (a string).

Failure

Fails if the quotation provided includes a syntax error. This phase of parsing is unconcerned with types, and will happily parse meaningless expressions that are syntactically valid. Example

Uses

Comments

PART_MATCH

PART_MATCH : ((term -> term) -> thm -> term -> thm)

Synopsis

Instantiates a theorem by matching part of it to a term.

Description

When applied to a 'selector' function of type term -> term, a theorem and a term:

PART_MATCH fn (A |- !x1...xn. t) tm

the function PART_MATCH applies fn to t' (the result of specializing universally quantified variables in the conclusion of the theorem), and attempts to match the resulting term to the argument term tm. If it succeeds, the appropriately instantiated version of the theorem is returned.

Failure

Fails if the selector function fn fails when applied to the instantiated theorem, or if the match fails with the term it has provided.

Example

Suppose that we have the following theorem:

th = |-!x.x => x

then the following:

PART_MATCH (fst o dest_imp) th "T"

results in the theorem:

|- T ==> T

because the selector function picks the antecedent of the implication (the inbuilt specialization gets rid of the universal quantifier), and matches it to T.

See also

INST_TYPE, INST_TY_TERM, match.

PAT_ASSUM

```
Ho_tactics.PAT_ASSUM : term -> thm_tactic -> tactic
```

Synopsis

Finds the first assumption that matches the term argument, applies the theorem tactic to it, and removes this assumption.

Description

The tactic

PAT_ASSUM tm ttac ([A1; ...; An], g)

finds the first Ai which matches tm using higher-order matching in the sense of Ho_match.match_ter Unless there is just one match otherwise, free variables in the pattern that are also free in the assumptions or the goal must not be bound by the match. In effect, these variables are being treated as local constants.

Failure

Fails if the term doesn't match any of the assumptions, or if the theorem-tactic fails when applied to the first assumption that does match the term.

Example

The tactic

```
PAT_ASSUM ''x:num = y'' SUBST_ALL_TAC
```

searches the assumptions for an equality over numbers and causes its right hand side to be substituted for its left hand side throughout the goal and assumptions. It also removes the equality from the assumption list. Trying to use FIRST_ASSUM above (i.e., replacing PAT_ASSUM with FIRST_ASSUM and dropping the term argument entirely) would require that the desired equality was the first such on the list of assumptions, and would leave an equality on the assumption list of the form x = x. If one is trying to solve the goal

{ !x. f x = g (x + 1), !x. g x = f0 (f x)} ?- f x = g y

rewriting with the assumptions directly will cause a loop. Instead, one might want to rewrite with the formula for f. This can be done in an assumption-order-indepedent way with

PAT_ASSUM (Term'!x. f x = f' x') (fn th => REWRITE_TAC [th])

This use of the tactic exploits higher order matching to match the RHS of the assumption, and the fact that f is effectively a local constant in the goal to find the correct assumption.

See also

ASSUM_LIST, EVERY, PAT_ASSUM, EVERY_ASSUM, FIRST, MAP_EVERY, MAP_FIRST, UNDISCH_THEN, match_term.

POP_ASSUM

POP_ASSUM : (thm_tactic -> tactic)

Synopsis

Applies tactic generated from the first element of a goal's assumption list.

Description

When applied to a theorem-tactic and a goal, POP_ASSUM applies the theorem-tactic to the ASSUMED first element of the assumption list, and applies the resulting tactic to the goal without the first assumption in its assumption list:

POP_ASSUM f ({A1;...;An} ?- t) = f (A1 |- A1) ({A2;...;An} ?- t)

Failure

Fails if the assumption list of the goal is empty, or the theorem-tactic fails when applied to the popped assumption, or if the resulting tactic fails when applied to the goal (with depleted assumption list).

Comments

It is possible simply to use the theorem ASSUME A1 as required rather than use POP_ASSUM; this will also maintain A1 in the assumption list, which is generally useful. In addition, this approach can equally well be applied to assumptions other than the first.

There are admittedly times when POP_ASSUM is convenient, but it is most unwise to use it if there is more than one assumption in the assumption list, since this introduces a dependency on the ordering, which is vulnerable to changes in the HOL system.

Another point to consider is that if the relevant assumption has been obtained by DISCH_TAC, it is often cleaner to use DISCH_THEN with a theorem-tactic. For example, instead of:

DISCH_TAC THEN POP_ASSUM (\th. SUBST1_TAC (SYM th))

one might use

DISCH_THEN (SUBST1_TAC o SYM)

Example

The goal:

 $\{4 = SUC x\}$?- x = 3

can be solved by:

```
POP_ASSUM (\th. REWRITE_TAC[REWRITE_RULE[num_CONV "4"; INV_SUC_EQ] th]))
```

Uses

Making more delicate use of an assumption than rewriting or resolution using it.

See also

ASSUM_LIST, EVERY_ASSUM, IMP_RES_TAC, POP_ASSUM_LIST, REWRITE_TAC.

POP_ASSUM_LIST

POP_ASSUM_LIST : ((thm list -> tactic) -> tactic)

Synopsis

Generates a tactic from the assumptions, discards the assumptions and applies the tactic.

Description

When applied to a function and a goal, POP_ASSUM_LIST applies the function to a list of theorems corresponding to the ASSUMEd assumptions of the goal, then applies the resulting tactic to the goal with an empty assumption list.

POP_ASSUM_LIST f ({A1;...;An} ?- t) = f [A1 |- A1; ...; An |- An] (?- t)

Failure

Fails if the function fails when applied to the list of ASSUMEd assumptions, or if the resulting tactic fails when applied to the goal with no assumptions.

Comments

There is nothing magical about POP_ASSUM_LIST: the same effect can be achieved by using ASSUME a explicitly wherever the assumption a is used. If POP_ASSUM_LIST is used, it is unwise to select elements by number from the ASSUMEd-assumption list, since this introduces a dependency on ordering.

Example

Suppose we have a goal of the following form:

{a /\ b, c, (d /\ e) /\ f} ?- t

Then we can split the conjunctions in the assumption list apart by applying the tactic:

POP_ASSUM_LIST (MAP_EVERY STRIP_ASSUME_TAC)

which results in the new goal:

{a, b, c, d, e, f} ?- t

Uses

Making more delicate use of the assumption list than simply rewriting or using resolution.

See also

ASSUM_LIST, EVERY_ASSUM, IMP_RES_TAC, POP_ASSUM, REWRITE_TAC.

prefer_form_with_tok

Parse.prefer_form_with_tok : {term_name : string, tok : string} -> unit

326

Synopsis

Sets a grammar rule's preferred flag, causing it to be preferentially printed.

Description

A call to prefer_form_with_tok causes the parsing/pretty-printing rule specified by the term_name-tok combination to be the preferred rule for pretty-printing purposes. This change affects the global grammar.

Failure

Never fails.

Example

The initially preferred rule for conditional expressions causes them to print using the if-then-else syntax. If the user prefers the "traditional" syntax with =>-|, this change can be brought about as follows:

```
- prefer_form_with_tok {term_name = "COND", tok = "=>"};
> val it = () : unit
- Term'if p then q else r';
<<HOL message: inventing new type variable names: 'a.>>
> val it = 'p => q | r' : Term.term
```

Comments

As the example above demonstrates, using this function does not affect the parser at all.

There is a companion temp_prefer_form_with_tok function, which has the same effect on the global grammar, but which does not cause this effect to persist when the current theory is exported.

See also

clear_prefs_for_term

print_term

Parse.print_term : term -> unit

Synopsis

Prints a term to the screen (standard out).

Description

The function print_term prints a term to the screen. It first converts the term into a string, and then outputs that string to the standard output stream.

The conversion to the string is done by term_to_string. The term is printed using the pretty-printing information contained in the global grammar.

Failure

Should never fail.

See also

term_to_string

prove

```
prove : ((term # tactic) -> thm)
```

Synopsis

Attempts to prove a boolean term using the supplied tactic.

Description

When applied to a term-tactic pair (tm,tac), the function prove attempts to prove the goal ?- tm, that is, the term tm with no assumptions, using the tactic tac. If prove succeeds, it returns the corresponding theorem A |- tm, where the assumption list A may not be empty if the tactic is invalid; prove has no inbuilt validity-checking.

Failure

Fails if the term is not of type bool (and so cannot possibly be the conclusion of a theorem), or if the tactic cannot solve the goal.

Comments

The function PROVE provides almost identical functionality, and will also list unsolved goals if the tactic fails. It is therefore preferable for most purposes.

See also

PROVE, prove_thm, TAC_PROOF, VALID.

PROVE

Compat.PROVE : (term * tactic) -> thm

Synopsis

Attempts to prove a boolean term using the supplied tactic.

Description

Found in the hol88 library. When applied to a term-tactic pair (tm,tac), the function PROVE attempts to prove the goal ?- tm, that is, the term tm with no assumptions, using the tactic tac. If PROVE succeeds, it returns the corresponding theorem A |- tm, where the assumption list A may not be empty if the tactic is invalid; PROVE has no inbuilt validity-checking.

Failure

Fails if the term is not of type bool (and so cannot possibly be the conclusion of a theorem), or if the tactic cannot solve the goal. Also fails if the hol88 library has not been loaded.

Comments

In hol90, use prove instead; in hol90 PROVE has been replaced by prove and prove_thm has been replaced by store_thm.

See also

TAC_PROOF, prove, prove_thm, VALID.

prove_abs_fn_one_one

prove_abs_fn_one_one : (thm -> thm)

Synopsis

Proves that a type abstraction function is one-to-one (injective).

Description

If th is a theorem of the form returned by the function define_new_type_bijections:

|- (!a. abs(rep a) = a) /\ (!r. P r = (rep(abs r) = r))

then prove_abs_fn_one_one th proves from this theorem that the function abs is one-toone for values that satisfy P, returning the theorem:

|- !r r'. P r ==> P r' ==> ((abs r = abs r') = (r = r'))

Failure

Fails if applied to a theorem not of the form shown above.

See also

new_type_definition, define_new_type_bijections, prove_abs_fn_onto, prove_rep_fn_one_one, prove_rep_fn_onto.

prove_abs_fn_onto

prove_abs_fn_onto : (thm -> thm)

Synopsis

Proves that a type abstraction function is onto (surjective).

Description

If th is a theorem of the form returned by the function define_new_type_bijections:

|-(!a. abs(rep a) = a) / (!r. P r = (rep(abs r) = r))

then prove_abs_fn_onto th proves from this theorem that the function abs is onto, returning the theorem:

|- !a. ?r. (a = abs r) /\ P r

Failure

Fails if applied to a theorem not of the form shown above.

See also

```
new_type_definition, define_new_type_bijections, prove_abs_fn_one_one,
prove_rep_fn_one_one, prove_rep_fn_onto.
```

prove_cases_thm

prove_cases_thm : (thm -> thm)

Synopsis

Proves a structural cases theorem for an automatically-defined concrete type.

Description

prove_cases_thm takes as its argument a structural induction theorem, in the form returned by prove_induction_thm for an automatically-defined concrete type. When applied to such a theorem, prove_cases_thm automatically proves and returns a theorem which states that every value the concrete type in question is denoted by the value returned by some constructor of the type.

Failure

Fails if the argument is not a theorem of the form returned by prove_induction_thm

Example

Given the following structural induction theorem for labelled binary trees:

|- !P. (!x. P(LEAF x)) /\ (!b1 b2. P b1 /\ P b2 ==> P(NODE b1 b2)) ==>
 (!b. P b)

prove_cases_thm proves and returns the theorem:

|- !b. (?x. b = LEAF x) \setminus (?b1 b2. b = NODE b1 b2)

This states that every labelled binary tree b is either a leaf node with a label x or a tree with two subtrees b1 and b2.

See also

```
define_type, INDUCT_THEN, new_recursive_definition,
prove_constructors_distinct, prove_constructors_one_one, prove_induction_thm,
prove_rec_fn_exists.
```

prove_constructors_distinct

```
prove_constructors_distinct : (thm -> thm)
```

Synopsis

Proves that the constructors of an automatically-defined concrete type yield distinct values.

Description

prove_constructors_distinct takes as its argument a primitive recursion theorem, in the form returned by define_type for an automatically-defined concrete type. When applied to such a theorem, prove_constructors_distinct automatically proves and returns a theorem which states that distinct constructors of the concrete type in question yield distinct values of this type.

Failure

Fails if the argument is not a theorem of the form returned by define_type, or if the concrete type in question has only one constructor.

Example

Given the following primitive recursion theorem for labelled binary trees:

|- !f0 f1. ?! fn. (!x. fn(LEAF x) = f0 x) /\ (!b1 b2. fn(NODE b1 b2) = f1(fn b1)(fn b2)b1 b2)

prove_constructors_distinct proves and returns the theorem:

|-!x b1 b2. ~(LEAF x = NODE b1 b2)

This states that leaf nodes are different from internal nodes. When the concrete type in question has more than two constructors, the resulting theorem is just conjunction of inequalities of this kind.

See also

```
define_type, INDUCT_THEN, new_recursive_definition, prove_cases_thm,
prove_constructors_one_one, prove_induction_thm, prove_rec_fn_exists.
```

prove_constructors_one_one

prove_constructors_one_one : (thm -> thm)

Synopsis

Proves that the constructors of an automatically-defined concrete type are injective.

Description

prove_constructors_one_one takes as its argument a primitive recursion theorem, in the form returned by define_type for an automatically-defined concrete type. When applied to such a theorem, prove_constructors_one_one automatically proves and returns a theorem which states that the constructors of the concrete type in question are injective (one-to-one). The resulting theorem covers only those constructors that take arguments (i.e. that are not just constant values).

Failure

Fails if the argument is not a theorem of the form returned by define_type, or if all the constructors of the concrete type in question are simply constants of that type.

Example

Given the following primitive recursion theorem for labelled binary trees:

|- !f0 f1. ?! fn. (!x. fn(LEAF x) = f0 x) /\ (!b1 b2. fn(NODE b1 b2) = f1(fn b1)(fn b2)b1 b2)

prove_constructors_one_one proves and returns the theorem:

|- (!x x'. (LEAF x = LEAF x') = (x = x')) /\
 (!b1 b2 b1' b2'.
 (NODE b1 b2 = NODE b1' b2') = (b1 = b1') /\ (b2 = b2'))

This states that the constructors LEAF and NODE are both injective.

See also

```
define_type, INDUCT_THEN, new_recursive_definition, prove_cases_thm,
prove_constructors_distinct, prove_induction_thm, prove_rec_fn_exists.
```

PROVE_HYP

PROVE_HYP : (thm -> thm -> thm)

Synopsis

Eliminates a provable assumption from a theorem.

Description

When applied to two theorems, PROVE_HYP returns a theorem having the conclusion of the second. The new hypotheses are the union of the two hypothesis sets (first deleting,

however, the conclusion of the first theorem from the hypotheses of the second).

A1 |- t1 A2 |- t2 ----- PROVE_HYP A1 u (A2 - {t1}) |- t2

Failure

Never fails.

Comments

This is the Cut rule. It is not necessary for the conclusion of the first theorem to be the same as an assumption of the second, but PROVE_HYP is otherwise of doubtful value.

See also

DISCH, MP, UNDISCH.

prove_induction_thm

```
prove_induction_thm : (thm -> thm)
```

Synopsis

Derives structural induction for an automatically-defined concrete type.

Description

prove_induction_thm takes as its argument a primitive recursion theorem, in the form returned by define_type for an automatically-defined concrete type. When applied to such a theorem, prove_induction_thm automatically proves and returns a theorem that states a structural induction principle for the concrete type described by the argument theorem. The theorem returned by prove_induction_thm is in a form suitable for use with the general structural induction tactic INDUCT_THEN.

Failure

Fails if the argument is not a theorem of the form returned by define_type.

Example

Given the following primitive recursion theorem for labelled binary trees:

```
|- !f0 f1.
    ?! fn.
    (!x. fn(LEAF x) = f0 x) /\
    (!b1 b2. fn(NODE b1 b2) = f1(fn b1)(fn b2)b1 b2)
```

prove_induction_thm proves and returns the theorem:

```
|- !P. (!x. P(LEAF x)) /\ (!b1 b2. P b1 /\ P b2 ==> P(NODE b1 b2)) ==>
    (!b. P b)
```

This theorem states the principle of structural induction on labelled binary trees: if a predicate P is true of all leaf nodes, and if whenever it is true of two subtrees b1 and b2 it is also true of the tree NODE b1 b2, then P is true of all labelled binary trees.

See also

```
define_type, INDUCT_THEN, new_recursive_definition, prove_cases_thm,
prove_constructors_distinct, prove_constructors_one_one, prove_rec_fn_exists.
```

prove_rec_fn_exists

prove_rec_fn_exists : (thm -> term -> thm)

Synopsis

Proves the existence of a primitive recursive function over a concrete recursive type.

Description

prove_rec_fn_exists is a version of new_recursive_definition which proves only that the required function exists; it does not make a constant specification. The first argument is a theorem of the form returned by define_type, and the second is a usersupplied primitive recursive function definition. The theorem which is returned asserts the existence of the recursively-defined function in question (if it is primitive recursive over the type characterized by the theorem given as the first argument). See the entry for new_recursive_definition for details.

Failure

As for new_recursive_definition.

Example

Given the following primitive recursion theorem for labelled binary trees:

```
|- !f0 f1.
   ?! fn.
   (!x. fn(LEAF x) = f0 x) /\
   (!b1 b2. fn(NODE b1 b2) = f1(fn b1)(fn b2)b1 b2)
```

prove_rec_fn_exists can be used to prove the existence of primitive recursive functions over binary trees. Suppose the value of th is this theorem. Then the existence of a recursive function Leaves, which computes the number of leaves in a binary tree, can be proved as shown below:

The result should be compared with the example given under new_recursive_definition.

See also

define_type, new_recursive_definition.

prove_rep_fn_one_one

prove_rep_fn_one_one : (thm -> thm)

Synopsis

Proves that a type representation function is one-to-one (injective).

Description

If th is a theorem of the form returned by the function define_new_type_bijections:

|- (!a. abs(rep a) = a) /\ (!r. P r = (rep(abs r) = r))

then prove_rep_fn_one_one th proves from this theorem that the function rep is one-toone, returning the theorem:

|- !a a'. (rep a = rep a') = (a = a')

Failure

Fails if applied to a theorem not of the form shown above.

See also

new_type_definition, define_new_type_bijections, prove_abs_fn_one_one, prove_abs_fn_onto, prove_rep_fn_onto.

prove_rep_fn_onto

prove_rep_fn_onto : (thm -> thm)

Synopsis

Proves that a type representation function is onto (surjective).

Description

If th is a theorem of the form returned by the function define_new_type_bijections:

|- (!a. abs(rep a) = a) /\ (!r. P r = (rep(abs r) = r))

then prove_rep_fn_onto th proves from this theorem that the function rep is onto the set of values that satisfy P, returning the theorem:

|- !r. P r = (?a. r = rep a)

Failure

Fails if applied to a theorem not of the form shown above.

See also

```
new_type_definition, define_new_type_bijections, prove_abs_fn_one_one,
prove_abs_fn_onto, prove_rep_fn_one_one.
```

prove_thm

Compat.prove_thm : (string * term * tactic) -> thm

Synopsis

Attempts to prove a boolean term using the supplied tactic, then save the theorem.

Description

Found in the hol88 library. When applied to a triple (s,tm,tac), giving the name to save the theorem under, the term to prove (with no assumptions) and the tactic to perform

the proof, the function prove_thm attempts to prove the goal ?- tm, that is, the term tm with no assumptions, using the tactic tac. If prove_thm succeeds, it attempts to save the resulting theorem in the current theory segment, and if this succeeds, the saved theorem is returned.

Failure

Fails if the term is not of type bool (and so cannot possibly be the conclusion of a theorem), or if the tactic cannot solve the goal. In addition, prove_thm will fail if the theorem cannot be saved, e.g. because there is already a theorem of that name in the current theory segment, or if the resulting theorem has assumptions; clearly this can only happen if the tactic was invalid, so this gives some measure of validity checking. The function is not available unless the hol88 library has been loaded.

Comments

In hol90, use store_thm instead; the cognitive dissonance between prove, PROVE, and prove_thm proved to be too much for the author, so in hol90 PROVE doesn't exist: there is only prove; and prove_thm doesn't exist: it has been replaced by store_thm.

See also

prove, PROVE, TAC_PROOF, VALID.

Psyntax

Psyntax : Psyntax_sig

Synopsis

A structure that provides a tuple-style environment for term manipulation.

Description

A lot of the familiar term construction and decomposition functions from hol88 have different types in hol90. For those longing for the good old days, Psyntax provides hol88-style types. The functions provided by Psyntax return exactly the same results as their hol90 counterparts.

Each function in the Psyntax structure has a corresponding function in the Rsyntax structure, and vice versa. One can flip-flop between the two structures by opening one and then the other. One can also use long identifiers in order to use both syntaxes at once.

Failure

Never fails.

Example

The following shows how to open the Psyntax structure and the functions that subsequently become available in the top level environment. Documentation for each of these functions is available online.

```
- open Psyntax;
open Psyntax
 val mk_var = fn : string * hol_type -> term
 val mk_const = fn : string * hol_type -> term
 val mk_comb = fn : term * term -> term
 val mk_abs = fn : term * term -> term
 val mk_primed_var = fn : string * hol_type -> term
  val mk_eq = fn : term * term -> term
  val mk_imp = fn : term * term -> term
 val mk_select = fn : term * term -> term
 val mk_forall = fn : term * term -> term
  val mk_exists = fn : term * term -> term
 val mk_conj = fn : term * term -> term
  val mk_disj = fn : term * term -> term
 val mk_cond = fn : term * term * term -> term
 val mk_pair = fn : term * term -> term
 val mk_let = fn : term * term -> term
 val mk_cons = fn : term * term -> term
  val mk_list = fn : term list * hol_type -> term
  val mk_pabs = fn : term * term -> term
  val dest_var = fn : term -> string * hol_type
 val dest_const = fn : term -> string * hol_type
  val dest_comb = fn : term -> term * term
  val dest_abs = fn : term -> term * term
  val dest_eq = fn : term -> term * term
  val dest_imp = fn : term -> term * term
 val dest_select = fn : term -> term * term
 val dest_forall = fn : term -> term * term
  val dest_exists = fn : term -> term * term
 val dest_conj = fn : term -> term * term
  val dest_disj = fn : term -> term * term
 val dest_cond = fn : term -> term * term * term
  val dest_pair = fn : term -> term * term
  val dest_let = fn : term -> term * term
  val dest_cons = fn : term -> term * term
  val dest_list = fn : term -> term list * term
  val dest_pabs = fn : term -> term * term
  val mk_type = fn : string * hol_type list -> hol_type
 val dest_type = fn : hol_type -> string * hol_type list
  val subst = fn : (term * term) list -> term -> term
  val subst_occs = fn : int list list -> (term * term) list -> term -> term
 val inst = fn : term list -> (hol_type * hol_type) list -> term -> term
  val INST = fn : (term * term) list -> thm -> thm
 val match_type = fn : hol_type -> hol_type -> (hol_type * hol_type) list
  val match_term = fn
    : term -> term -> (term * term) list * (hol_type * hol_type) list
 val SUBST = fn : (thm * term) list -> term -> thm -> thm
  val SUBST_CONV = fn : (thm * term) list -> term -> term -> thm
  val INST_TYPE = fn : (hol_type * hol_type) list -> thm -> thm
  val INST_TY_TERM = fn
    : (term * term) list * (hol_type * hol_type) list -> thm -> thm
  val new_type = fn : int -> string -> unit
```

PURE_ASM_REWRITE_RULE

PURE_ASM_REWRITE_RULE

PURE_ASM_REWRITE_RULE : (thm list -> thm -> thm)

Synopsis

Rewrites a theorem including the theorem's assumptions as rewrites.

Description

The list of theorems supplied by the user and the assumptions of the object theorem are used to generate a set of rewrites, without adding implicitly the basic tautologies stored under basic_rewrites. The rule searches for matching subterms in a top-down recursive fashion, stopping only when no more rewrites apply. For a general description of rewriting strategies see GEN_REWRITE_RULE.

Failure

Rewriting with PURE_ASM_REWRITE_RULE does not result in failure. It may diverge, in which case PURE_ONCE_ASM_REWRITE_RULE may be used.

See also

ASM_REWRITE_RULE, GEN_REWRITE_RULE, ONCE_REWRITE_RULE, PURE_REWRITE_RULE, PURE_ONCE_ASM_REWRITE_RULE.

PURE_ASM_REWRITE_TAC

PURE_ASM_REWRITE_TAC : (thm list -> tactic)

Synopsis

Rewrites a goal including the goal's assumptions as rewrites.

Description

PURE_ASM_REWRITE_TAC generates a set of rewrites from the supplied theorems and the assumptions of the goal, and applies these in a top-down recursive manner until no match is found. See GEN_REWRITE_TAC for more information on the group of rewriting tactics.

Failure

PURE_ASM_REWRITE_TAC does not fail, but it can diverge in certain situations. For limited depth rewriting, see PURE_ONCE_ASM_REWRITE_TAC. It can also result in an invalid tactic.

Uses

To advance or solve a goal when the current assumptions are expected to be useful in reducing the goal.

See also

ASM_REWRITE_TAC, GEN_REWRITE_TAC, FILTER_ASM_REWRITE_TAC, FILTER_ONCE_ASM_REWRITE_TAC, ONCE_ASM_REWRITE_TAC, ONCE_REWRITE_TAC, PURE_ONCE_ASM_REWRITE_TAC, PURE_ONCE_REWRITE_TAC, PURE_REWRITE_TAC, REWRITE_TAC, SUBST_TAC.

PURE_ONCE_ASM_REWRITE_RULE

PURE_ONCE_ASM_REWRITE_RULE : (thm list -> thm -> thm)

Synopsis

Rewrites a theorem once, including the theorem's assumptions as rewrites.

Description

PURE_ONCE_ASM_REWRITE_RULE excludes the basic tautologies in basic_rewrites from the theorems used for rewriting. It searches for matching subterms once only, without recursing over already rewritten subterms. For a general introduction to rewriting tools see GEN_REWRITE_RULE.

Failure

PURE_ONCE_ASM_REWRITE_RULE does not fail and does not diverge.

See also

ASM_REWRITE_RULE, GEN_REWRITE_RULE, ONCE_ASM_REWRITE_RULE, ONCE_REWRITE_RULE, PURE_ASM_REWRITE_RULE, PURE_REWRITE_RULE, REWRITE_RULE.

PURE_ONCE_ASM_REWRITE_TAC

PURE_ONCE_ASM_REWRITE_TAC : (thm list -> tactic)

Synopsis

Rewrites a goal once, including the goal's assumptions as rewrites.

342

Description

A set of rewrites generated from the assumptions of the goal and the supplied theorems is used to rewrite the term part of the goal, making only one pass over the goal. The basic tautologies are not included as rewrite theorems. The order in which the given theorems are applied is an implementation matter and the user should not depend on any ordering. See GEN_REWRITE_TAC for more information on rewriting tactics in general.

Failure

PURE_ONCE_ASM_REWRITE_TAC does not fail and does not diverge.

Uses

Manipulation of the goal by rewriting with its assumptions, in instances where rewriting with tautologies and recursive rewriting is undesirable.

See also

ASM_REWRITE_TAC, GEN_REWRITE_TAC, FILTER_ASM_REWRITE_TAC, FILTER_ONCE_ASM_REWRITE_TAC, ONCE_ASM_REWRITE_TAC, ONCE_REWRITE_TAC, PURE_ASM_REWRITE_TAC, PURE_ONCE_REWRITE_TAC, PURE_REWRITE_TAC, REWRITE_TAC, SUBST_TAC.

PURE_ONCE_REWRITE_CONV

PURE_ONCE_REWRITE_CONV : (thm list -> conv)

Synopsis

Rewrites a term once with only the given list of rewrites.

Description

PURE_ONCE_REWRITE_CONV generates rewrites from the list of theorems supplied by the user, without including the tautologies given in basic_rewrites. The applicable rewrites are employeded once, without entailing in a recursive search for matches over the term. See GEN_REWRITE_CONV for more details about rewriting strategies in HOL.

Failure

This rule does not fail, and it does not diverge.

See also

```
GEN_REWRITE_CONV, ONCE_DEPTH_CONV, ONCE_REWRITE_CONV, PURE_REWRITE_CONV, REWRITE_CONV.
```

PURE_ONCE_REWRITE_RULE

PURE_ONCE_REWRITE_RULE : (thm list -> thm -> thm)

Synopsis

Rewrites a theorem once with only the given list of rewrites.

Description

PURE_ONCE_REWRITE_RULE generates rewrites from the list of theorems supplied by the user, without including the tautologies given in basic_rewrites. The applicable rewrites are employeded once, without entailing in a recursive search for matches over the theorem. See GEN_REWRITE_RULE for more details about rewriting strategies in HOL.

Failure

This rule does not fail, and it does not diverge.

See also

ASM_REWRITE_RULE, GEN_REWRITE_RULE, ONCE_DEPTH_CONV, ONCE_REWRITE_RULE, PURE_REWRITE_RULE, REWRITE_RULE.

PURE_ONCE_REWRITE_TAC

PURE_ONCE_REWRITE_TAC : (thm list -> tactic)

Synopsis

Rewrites a goal using a supplied list of theorems, making one rewriting pass over the goal.

Description

PURE_ONCE_REWRITE_TAC generates a set of rewrites from the given list of theorems, and applies them at every match found through searching once over the term part of the goal, without recursing. It does not include the basic tautologies as rewrite theorems. The order in which the rewrites are applied is unspecified. For more information on rewriting tactics see GEN_REWRITE_TAC.

Failure

PURE_ONCE_REWRITE_TAC does not fail and does not diverge.

Uses

This tactic is useful when the built-in tautologies are not required as rewrite equations and recursive rewriting is not desired.

See also

ASM_REWRITE_TAC, GEN_REWRITE_TAC, FILTER_ASM_REWRITE_TAC, FILTER_ONCE_ASM_REWRITE_TAC, ONCE_ASM_REWRITE_TAC, ONCE_REWRITE_TAC, PURE_ASM_REWRITE_TAC, PURE_ONCE_ASM_REWRITE_TAC, PURE_REWRITE_TAC, REWRITE_TAC, SUBST_TAC.

PURE_REWRITE_CONV

PURE_REWRITE_CONV : (thm list -> conv)

Synopsis

Rewrites a term with only the given list of rewrites.

Description

This conversion provides a method for rewriting a term with the theorems given, and excluding simplification with tautologies in <code>basic_rewrites</code>. Matching subterms are found recursively, until no more matches are found. For more details on rewriting see <code>GEN_REWRITE_CONV</code>.

Uses

PURE_REWRITE_CONV is useful when the simplifications that arise by rewriting a theorem with basic_rewrites are not wanted.

Failure

Does not fail. May result in divergence, in which case PURE_ONCE_REWRITE_CONV can be used.

See also

GEN_REWRITE_CONV, ONCE_REWRITE_CONV, PURE_ONCE_REWRITE_CONV, REWRITE_CONV.

PURE_REWRITE_RULE

PURE_REWRITE_RULE : (thm list -> thm -> thm)

Synopsis

Rewrites a theorem with only the given list of rewrites.

Description

This rule provides a method for rewriting a theorem with the theorems given, and excluding simplification with tautologies in basic_rewrites. Matching subterms are found recursively starting from the term in the conclusion part of the theorem, until no more matches are found. For more details on rewriting see GEN_REWRITE_RULE.

Uses

PURE_REWRITE_RULE is useful when the simplifications that arise by rewriting a theorem with basic_rewrites are not wanted.

Failure

Does not fail. May result in divergence, in which case PURE_ONCE_REWRITE_RULE can be used.

See also

ASM_REWRITE_RULE, GEN_REWRITE_RULE, ONCE_REWRITE_RULE, PURE_ASM_REWRITE_RULE, PURE_ONCE_ASM_REWRITE_RULE, PURE_ONCE_REWRITE_RULE, REWRITE_RULE.

PURE_REWRITE_TAC

PURE_REWRITE_TAC : (thm list -> tactic)

Synopsis

Rewrites a goal with only the given list of rewrites.

Description

PURE_REWRITE_TAC behaves in the same way as REWRITE_TAC, but without the effects of the built-in tautologies. The order in which the given theorems are applied is an implementation matter and the user should not depend on any ordering. For more information on rewriting strategies see GEN_REWRITE_TAC.

Failure

PURE_REWRITE_TAC does not fail, but it can diverge in certain situations; in such cases PURE_ONCE_REWRITE_TAC may be used.

346

Uses

This tactic is useful when the built-in tautologies are not required as rewrite equations. It is sometimes useful in making more time-efficient replacements according to equations for which it is clear that no extra reduction via tautology will be needed. (The difference in efficiency is only apparent, however, in quite large examples.)

PURE_REWRITE_TAC advances goals but solves them less frequently than REWRITE_TAC; to be precise, PURE_REWRITE_TAC only solves goals which are rewritten to "T" (i.e. TRUTH) without recourse to any other tautologies.

Example

It might be necessary, say for subsequent application of an induction hypothesis, to resist reducing a term "b = T" to "b".

```
#PURE_REWRITE_TAC[]([],"b = T");;
([([], "b = T")], -) : subgoals
#REWRITE_TAC[]([],"b = T");;
([([], "b")], -) : subgoals
```

See also

ASM_REWRITE_TAC, FILTER_ASM_REWRITE_TAC, FILTER_ONCE_ASM_REWRITE_TAC, GEN_REWRITE_TAC, ONCE_ASM_REWRITE_TAC, ONCE_REWRITE_TAC, PURE_ASM_REWRITE_TAC, PURE_ONCE_ASM_REWRITE_TAC, PURE_ONCE_REWRITE_TAC, REWRITE_TAC, SUBST_TAC.

pure_ss

pureSimps.pure_ss : simpset

Synopsis

A simpset containing only the conditional rewrite generator and no additional rewrites.

Description

This simpset sits at the root of the simpset hierarchy. It contains no rewrites, congruences, conversions or decision procedures. Instead it contains just the code which converts theorems passed to it as context into (possibly conditional) rewrites.

Simplification with pure_ss is analogous to rewriting with PURE_REWRITE_TAC and others. The only difference is that the theorems passed to SIMP_TAC pure_ss are interpreted as conditional rewrite rules. Though the pure_ss can't take advantage of extra contextual information garnered through congruences, it can still discharge side conditions. (This is demonstrated in the examples below.)

Failure

Can't fail, as it is not a functional value.

Example

The theorem ADD_EQ_SUB from arithmeticTheory states that

 $|-!m n p. n \le p \Longrightarrow ((m + n = p) = m = p - n)$

We can use this result to make progress with the following goal in conjunction with pure_ss in a way that no form of REWRITE_TAC could:

- ASM_SIMP_TAC pure_ss [ADD_EQ_SUB] ([--'x <= y'--], --'z + x = y'--); > val it = ([(['x <= y'], 'z = y - x')], fn) : tactic_result

This example illustrates the way in which the simplifier can do conditional rewriting. However, the lack of the congruence for implications, means that using pure_ss will not be able to discharge the side condition in the goal below:

- SIMP_TAC pure_ss [ADD_EQ_SUB] ([], --'x <= y ==> (z + x = y)'--); > val it = ([([], 'x <= y ==> (z + x = y)')], fn) : tactic_result

As bool_ss has the relevant congruence included, it does make progress in the same situation:

- SIMP_TAC bool_ss [ADD_EQ_SUB] ([], --'x <= y ==> (z + x = y)'--); > val it = ([([], 'x <= y ==> (z = y - x)')], fn) : tactic_result

Uses

The pure_ss simpset might be used in the most delicate simplification situations, or, mimicking the way it is used within the distribution itself, as a basis for the construction of other simpsets.

Comments

There is also a PURE_ss ssdata value in the same pureSimps structure that I can't be bothered giving its own special manual entry. It plausibly doesn't need to be there at all.

See also

bool_ss, hol_ss, PURE_REWRITE_TAC, SIMP_CONV, SIMP_TAC

r

r : int -> unit

348

rand

Synopsis

Reorders the subgoals on top of the subgoal package goal stack.

Description

The function r is part of the subgoal package. It is an abbreviation for rotate. For a description of the subgoal package, see set_goal.

Failure

As for rotate.

Uses

Proving subgoals in a different order to that generated by the subgoal package.

See also

```
b, backup, backup_limit, e, expand, expandf, g, get_state, p, print_state,
rotate, save_top_thm, set_goal, set_state, top_goal, top_thm.
```

rand

rand : (term -> term)

Synopsis

Returns the operand from a combination (function application).

Description

rand "t1 t2" returns "t2".

Failure

Fails with rand if term is not a combination.

See also

rator, dest_comb.

RAND_CONV

RAND_CONV : (conv -> conv)

Synopsis

Applies a conversion to the operand of an application.

Description

If c is a conversion that maps a term "t2" to the theorem |-t2 = t2', then the conversion RAND_CONV c maps applications of the form "t1 t2" to theorems of the form:

|-(t1 t2) = (t1 t2')

That is, RAND_CONV c "t1 t2" applies c to the operand of the application "t1 t2".

Failure

RAND_CONV c tm fails if tm is not an application or if tm has the form "t1 t2" but the conversion c fails when applied to the term t2. The function returned by RAND_CONV c may also fail if the ML function c:term->thm is not, in fact, a conversion (i.e. a function that maps a term t to a theorem $|-t = t^{2}$).

Example

```
#RAND_CONV num_CONV "SUC 2";;
|- SUC 2 = SUC(SUC 1)
```

See also

ABS_CONV, BINOP_CONV, LAND_CONV, RATOR_CONV, SUB_CONV.

rator

rator : (term -> term)

Synopsis

Returns the operator from a combination (function application).

Description

rator("t1 t2") returns "t1".

Failure

Fails with rator if term is not a combination.

See also

rand, dest_comb.

350

RATOR_CONV

```
RATOR_CONV : (conv -> conv)
```

Synopsis

Applies a conversion to the operator of an application.

Description

If c is a conversion that maps a term "t1" to the theorem |-t1 = t1', then the conversion RATOR_CONV c maps applications of the form "t1 t2" to theorems of the form:

|-(t1 t2) = (t1' t2)

That is, RATOR_CONV c "t1 t2" applies c to the operand of the application "t1 t2".

Failure

RATOR_CONV c tm fails if tm is not an application or if tm has the form "t1 t2" but the conversion c fails when applied to the term t1. The function returned by RATOR_CONV c may also fail if the ML function c:term->thm is not, in fact, a conversion (i.e. a function that maps a term t to a theorem $|-t = t^{2}$).

Example

#RATOR_CONV BETA_CONV "(\x y. x + y) 1 2";; |- (\x y. x + y)1 2 = (\y. 1 + y)2

See also

ABS_CONV, RAND_CONV, SUB_CONV.

REDEPTH_CONV

REDEPTH_CONV : (conv -> conv)

Synopsis

Applies a conversion bottom-up to all subterms, retraversing changed ones.

Description

REDEPTH_CONV c tm applies the conversion c repeatedly to all subterms of the term tm and recursively applies REDEPTH_CONV c to each subterm at which c succeeds, until there is no subterm remaining for which application of c succeeds.

More precisely, REDEPTH_CONV c tm repeatedly applies the conversion c to all the subterms of the term tm, including the term tm itself. The supplied conversion c is applied to the subterms of tm in bottom-up order and is applied repeatedly (zero or more times, as is done by REPEATC) to each subterm until it fails. If c is successfully applied at least once to a subterm, t say, then the term into which t is transformed is retraversed by applying REDEPTH_CONV c to it.

Failure

REDEPTH_CONV c tm never fails but can diverge if the conversion c can be applied repeatedly to some subterm of tm without failing.

Example

The following example shows how REDEPTH_CONV retraverses subterms:

#REDEPTH_CONV BETA_CONV "(\f x. (f x) + 1) (\y.y) 2";; |- (\f x. (f x) + 1)(\y. y)2 = 2 + 1

Here, BETA_CONV is first applied successfully to the (beta-redex) subterm:

```
"(\f x. (f x) + 1) (\y.y)"
```

This application reduces this subterm to:

"(\x. ((\y.y) x) + 1)"

REDEPTH_CONV BETA_CONV is then recursively applied to this transformed subterm, eventually reducing it to "(x. x + 1)". Finally, a beta-reduction of the top-level term, now the simplified beta-redex "(x. x + 1) 2", produces "2 + 1".

Comments

The implementation of this function uses failure to avoid rebuilding unchanged subterms. That is to say, during execution the failure string 'QCONV' may be generated and later trapped. The behaviour of the function is dependent on this use of failure. So, if the conversion given as argument happens to generate a failure with string 'QCONV', the operation of REDEPTH_CONV will be unpredictable.

See also

DEPTH_CONV, ONCE_DEPTH_CONV, TOP_DEPTH_CONV.

REFINE_EXISTS_TAC

Q.REFINE_EXISTS_TAC : term quotation -> tactic

Synopsis

Attacks existential goals, making the existential variable more concrete.

Description

The tactic Q.REFINE_EXISTS_TAC q parses the quotation q in the context of the (necessarily existential) goal to which it is applied, and uses the resulting term as the witness for the goal. However, if the witness has any variables not already present in the goal, then these are treated as new existentially quantified variables. If there are no such "free" variables, then the behaviour is the same as EXISTS_TAC.

Failure

Fails if the goal is not existential, or if the quotation can not parse to a term of the same type as the existentially quantified variable.

Example

If the quotation doesn't mention any new variables:

```
- Q.REFINE_EXISTS_TAC 'n' ([''n > x''], ''?m. m > x'');
> val it =
    ([([''n > x''], ''n > x'')], fn)
    : (term list * term) list * (thm list -> thm)
```

If the quotation does mention any new variables, they are existentially quantified in the new goal:

```
- Q.REFINE_EXISTS_TAC 'n + 2' ([''~P 0''], ''?p. P (p - 1)'');
> val it =
    ([([''~P 0''], ''?n. P (n + 2 - 1)'')], fn)
    : (term list * term) list * (thm list -> thm)
```

Uses

Q.REFINE_EXISTS_TAC is useful if it is clear that a existential goal will be solved by a term of particular form, while it is not yet clear precisely what term this will be. Further proof activity should be able to exploit the additional structure that has appeared in the place of the existential variable.

EXISTS_TAC.

REFL

REFL : conv

Synopsis

Returns theorem expressing reflexivity of equality.

Description

REFL maps any term "t" to the corresponding theorem |-t = t.

Failure

Never fails.

See also

ALL_CONV, REFL_TAC.

REFL_TAC

REFL_TAC : tactic

Synopsis

Solves a goal which is an equation between alpha-equivalent terms.

Description

When applied to a goal A ?-t = t', where t and t' are alpha-equivalent, REFL_TAC completely solves it.

A ?- t = t' ======== REFL_TAC

Failure

Fails unless the goal is an equation between alpha-equivalent terms.

ACCEPT_TAC, MATCH_ACCEPT_TAC, REWRITE_TAC.

doc.

register_trace.doc

register_trace.doc : string -> int ref -> unit

Synopsis

Registers a new tracing variable.

Description

A call to register_trace n r registers the integer reference variable r as a tracing variable associated with name n. Its value at the time of registration is considered its default value, which will be restored by a call to reset_trace n or reset_traces.

Failure

Fails if there is already a tracing variable registered under the name given.

See also

current_trace, reset_trace, reset_traces, trace, traces.

remove_rules_for_term

Parse.remove_rules_for_term : string -> unit

Synopsis

Removes parsing/pretty-printing rules from the global grammar.

Description

Calling remove_rules_for_term s removes all those rules (if any) in the global grammar that are for the term s. The string specifies the name of the term that the rule is for, not a token that may happen to be used in concrete syntax for the term.

Failure

Never fails.

Example

The universal quantifier can have its special binder status removed using this function:

```
- val t = Term'!x. P x /\ ~Q x';
<<HOL message: inventing new type variable names: 'a.>>
> val t = '!x. P x /\ ~Q x' : Term.term
- remove_rules_for_term "!";
> val it = () : unit
- t;
> val it = '! (\x. P x /\ ~Q x)' : Term.term
```

Similarly, one can remove the two rules for conditional expressions and see the raw syntax as follows:

```
- val t = Term'if p then q else r';
<<HOL message: inventing new type variable names: 'a.>>
> val t = 'if p then q else r' : Term.term
- remove_rules_for_term "COND";
> val it = () : unit
- t;
> val it = 'COND p q r' : Term.term
```

Comments

There is a companion temp_remove_rules_for_term function, which has the same effect on the global grammar, but which does not cause this effect to persist when the current theory is exported.

See also

remove_termtok

remove_termtok

Parse.remove_termtok : {term_name : string, tok : string} -> unit

Synopsis

Removes a rule from the global grammar.

Description

The remove_termtok removes parsing/printing rules from the global grammar. Rules to be removed are those that are for the term with the given name (term_name) and which

include the string tok as part of their concrete representation. If multiple rules satisfy this criterion, they are all removed. If none match, the grammar is not changed.

Failure

Never fails.

Example

If one wished to revert to the traditional HOL syntax for conditional expressions, this would be achievable as follows:

```
- remove_termtok {term_name = "COND", tok = "if"};
> val it = () : unit
- Term'if p then q else r';
<<HOL message: inventing new type variable names: 'a, 'b, 'c, 'd, 'e, 'f.>>
> val it = 'if p then q else r' : Term.term
- Term'p => q | r';
<<HOL message: inventing new type variable names: 'a.>>
> val it = 'COND p q r' : Term.term
```

The second invocation of the parser above demonstrates that once the rule for the if-then-else syntax has been removed, a string that used to parse as a conditional expression then parses as a big function application (the function if applied to five arguments).

The fact that the pretty-printer does not print the term using the old-style syntax, even after the if-then-else rule has been removed, is due to the fact that the corresponding rule in the grammar does not have its preferred flag set. This can be accomplished with prefer_form_with_tok as follows:

```
- prefer_form_with_tok {term_name = "COND", tok = "=>"};
> val it = () : unit
- Term'p => q | r';
<<HOL message: inventing new type variable names: 'a.>>
> val it = 'p => q | r' : Term.term
```

Uses

Used to modify the global parsing/pretty-printing grammar by removing a rule, possibly as a prelude to adding another rule which would otherwise clash.

Comments

As with other functions in the Parse structure, there is a companion temp_remove_termtok function, which has the same effect on the global grammar, but which does not cause this effect to persist when the current theory is exported.

The specification of a rule by term_name and one of its tokens is not perfect, but seems adequate in practice.

remove_rules_for_term, prefer_form_with_tok

REPEAT

REPEAT : (tactic -> tactic)

Synopsis

Repeatedly applies a tactic until it fails.

Description

The tactic REPEAT T is a tactic which applies T to a goal, and while it succeeds, continues applying it to all subgoals generated.

Failure

The application of REPEAT to a tactic never fails, and neither does the composite tactic, even if the basic tactic fails immediately.

See also

EVERY, FIRST, ORELSE, THEN, THENL.

REPEATC

REPEATC : (conv -> conv)

Synopsis

Repeatedly apply a conversion (zero or more times) until it fails.

Description

If c is a conversion effects a transformation of a term t to a term t', that is if c maps t to the theorem |-t = t', then REPEATC c is the conversion that repeats this transformation as often as possible. More exactly, if c maps the term "ti" to |-ti=t(i+1) for i from 1 to n, but fails when applied to the n+1th term "t(n+1)", then REPEATC c "t1" returns |-t1 = t(n+1). And if c "t" fails, them REPEATC c "t" returns |-t = t.

Failure

Never fails, but can diverge if the supplied conversion never fails.

REPEAT_GTCL

REPEAT_GTCL : (thm_tactical -> thm_tactical)

Synopsis

Applies a theorem-tactical until it fails when applied to a goal.

Description

When applied to a theorem-tactical, a theorem-tactic, a theorem and a goal:

REPEAT_GTCL ttl ttac th goal

REPEAT_GTCL repeatedly modifies the theorem according to ttl till the result of handing it to ttac and applying it to the goal fails (this may be no times at all).

Failure

Fails iff the theorem-tactic fails immediately when applied to the theorem and the goal.

Example

The following tactic matches th's antecedents against the assumptions of the goal until it can do so no longer, then puts the resolvents onto the assumption list:

REPEAT_GTCL (IMP_RES_THEN ASSUME_TAC) th

See also

REPEAT_TCL, THEN_TCL.

REPEAT_TCL

REPEAT_TCL : (thm_tactical -> thm_tactical)

Synopsis

Repeatedly applies a theorem-tactical until it fails when applied to the theorem.

Description

When applied to a theorem-tactical, a theorem-tactic and a theorem:

REPEAT_TCL ttl ttac th

REPEAT_TCL repeatedly modifies the theorem according to ttl until it fails when given to the theorem-tactic ttac.

Failure

Fails iff the theorem-tactic fails immediately when applied to the theorem.

Example

It is often desirable to repeat the action of basic theorem-tactics. For example CHOOSE_THEN strips off a single existential quantification, so one might use REPEAT_TCL CHOOSE_THEN to get rid of them all.

Alternatively, one might want to repeatedly break apart a theorem which is a nested conjunction and apply the same theorem-tactic to each conjunct. For example the following goal:

?- ((0 = w) /\ (0 = x)) /\ (0 = y) /\ (0 = z) ==> (w + x + y + z = 0)

might be solved by

```
DISCH_THEN (REPEAT_TCL CONJUNCTS_THEN (SUBST1_TAC o SYM)) THEN REWRITE_TAC[ADD_CLAUSES]
```

See also

REPEAT_GTCL, THEN_TCL.

reset_trace

reset_trace : string -> unit

Synopsis

Resets a tracing variable to its default value.

Description

A call to reset_trace n resets the tracing variable associated with the name n to its default value, i.e., the value it had when it was registered.

Failure

Fails if the name given is not associated with a registered tracing variable.

See also

current_trace, register_trace, reset_traces, trace, traces.

360

reset_traces

.reset_traces : unit -> unit

Synopsis

Resets all registered tracing variables to their default values.

Failure

Never fails.

See also

current_trace, register_trace, reset_trace, trace, traces.

RES_CANON

RES_CANON : (thm -> thm list)

Synopsis

Put an implication into canonical form for resolution.

Description

All the HOL resolution tactics (e.g. IMP_RES_TAC) work by using modus ponens to draw consequences from an implicative theorem and the assumptions of the goal. Some of these tactics derive this implication from a theorem supplied explicitly the user (or otherwise from 'outside' the goal) and some obtain it from the assumptions of the goal itself. But in either case, the supplied theorem or assumption is first transformed into a list of implications in 'canonical' form by the function RES_CANON.

The theorem argument to RES_CANON should be either be an implication (which can be universally quantified) or a theorem from which an implication can be derived using the transformation rules discussed below. Given such a theorem, RES_CANON returns a list of implications in canonical form. It is the implications in this resulting list that are used by the various resolution tactics to infer consequences from the assumptions of a goal.

The transformations done by RES_CANON th to the theorem th are as follows. First, if th is a negation $A \mid - \tau$, this is converted to the implication $A \mid - \tau$ => F. The following inference rules are then applied repeatedly, until no further rule applies. Conjunctions

are split into their components and equivalence (boolean equality) is split into implication in both directions:

 $A \mid -t1 / t2$ $A \mid -t1 = t2$
 $A \mid -t1$ $A \mid -t2$
 $A \mid -t1 ==> t2$ $A \mid -t2 ==> t1$

Conjunctive antecedents are transformed by:

A |- (t1 /\ t2) ==> t A |- t1 ==> (t2 ==> t) A |- t2 ==> (t1 ==> t)

and disjunctive antecedents by:

A |- (t1 \/ t2) ==> t A |- t1 ==> t A |- t2 ==> t

The scope of universal quantifiers is restricted, if possible:

A |- !x. t1 ==> t2 ----- [if x is not free in t1] A |- t1 ==> !x. t2

and existentially-quantified antecedents are eliminated by:

A |- (?x. t1) ==> t2
------ [x' chosen so as not to be free in t2]
A |- !x'. t1[x'/x] ==> t2

Finally, when no further applications of the above rules are possible, and the theorem is an implication:

 $A \mid - !x1...xn. t1 ==> t2$

then the theorem A u {t1} \mid - t2 is transformed by a recursive application of RES_CANON to get a list of theorems:

[A u {t1} |- t21 ; ... ; A u {t1} |- t2n]

and the result of discharging t1 from these theorems:

[A |- !x1...xn. t1 ==> t21 ; ... ; A |- !x1...xn. t1 ==> t2n]

is returned. That is, the transformation rules are recursively applied to the conclusions of all implications.

Failure

RES_CANON th fails if no implication(s) can be derived from th using the transformation rules shown above.

Example

The uniqueness of the remainder ${\tt k}$ MOD ${\tt n}$ is expressed in HOL by the built-in theorem MOD_UNIQUE:

```
|-!n \ k \ r. (?q. (k = (q * n) + r) /\ r < n) ==> (k MOD n = r)
```

For this theorem, the canonical list of implications returned by RES_CANON is as follows:

```
#RES_CANON MOD_UNIQUE;;
[|- !k q n r. (k = (q * n) + r) ==> r < n ==> (k MOD n = r);
|- !r n. r < n ==> (!k q. (k = (q * n) + r) ==> (k MOD n = r))]
: thm list
```

The existentially-quantified, conjunctive, antecedent has given rise to two implications, and the scope of universal quantifiers has been restricted to the conclusions of the resulting implications wherever possible.

Uses

The primary use of RES_CANON is for the (internal) pre-processing phase of the built-in resolution tactics IMP_RES_TAC, IMP_RES_THEN, RES_TAC, and RES_THEN. But the function RES_CANON is also made available at top-level so that users can call it to see the actual form of the implications used for resolution in any particular case.

See also

```
IMP_RES_TAC, IMP_RES_THEN, RES_TAC, RES_THEN.
```

RES_TAC

RES_TAC : tactic

Synopsis

Enriches assumptions by repeatedly resolving them against each other.

Description

RES_TAC searches for pairs of assumed assumptions of a goal (that is, for a candidate implication and a candidate antecedent, respectively) which can be 'resolved' to yield new results. The conclusions of all the new results are returned as additional assumptions of the subgoal(s). The effect of RES_TAC on a goal is to enrich the assumptions set with some of its collective consequences.

When applied to a goal A ?- g, the tactic RES_TAC uses RES_CANON to obtain a set of implicative theorems in canonical form from the assumptions A of the goal. Each of the resulting theorems (if there are any) will have the form:

A |- u1 ==> u2 ==> ... ==> un ==> v

RES_TAC then tries to repeatedly 'resolve' these theorems against the assumptions of a goal by attempting to match the antecedents u1, u2, ..., un (in that order) to some assumption of the goal (i.e. to some candidate antecedents among the assumptions). If all the antecedents can be matched to assumptions of the goal, then an instance of the theorem

A u {a1,...,an} |- v

called a 'final resolvent' is obtained by repeated specialization of the variables in the implicative theorem, type instantiation, and applications of modus ponens. If only the first i antecedents u1, ..., ui can be matched to assumptions and then no further matching is possible, then the final resolvent is an instance of the theorem:

A u {a1,...,ai} |- u(i+1) ==> ... ==> v

All the final resolvents obtained in this way (there may be several, since an antecedent ui may match several assumptions) are added to the assumptions of the goal, in the stripped form produced by using STRIP_ASSUME_TAC. If the conclusion of any final resolvent is a contradiction 'F' or is alpha-equivalent to the conclusion of the goal, then RES_TAC solves the goal.

Failure

RES_TAC cannot fail and so should not be unconditionally REPEATEd. However, since the final resolvents added to the original assumptions are never used as 'candidate antecedents' it is sometimes necessary to apply RES_TAC more than once to derive the desired result.

See also

IMP_RES_TAC, IMP_RES_THEN, RES_CANON, RES_THEN.

RES_THEN

RES_THEN : (thm_tactic -> tactic)

Synopsis

Resolves all implicative assumptions against the rest.

Description

Like the basic resolution function IMP_RES_THEN, the resolution tactic RES_THEN performs a single-step resolution of an implication and the assumptions of a goal. RES_THEN differs from IMP_RES_THEN only in that the implications used for resolution are taken from the assumptions of the goal itself, rather than supplied as an argument.

When applied to a goal A ?- g, the tactic RES_THEN ttac uses RES_CANON to obtain a set of implicative theorems in canonical form from the assumptions A of the goal. Each of the resulting theorems (if there are any) will have the form:

ai |- !x1...xn. ui ==> vi

where ai is one of the assumptions of the goal. Having obtained these implications, RES_THEN then attempts to match each antecedent ui to each assumption $aj \mid -aj$ in the assumptions A. If the antecedent ui of any implication matches the conclusion aj of any assumption, then an instance of the theorem ai, $aj \mid -vi$, called a 'resolvent', is obtained by specialization of the variables x1, ..., xn and type instantiation, followed by an application of modus ponens. There may be more than one canonical implication derivable from the assumptions of the goal and each such implication is tried against every assumption, so there may be several resolvents (or, indeed, none).

Tactics are produced using the theorem-tactic ttac from all these resolvents (failures of ttac at this stage are filtered out) and these tactics are then applied in an unspecified sequence to the goal. That is,

RES_THEN ttac (A ?- g)

has the effect of:

```
MAP_EVERY (mapfilter ttac [... ; (ai,aj |- vi) ; ...]) (A ?- g)
```

where the theorems ai, aj |- vi are all the consequences that can be drawn by a (single) matching modus-ponens inference from the assumptions A and the implications derived using RES_CANON from the assumptions. The sequence in which the theorems ai, aj |- vi are generated and the corresponding tactics applied is unspecified.

Failure

Evaluating RES_THEN ttac th fails with 'no implication' if no implication(s) can be derived from the assumptions of the goal by the transformation process described under the entry for RES_CANON. Evaluating RES_THEN ttac (A ?- g) fails with 'no resolvents' if no assumption of the goal A ?- g can be resolved with the derived implication or implications. Evaluation also fails, with 'no tactics', if there are resolvents, but for every

resolvent ai,aj |- vi evaluating the application ttac (ai,aj |- vi) fails—that is, if for every resolvent ttac fails to produce a tactic. Finally, failure is propagated if any of the tactics that are produced from the resolvents by ttac fails when applied in sequence to the goal.

See also

IMP_RES_TAC, IMP_RES_THEN, MATCH_MP, RES_CANON, RES_TAC.

reveal

Parse.reveal : string -> unit

Synopsis

Restores recognition of a constant by the quotation parser.

Description

A call reveal "c", where c is a (perhaps) hidden constant, will unhide the constant, that is, will make the quotation parser recognize it as such rather than treating it as a variable. It reverses the effect of the call Parse.hide "c".

Failure

Never fails, but prints a warning message if the string does not correspond to an actual constant.

Comments

The hiding of a constant only affects the quotation parser; the constant is still there in a theory.

See also

Parse.hide, Parse.hidden.

rev_assoc

Compat.rev_assoc : ''a -> ('b * ''a) list -> ('b * ''a)

Synopsis

Searches a list of pairs for a pair whose second component equals a specified value.

Description

Found in the hol88 library. rev_assoc y [(x1,y1),...,(xn,yn)] returns the first (xi,yi) in the list such that yi equals y. The lookup is done on an eqtype, i.e., the SML implementation must be able to decide equality for the type of y.

Failure

Fails if no matching pair is found. This will always be the case if the list is empty. The function will not be available if the hol88 library has not been loaded.

Example

```
- rev_assoc 2 [(1,4),(3,2),(2,5),(2,6)];
(3, 2) : (int * int)
```

Comments

Not found in hol90, since we use an option type instead of exceptions.

assoc1; val it = fn : "a - $\dot{\epsilon}$ ("a * 'b) list - $\dot{\epsilon}$ ("a * 'b) option - assoc2; val it = fn : "a - $\dot{\epsilon}$ ('b * "a) list - $\dot{\epsilon}$ ('b * "a) option

See also

assoc, find, mem, tryfind, exists, forall.

rev_itlist

rev_itlist : ((* -> ** -> **) -> * list -> ** -> **)

Synopsis

Applies a binary function between adjacent elements of the reverse of a list.

Description

rev_itlist f [x1;...;xn] y returns f xn (... (f x2 (f x1 y))...). It returns y if the list is empty.

Failure

Never fails.

Example

#rev_itlist (\x y. x * y) [1;2;3;4] 1;;
24 : int

See also itlist, end_itlist.

rewrites

```
simpLib.rewrites : thm list -> ssdata
```

Synopsis

Creates an ssdata value consisting of the given theorems as rewrites.

Failure

Never fails.

Example

Instead of writing the simpler SIMP_CONV hol_ss thmlist, one could write

SIMP_CONV (hol_ss ++ rewrites thmlist) []

More plausibly, rewrites can be used to create commonly used ssdata values containing a great number of rewrites. This is how the basic system's various ssdata values are constructed where those values consist only of rewrite theorems.

See also

++, mk_simpset, SIMPSET, SIMP_CONV.

REWRITE_CONV

```
REWRITE_CONV : (thm list -> conv)
```

Synopsis

Rewrites a term including built-in tautologies in the list of rewrites.

Description

Rewriting a term using REWRITE_CONV utilizes as rewrites two sets of theorems: the tautologies in the ML list basic_rewrites and the ones supplied by the user. The rule searches top-down and recursively for subterms which match the left-hand side of any of the possible rewrites, until none of the transformations are applicable. There is no ordering specified among the set of rewrites.

Variants of this conversion allow changes in the set of equations used: PURE_REWRITE_CONV and others in its family do not rewrite with the theorems in basic_rewrites.

The top-down recursive search for matches may not be desirable, as this may increase the number of inferences being made or may result in divergence. In this case other rewriting tools such as ONCE_REWRITE_CONV and GEN_REWRITE_CONV can be used, or the set of theorems given may be reduced.

See GEN_REWRITE_CONV for the general strategy for simplifying theorems in HOL using equational theorems.

Failure

Does not fail, but may diverge if the sequence of rewrites is non-terminating.

Uses

Used to manipulate terms by rewriting them with theorems. While resulting in high degree of automation, REWRITE_CONV can spawn a large number of inference steps. Thus, variants such as PURE_REWRITE_CONV, or other rules such as SUBST_CONV, may be used instead to improve efficiency.

See also

```
basic_rewrites, GEN_REWRITE_CONV, ONCE_REWRITE_CONV, PURE_REWRITE_CONV,
REWR_CONV, SUBST_CONV.
```

REWRITE_RULE

REWRITE_RULE : (thm list -> thm -> thm)

Synopsis

Rewrites a theorem including built-in tautologies in the list of rewrites.

Description

Rewriting a theorem using REWRITE_RULE utilizes as rewrites two sets of theorems: the tautologies in the ML list basic_rewrites and the ones supplied by the user. The rule searches top-down and recursively for subterms which match the left-hand side of any of the possible rewrites, until none of the transformations are applicable. There is no ordering specified among the set of rewrites.

Variants of this rule allow changes in the set of equations used: PURE_REWRITE_RULE and others in its family do not rewrite with the theorems in basic_rewrites. Rules such as ASM_REWRITE_RULE add the assumptions of the object theorem (or a specified subset of these assumptions) to the set of possible rewrites.

The top-down recursive search for matches may not be desirable, as this may increase the number of inferences being made or may result in divergence. In this case other rewriting tools such as ONCE_REWRITE_RULE and GEN_REWRITE_RULE can be used, or the set of theorems given may be reduced.

See GEN_REWRITE_RULE for the general strategy for simplifying theorems in HOL using equational theorems.

Failure

Does not fail, but may diverge if the sequence of rewrites is non-terminating.

Uses

Used to manipulate theorems by rewriting them with other theorems. While resulting in high degree of automation, REWRITE_RULE can spawn a large number of inference steps. Thus, variants such as PURE_REWRITE_RULE, or other rules such as SUBST, may be used instead to improve efficiency.

See also

ASM_REWRITE_RULE, basic_rewrites, GEN_REWRITE_RULE, ONCE_REWRITE_RULE, PURE_REWRITE_RULE, REWR_CONV, REWRITE_CONV, SUBST.

REWRITE_TAC

```
REWRITE_TAC : (thm list -> tactic)
```

Synopsis

Rewrites a goal including built-in tautologies in the list of rewrites.

Description

Rewriting tactics in HOL provide a recursive left-to-right matching and rewriting facility that automatically decomposes subgoals and justifies segments of proof in which equational theorems are used, singly or collectively. These include the unfolding of definitions, and the substitution of equals for equals. Rewriting is used either to advance or to complete the decomposition of subgoals.

REWRITE_TAC transforms (or solves) a goal by using as rewrite rules (i.e. as left-to-right replacement rules) the conclusions of the given list of (equational) theorems, as well as a set of built-in theorems (common tautologies) held in the ML variable basic_rewrites. Recognition of a tautology often terminates the subgoaling process (i.e. solves the goal).

The equational rewrites generated are applied recursively and to arbitrary depth, with matching and instantiation of variables and type variables. A list of rewrites can set off an infinite rewriting process, and it is not, of course, decidable in general whether a

rewrite set has that property. The order in which the rewrite theorems are applied is unspecified, and the user should not depend on any ordering.

See GEN_REWRITE_TAC for more details on the rewriting process. Variants of REWRITE_TAC allow the use of a different set of rewrites. Some of them, such as PURE_REWRITE_TAC, exclude the basic tautologies from the possible transformations. ASM_REWRITE_TAC and others include the assumptions at the goal in the set of possible rewrites.

Still other tactics allow greater control over the search for rewritable subterms. Several of them such as ONCE_REWRITE_TAC do not apply rewrites recursively. GEN_REWRITE_TAC allows a rewrite to be applied at a particular subterm.

Failure

REWRITE_TAC does not fail. Certain sets of rewriting theorems on certain goals may cause a non-terminating sequence of rewrites. Divergent rewriting behaviour results from a term t being immediately or eventually rewritten to a term containing t as a sub-term. The exact behaviour depends on the HOL implementation.

Example

The arithmetic theorem GREATER_DEF, |- |m n. m > n = n < m, is used below to advance a goal:

- REWRITE_TAC [GREATER_DEF] ([], '`5 > 4''); > ([([], '`4 < 5'')], -) : subgoals</pre>

It is used below with the theorem LESS_0, |- !n. 0 < (SUC n), to solve a goal:

```
- val (gl,p) =
    REWRITE_TAC [GREATER_DEF, LESS_0] ([], ' (SUC n) > 0 ' );
> val gl = [] : goal list
> val p = fn : proof
- p[];
> val it = |- (SUC n) > 0 : thm
```

Uses

Rewriting is a powerful and general mechanism in HOL, and an important part of many proofs. It relieves the user of the burden of directing and justifying a large number of minor proof steps. REWRITE_TAC fits a forward proof sequence smoothly into the general goal-oriented framework. That is, (within one subgoaling step) it produces and justifies certain forward inferences, none of which are necessarily on a direct path to the desired goal.

REWRITE_TAC may be more powerful a tactic than is needed in certain situations; if efficiency is at stake, alternatives might be considered. On the other hand, if more power is required, the simplification functions (SIMP_TAC and others) may be appropriate.

ASM_REWRITE_TAC, GEN_REWRITE_TAC, FILTER_ASM_REWRITE_TAC, FILTER_ONCE_ASM_REWRITE_TAC, ONCE_ASM_REWRITE_TAC, ONCE_REWRITE_TAC, PURE_ASM_REWRITE_TAC, PURE_ONCE_ASM_REWRITE_TAC, PURE_ONCE_REWRITE_TAC, PURE_REWRITE_TAC, REWR_CONV, REWRITE_CONV, SIMP_TAC, SUBST_TAC.

REWR_CONV

REWR_CONV : (thm -> conv)

Synopsis

Uses an instance of a given equation to rewrite a term.

Description

REWR_CONV is one of the basic building blocks for the implementation of rewriting in the HOL system. In particular, the term replacement or rewriting done by all the built-in rewriting rules and tactics is ultimately done by applications of REWR_CONV to appropriate subterms. The description given here for REWR_CONV may therefore be taken as a specification of the atomic action of replacing equals by equals that is used in all these higher level rewriting tools.

The first argument to REWR_CONV is expected to be an equational theorem which is to be used as a left-to-right rewrite rule. The general form of this theorem is:

 $A \mid -t[x1,...,xn] = u[x1,...,xn]$

where x1, ..., xn are all the variables that occur free in the left-hand side of the conclusion of the theorem but do not occur free in the assumptions. Any of these variables may also be universally quantified at the outermost level of the equation, as for example in:

A |-!x1...xn. t[x1,...,xn] = u[x1,...,xn]

Note that REWR_CONV will also work, but will give a generally undesirable result (see below), if the right-hand side of the equation contains free variables that do not also occur free on the left-hand side, as for example in:

A |-t[x1,...,xn] = u[x1,...,xn,y1,...,ym]

where the variables y1, ..., ym do not occur free in t[x1,...,xn].

372

If th is an equational theorem of the kind shown above, then REWR_CONV th returns a conversion that maps terms of the form t[e1,...,en/x1,...,xn], in which the terms e1, ..., en are free for x1, ..., xn in t, to theorems of the form:

A |- t[e1,...,en/x1,...,xn] = u[e1,...,en/x1,...,xn]

That is, REWR_CONV th tm attempts to match the left-hand side of the rewrite rule th to the term tm. If such a match is possible, then REWR_CONV returns the corresponding substitution instance of th.

If REWR_CONV is given a theorem th:

$$A \mid -t[x1,...,xn] = u[x1,...,xn,y1,...,ym]$$

where the variables y1, ..., ym do not occur free in the left-hand side, then the result of applying the conversion REWR_CONV th to a term t[e1,...,en/x1,...,xn] will be:

A |- t[e1,...,en/x1,...,xn] = u[e1,...,en,v1,...,vm/x1,...,xn,y1,...,ym]

where v1, ..., vm are variables chosen so as to be free nowhere in th or in the input term. The user has no control over the choice of the variables v1, ..., vm, and the variables actually chosen may well be inconvenient for other purposes. This situation is, however, relatively rare; in most equations the free variables on the right-hand side are a subset of the free variables on the left-hand side.

In addition to doing substitution for free variables in the supplied equational theorem (or 'rewrite rule'), REWR_CONV th tm also does type instantiation, if this is necessary in order to match the left-hand side of the given rewrite rule th to the term argument tm. If, for example, th is the theorem:

 $A \mid -t[x1,...,xn] = u[x1,...,xn]$

and the input term tm is (a substitution instance of) an instance of t[x1,...,xn] in which the types ty1, ..., tyi are substituted for the type variables vty1, ..., vtyi, that is if:

tm = t[ty1,...,tyn/vty1,...,vtyn][e1,...,en/x1,...,xn]

then REWR_CONV th tm returns:

A |- (t = u)[ty1,...,tyn/vty1,...,vtyn][e1,...,en/x1,...,xn]

Note that, in this case, the type variables vty1, ..., vtyi must not occur anywhere in the hypotheses A. Otherwise, the conversion will fail.

Failure

REWR_CONV th fails if th is not an equation or an equation universally quantified at the outermost level. If th is such an equation:

th = A |-!v1...,vi.t[x1,...,xn] = u[x1,...,xn,y1,...,yn]

then REWR_CONV th tm fails unless the term tm is alpha-equivalent to an instance of the left-hand side t[x1,...,xn] which can be obtained by instantiation of free type variables (i.e. type variables not occurring in the assumptions A) and substitution for the free variables x1, ..., xn.

Example

The following example illustrates a straightforward use of REWR_CONV. The supplied rewrite rule is polymorphic, and both substitution for free variables and type instantiation may take place. EQ_SYM_EQ is the theorem:

|-!x:*.!y.(x = y) = (y = x)

and REWR_CONV EQ_SYM behaves as follows:

#REWR_CONV EQ_SYM_EQ "1 = 2";; |- (1 = 2) = (2 = 1) #REWR_CONV EQ_SYM_EQ "1 < 2";; evaluation failed REWR_CONV: lhs of theorem doesn't match term

The second application fails because the left-hand side "x = y" of the rewrite rule does not match the term to be rewritten, namely "1 < 2".

In the following example, one might expect the result to be the theorem $A \mid -f 2 = 2$, where A is the assumption of the supplied rewrite rule:

#REWR_CONV (ASSUME "!x:*. f x = x") "f 2:num";;
evaluation failed REWR_CONV: lhs of theorem doesn't match term

The application fails, however, because the type variable * appears in the assumption of the theorem returned by ASSUME "!x:*. f x = x".

Failure will also occur in situations like:

#REWR_CONV (ASSUME "f (n:num) = n") "f 2:num";;
evaluation failed REWR_CONV: lhs of theorem doesn't match term

where the left-hand side of the supplied equation contains a free variable (in this case n) which is also free in the assumptions, but which must be instantiated in order to match the input term.

374

REWRITE_CONV.

rhs

rhs : (term -> term)

Synopsis

Returns the right-hand side of an equation.

Description

rhs "t1 = t2" returns "t2".

Failure

Fails with rhs if term is not an equality.

See also

lhs, dest_eq.

RIGHT_AND_EXISTS_CONV

RIGHT_AND_EXISTS_CONV : conv

Synopsis

Moves an existential quantification of the right conjunct outwards through a conjunction.

Description

When applied to a term of the form P / (?x.Q), the conversion RIGHT_AND_EXISTS_CONV returns the theorem:

|-P / (?x.Q) = (?x'. P / (Q[x'/x]))

where x, is a primed variant of x that does not appear free in the input term.

Failure

Fails if applied to a term not of the form P / (?x.Q).

AND_EXISTS_CONV, EXISTS_AND_CONV, LEFT_AND_EXISTS_CONV.

RIGHT_AND_FORALL_CONV

RIGHT_AND_FORALL_CONV : conv

Synopsis

Moves a universal quantification of the right conjunct outwards through a conjunction.

Description

When applied to a term of the form P / (!x.Q), the conversion RIGHT_AND_FORALL_CONV returns the theorem:

|-P / (!x.Q) = (!x'. P / (Q[x'/x]))

where x, is a primed variant of x that does not appear free in the input term.

Failure

Fails if applied to a term not of the form P / (!x.Q).

See also

AND_FORALL_CONV, FORALL_AND_CONV, LEFT_AND_FORALL_CONV.

RIGHT_BETA

RIGHT_BETA : (thm -> thm)

Synopsis

Beta-reduces a top-level beta-redex on the right-hand side of an equation.

Description

When applied to an equational theorem, RIGHT_BETA applies beta-reduction at top level to the right-hand side (only). Variables are renamed if necessary to avoid free variable

capture.

```
A |- s = (\x. t1) t2
----- RIGHT_BETA
A |- s = t1[t2/x]
```

Failure

Fails unless the theorem is equational, with its right-hand side being a top-level beta-redex.

See also

BETA_CONV, BETA_RULE, BETA_TAC, RIGHT_LIST_BETA.

RIGHT_CONV_RULE

RIGHT_CONV_RULE : (conv -> thm -> thm)

Synopsis

Applies a conversion to the right-hand side of an equational theorem.

Description

If c is a conversion that maps a term "t2" to the theorem |-t2 = t2', then the rule RIGHT_CONV_RULE c infers |-t1 = t2' from the theorem |-t1 = t2. That is, if c "t2" returns A' |-t2 = t2', then:

```
A |- t1 = t2
----- RIGHT_CONV_RULE c
A u A' |- t1 = t2'
```

Note that if the conversion c returns a theorem with assumptions, then the resulting inference rule adds these to the assumptions of the theorem it returns.

Failure

RIGHT_CONV_RULE c th fails if the conclusion of the theorem th is not an equation, or if th is an equation but c fails when applied its right-hand side. The function returned by RIGHT_CONV_RULE c will also fail if the ML function c:term->thm is not, in fact, a conversion (i.e. a function that maps a term t to a theorem |-t = t').

See also CONV_RULE.

RIGHT_IMP_EXISTS_CONV

RIGHT_IMP_EXISTS_CONV : conv

Synopsis

Moves an existential quantification of the consequent outwards through an implication.

Description

When applied to a term of the form P ==> (?x.Q), the conversion RIGHT_IMP_EXISTS_CONV returns the theorem:

|-P ==> (?x.Q) = (?x'.P ==> (Q[x'/x]))

where x, is a primed variant of x that does not appear free in the input term.

Failure

Fails if applied to a term not of the form $P \implies (?x.Q)$.

See also

EXISTS_IMP_CONV, LEFT_IMP_FORALL_CONV.

RIGHT_IMP_FORALL_CONV

RIGHT_IMP_FORALL_CONV : conv

Synopsis

Moves a universal quantification of the consequent outwards through an implication.

Description

When applied to a term of the form P ==> (!x.Q), the conversion RIGHT_IMP_FORALL_CONV returns the theorem:

|-P ==> (!x.Q) = (!x'.P ==> (Q[x'/x]))

where x, is a primed variant of x that does not appear free in the input term.

Failure

Fails if applied to a term not of the form $P \implies (!x.Q)$.

FORALL_IMP_CONV, LEFT_IMP_EXISTS_CONV.

RIGHT_LIST_BETA

RIGHT_LIST_BETA : (thm -> thm)

Synopsis

Iteratively beta-reduces a top-level beta-redex on the right-hand side of an equation.

Description

When applied to an equational theorem, RIGHT_LIST_BETA applies beta-reduction over a top-level chain of beta-redexes to the right hand side (only). Variables are renamed if necessary to avoid free variable capture.

A |- s = (\x1...xn. t) t1 ... tn
------ RIGHT_LIST_BETA
A |- s = t[t1/x1]...[tn/xn]

Failure

Fails unless the theorem is equational, with its right-hand side being a top-level betaredex.

See also

BETA_CONV, BETA_RULE, BETA_TAC, LIST_BETA_CONV, RIGHT_BETA.

RIGHT_OR_EXISTS_CONV

RIGHT_OR_EXISTS_CONV : conv

Synopsis

Moves an existential quantification of the right disjunct outwards through a disjunction.

Description

When applied to a term of the form $P \setminus / (?x.Q)$, the conversion RIGHT_OR_EXISTS_CONV returns the theorem:

 $|-P \setminus (?x.Q) = (?x'. P \setminus (Q[x'/x]))$

where $x^{,i}$ is a primed variant of x that does not appear free in the input term.

Failure

Fails if applied to a term not of the form $P \setminus / (?x.Q)$.

See also

OR_EXISTS_CONV, EXISTS_OR_CONV, LEFT_OR_EXISTS_CONV.

RIGHT_OR_FORALL_CONV

RIGHT_OR_FORALL_CONV : conv

Synopsis

Moves a universal quantification of the right disjunct outwards through a disjunction.

Description

When applied to a term of the form $P \setminus / (!x.Q)$, the conversion RIGHT_OR_FORALL_CONV returns the theorem:

 $|-P \setminus (!x.Q) = (!x'. P \setminus (Q[x'/x]))$

where x, is a primed variant of x that does not appear free in the input term.

Failure

Fails if applied to a term not of the form $P \setminus (!x.Q)$.

See also

OR_FORALL_CONV, FORALL_OR_CONV, LEFT_OR_FORALL_CONV.

Rsyntax

Rsyntax

Synopsis

A structure that restores a record-style environment for term manipulation.

Description

If one has opened the Psyntax structure, one can open the Rsyntax structure to get record-style functions back.

380

Each function in the Rsyntax structure has a corresponding function in the Psyntax structure, and vice versa. One can flip-flop between the two structures by opening one and then the other. One can also use long identifiers in order to use both syntaxes at once.

Failure

Never fails.

Example

The following shows how to open the Rsyntax structure and the functions that subsequently become available in the top level environment. Documentation for each of these functions is available online.

```
- open Rsyntax;
open Rsyntax
val INST = fn : term subst -> thm -> thm
val INST_TYPE = fn : hol_type subst -> thm -> thm
val INST_TY_TERM = fn : term subst * hol_type subst -> thm -> thm
val SUBST = fn : {thm:thm, var:term} list -> term -> thm -> thm
val SUBST_CONV = fn : {thm:thm, var:term} list -> term -> thm
val define_new_type_bijections = fn
  : {ABS:string, REP:string, name:string, tyax:thm} -> thm
val dest_abs = fn : term -> {Body:term, Bvar:term}
val dest_comb = fn : term -> {Rand:term, Rator:term}
val dest_cond = fn : term -> {cond:term, larm:term, rarm:term}
val dest_conj = fn : term -> {conj1:term, conj2:term}
val dest_cons = fn : term -> {hd:term, tl:term}
val dest_const = fn : term -> {Name:string, Ty:hol_type}
val dest_disj = fn : term -> {disj1:term, disj2:term}
val dest_eq = fn : term -> {lhs:term, rhs:term}
val dest_exists = fn : term -> {Body:term, Bvar:term}
val dest_forall = fn : term -> {Body:term, Bvar:term}
val dest_imp = fn : term -> {ant:term, conseq:term}
val dest_let = fn : term -> {arg:term, func:term}
val dest_list = fn : term -> {els:term list, ty:hol_type}
val dest_pabs = fn : term -> {body:term, varstruct:term}
val dest_pair = fn : term -> {fst:term, snd:term}

RULE_ASSUM_TAC

RULE_ASSUM_TAC : ((thm -> thm) -> tactic)

Synopsis

Maps an inference rule over the assumptions of a goal.

Description

When applied to an inference rule f and a goal ({A1;...;An} ?- t), the RULE_ASSUM_TAC tactical applies the inference rule to each of the ASSUMEd assumptions to give a new goal.

Failure

The application of RULE_ASSUM_TAC f to a goal fails iff f fails when applied to any of the assumptions of the goal.

Comments

It does not matter if the goal has no assumptions, but in this case RULE_ASSUM_TAC has no effect.

See also

ASSUM_LIST, MAP_EVERY, MAP_FIRST, POP_ASSUM_LIST.

S

S : ((* -> ** -> ***) -> (* -> **) -> * -> ***)

Synopsis

Performs function composition: S f g x = f x (g x) (the S combinator).

Failure

Never fails.

See also

#, B, C, CB, Co, I, K, KI, o, oo, W.

save_thm

save_thm : ((string # thm) -> thm)

Synopsis

Stores a theorem in the current theory segment.

Description

The call save_thm('name', th) adds the theorem th to the current theory segment under the name name. The theorem is returned as a value. The call can be made in both proof and draft mode. The name name must be a distinct name within the theory segment, but may be the same as for items within other theory segments of the theory. If the current theory segment is named thy, the theorem will be written to the file thy.th in the directory from which HOL was called. If the system is in draft mode, other changes made to the current theory segment during the session will also be written to the theory file. If the theory file does not exist, it will be created.

Failure

A call to save_thm will fail if the name given is the same as the name of an existing fact in the current theory segment. Saving the theorem involves writing to the file system. If the write fails for any reason save_thm will fail. For example, on start up the initial theory is HOL. The associated theory files are read-only so an attempt to save a theorem in that theory segment will fail.

Uses

Adding theorems to the current theory. Saving theorems for retrieval in later sessions. The theorem may be retrieved using the function theorem. Binding the result of save_thm to an ML variable makes it easy to access the theorem in the current terminal session.

See also

new_theory, prove_thm, save_top_thm, theorem.

SELECT_CONV

SELECT_CONV : conv

Synopsis

Eliminates an epsilon term by introducing an existential quantifier.

Description

The conversion SELECT_CONV expects a boolean term of the form "P[@x.P[x]/x]", which asserts that the epsilon term @x.P[x] denotes a value, x say, for which P[x] holds. This assertion is equivalent to saying that there exists such a value, and SELECT_CONV applied to a term of this form returns the theorem |-P[@x.P[x]/x] = ?x. P[x].

Failure

Fails if applied to a term that is not of the form "P[@x.P[x]/x]".

Example

#SELECT_CONV "(@n. n < m) < m";; |- (@n. n < m) < m = (?n. n < m)</pre>

Uses

Particularly useful in conjunction with CONV_TAC for proving properties of values denoted by epsilon terms. For example, suppose that one wishes to prove the goal

["0 < m"], "(@n. n < m) < SUC m"

Using the built-in arithmetic theorem

LESS_SUC |- !m n. m < n => m < (SUC n)

this goal may be reduced by the tactic MATCH_MP_TAC LESS_SUC to the subgoal

["0 < m"], "(@n. n < m) < m"

This is now in the correct form for using CONV_TAC SELECT_CONV to eliminate the epsilon term, resulting in the existentially quantified goal

["0 < m"], "?n. n < m"

which is then straightforward to prove.

See also

SELECT_ELIM, SELECT_INTRO, SELECT_RULE.

SELECT_ELIM

SELECT_ELIM : (thm -> (term # thm) -> thm)

Synopsis

Eliminates an epsilon term, using deduction from a particular instance.

Description

SELECT_ELIM expects two arguments, a theorem th1, and a pair (v,th2):(term # thm). The conclusion of th1 must have the form P(\$@ P), which asserts that the epsilon term \$@ P denotes some value at which P holds. The variable v appears only in the assumption P v of the theorem th2. The conclusion of the resulting theorem matches that of th2, and the hypotheses include the union of all hypotheses of the premises excepting P v.

A1 |- P(\$@ P) A2 u {P v} |- t ----- SELECT_ELIM th1 (v,th2) A1 u A2 |- t

where v is not free in A2. If v appears in the conclusion of th2, the epsilon term will NOT be eliminated, and the conclusion will be t[\$0 P/v].

Failure

Fails if the first theorem is not of the form A1 |-P(\$@ P), or if the variable v occurs free in any other assumption of th2.

Example

If a property of functions is defined by:

INCR = |- !f. INCR f = (!t1 t2. t1 < t2 ==> (f t1) < (f t2))

The following theorem can be proved.

th1 = |- INCR(@f. INCR f)

Additionally, if such a function is assumed to exist, then one can prove that there also exists a function which is injective (one-to-one) but not surjective (onto).

th2 = [INCR g] |- ?h. ONE_ONE h /\ ~ONTO h

These two results may be combined using SELECT_ELIM to give a new theorem:

```
#SELECT_ELIM th1 ("g:num->num", th2);;
|- ?h. ONE_ONE h /\ ~ONTO h
```

Uses

This rule is rarely used. The equivalence of P(\$@ P) and \$? P makes this rule fundamentally similar to the ?-elimination rule CHOOSE.

CHOOSE, SELECT_AX, SELECT_CONV, SELECT_INTRO, SELECT_RULE.

SELECT_EQ

SELECT_EQ : (term -> thm -> thm)

Synopsis

Applies epsilon abstraction to both terms of an equation.

Description

Effects the extensionality of the epsilon operator @.

A |- t1 = t2 ----- SELECT_EQ "x" [where x is not free in A] A |- (@x.t1) = (@x.t2)

Failure

Fails if the conclusion of the theorem is not an equation, or if the variable x is free in A.

Example

Given a theorem which shows the equivalence of two distinct forms of defining the property of being an even number:

th = $|-(x \mod 2 = 0) = (?y. x = 2 * y)$

A theorem giving the equivalence of the epsilon abstraction of each form is obtained:

#SELECT_EQ "x:num" th;; |- (@x. x MOD 2 = 0) = (@x. ?y. x = 2 * y)

See also

ABS, AP_TERM, EXISTS_EQ, FORALL_EQ, SELECT_AX, SELECT_CONV, SELECT_ELIM, SELECT_INTRO.

SELECT_INTRO

SELECT_INTRO : (thm -> thm)

Synopsis

Introduces an epsilon term.

Description

SELECT_INTRO takes a theorem with an applicative conclusion, say $P \times x$, and returns a theorem with the epsilon term Q P = 0 in place of the original operand x.

A |- P x ----- SELECT_INTRO A |- P(\$@ P)

The returned theorem asserts that \$0 P denotes some value at which P holds.

Failure

Fails if the conclusion of the theorem is not an application.

Example

Given the theorem

 $th1 = |- (\langle n. m = n \rangle)m$

applying SELECT_INTRO replaces the second occurrence of m with the epsilon abstraction of the operator:

#let th2 = SELECT_INTRO th1;; th2 = |- (\n. m = n)(@n. m = n)

This theorem could now be used to derive a further result:

#EQ_MP(BETA_CONV(concl th2))th2;; |- m = (@n. m = n)

See also

EXISTS, SELECT_AX, SELECT_CONV, SELECT_ELIM, SELECT_RULE.

SELECT_RULE

SELECT_RULE : (thm -> thm)

Synopsis

Introduces an epsilon term in place of an existential quantifier.

Description

The inference rule SELECT_RULE expects a theorem asserting the existence of a value x such that P holds. The equivalent assertion that the epsilon term @x.P denotes a value of x for which P holds is returned as a theorem.

A |- ?x. P ----- SELECT_RULE A |- P[(@x.P)/x]

Failure

Fails if applied to a theorem the conclusion of which is not existentially quantified.

Example

The axiom INFINITY_AX in the theory ind is of the form:

|- ?f. ONE_ONE f /\ ~ONTO f

Applying SELECT_RULE to this theorem returns the following.

```
#SELECT_RULE INFINITY_AX;;
|- ONE_ONE(@f. ONE_ONE f /\ ~ONTO f) /\ ~ONTO(@f. ONE_ONE f /\ ~ONTO f)
```

Uses

May be used to introduce an epsilon term to permit rewriting with a constant defined using the epsilon operator.

See also

CHOOSE, SELECT_AX, SELECT_CONV, SELECT_ELIM, SELECT_INTRO.

setify

Compat.setify : ''a list -> ''a list

Synopsis

setify makes a set out of an "eqtype" list.

Description

Found in the hol88 library. setify 1 removes repeated elements from 1, leaving the last occurrence of each duplicate in the list.

Failure

Never fails. The function is not available unless the hol88 library has been loaded.

Example

- setify [1,2,3,1,4,3]; [2,1,4,3] : int list

Comments

Perhaps the first occurrence of each duplicate should be left in the list, not the last? However, other functions may rely on the ordering currently used. Included in Compat because setify is not found in hol90 (mk_set is used instead.)

See also

distinct.

set_backup

goalstackLib.set_backup : int -> unit

Synopsis

Limits the number of proof states saved on the subgoal package backup list.

Description

The assignable variable set_backup is initially set to 12. Its value is one less than the maximum number of proof states that may be saved on the backup list. Adding a new proof state (by, for example, a call to expand) after the maximum is reached causes the earliest proof state on the list to be discarded. For a description of the subgoal package, see set_goal.

390

Example

```
#set_backup 0;
() unit
#g "(HD[1;2;3] = 1) /\ (TL[1;2;3] = [2;3])";;
"(HD[1;2;3] = 1) /\ (TL[1;2;3] = [2;3])"
() : void
#e CONJ_TAC;;
OK..
2 subgoals
"TL[1;2;3] = [2;3]"
"HD[1;2;3] = 1"
() : void
#e (REWRITE_TAC[HD]);;
OK..
goal proved
|-HD[1;2;3] = 1
Previous subproof:
"TL[1;2;3] = [2;3]"
() : void
#b();;
2 subgoals
"TL[1;2;3] = [2;3]"
"HD[1;2;3] = 1"
() : void
#b();;
evaluation failed backup: backup list is empty
```

See also

b, backup, e, expand, expandf, g, get_state, p, print_state, r, rotate, save_top_thm, set_goal, set_state, top_goal, top_thm.

set_fixity

Parse.set_fixity : string -> fixity -> unit

Synopsis

Allows the fixity of tokens to be updated.

Description

The set_fixity function is used to change the fixity of single tokens. It implements this functionality rather crudely. When called on to set the fixity of t to f, it removes all rules mentioning t from the global (term) grammar, and then adds a new rule to the grammar. The new rule maps occurrences of t with the given fixity to terms of the same name.

Failure

This function fails if the new fixity causes a clash with existing rules, as happens if the precedence level of the specified fixity is already taken by rules using a fixity of a different type. Even though the application of set_fixity may succeed, it may also cause the first subsequent application of the Term parsing function to fail. This latter will happen if the new rule causes a conflict in the precedence matrix.

Example

After a new constant is defined, set_fixity can be used to give them appropriate fixities:

The same function can be used to alter the fixities of existing constants:

- val t = Term'2 + 3 + 4 - 6'; > val t = '2 + 3 + 4 - 6' : Term.term - set_fixity "+" (Infixr 501); > val it = () : unit - t; > val it = '(2 + 3) + 4 - 6' : Term.term - dest_comb (Term'3 - 1 + 2'); > val it = ('\$- 3', '1 + 2') : Term.term * Term.term

Comments

This function is of no use if multiple-token rules (such as those for conditional expressions) are desired, or if the token does not correspond to the name of the constant or variable that is to be produced.

As with other functions in the Parse structure, there is a companion temp_set_fixity function, which has the same effect on the global grammar, but which does not cause this effect to persist when the current theory is exported.

See also

add_rule, add_infix, remove_rules_for_term, remove_termtok

set_goal

Synopsis

Initializes the subgoal package with a new goal.

Description

The function set_goal initializes the subgoal management package. A proof state of the package consists of either a goal stack and a justification stack if a proof is in progress, or a theorem if a proof has just been completed. set_goal sets a new proof state consisting of an empty justification stack and a goal stack with the given goal as its sole goal. The goal is printed.

Failure

Fails unless all terms in the goal are of type bool.

Example

```
#set_goal([], "(HD[1;2;3] = 1) /\ (TL[1;2;3] = [2;3])");;
"(HD[1;2;3] = 1) /\ (TL[1;2;3] = [2;3])"
```

```
() : void
```

Uses

Starting an interactive proof session with the subgoal package.

The subgoal package implements a simple framework for interactive goal-directed proof. When conducting a proof that involves many subgoals and tactics, the user must keep track of all the justifications and compose them in the correct order. While this is feasible even in large proofs, it is tedious. The subgoal package provides a way of building and traversing the tree of subgoals top-down, stacking the justifications and applying them properly.

The package maintains a proof state consisting of either a goal stack of outstanding goals and a justification stack, or a theorem. Tactics are used to expand the current goal (the one on the top of the goal stack) into subgoals and justifications. These are pushed onto the goal stack and justification stack, respectively, to form a new proof state. Several preceding proof states are saved and can be returned to if a mistake is made in the proof. The goal stack is divided into levels, a new level being created each time a tactic is successfully applied to give new subgoals. The subgoals of the current level may be considered in any order.

If a tactic solves the current goal (returns an empty subgoal list), then its justification is used to prove a corresponding theorem. This theorem is then incorporated into the justification of the parent goal. If the subgoal was the last subgoal of the level, the level is removed and the parent goal is proved using its (new) justification. This process is repeated until a level with unproven subgoals is reached. The next goal on the goal

394

stack then becomes the current goal. If all the subgoals are proved, the resulting proof state consists of the theorem proved by the justifications. This theorem may be accessed and saved.

Comments

A more sophisticated subgoal management package will be implemented in the future.

b, backup, backup_limit, e, expand, expandf, g, get_state, p, print_state, r,
rotate, save_top_thm, set_state, top_goal, top_thm.
```

set_base_rewrites

set_base_rewrites: rewrites -> unit

Synopsis

Allows the user to control the built-in database of simplifications used in rewriting.

Description Uses

See also base_rewrites, add_base_rewrites, empty_rewrites, add_rewrites.

set_known_constants

Parse.set_known_constants : string list -> unit

Synopsis

Specifies the list of names that should be parsed as constants.

Description

One of the final phases of parsing is the resolution of free names in putative terms as either variables, constants or overloaded constants. If such a free name is not overloaded, then the list of known constants is consulted to determine whether or not to treat it as a constant. If the name is not present in the list, then it will be treated as a free variable.

Failure

Never fails. If a name is specified in the list of constants that is not in fact a constant, a warning message is printed, and that name is ignored.

Example

```
- known_constants();
> val it =
    ["bool_case", "ARB", "TYPE_DEFINITION", "ONTO", "ONE_ONE", "COND",
     "LET", "?!", "~", "F", "\\/", "/\\", "!", "T", "?", "@",
     "==>", "="]
    : string list
- Term'p /\ q';
> val it = 'p / q : Term.term
- set_known_constants (Lib.subtract (known_constants()) ["/\\"]);
> val it = () : unit
- Term'p /\ q';
<<HOL message: inventing new type variable names: 'a, 'b, 'c.>>
> val it = 'p / q' : Term.term
- strip_comb it;
> val it = ('$/\', ['p', 'q']) : Term.term * Term.term list
- dest_var (#1 it);
> val it = ("/\\", ':'a -> 'b -> 'c') : string * Type.hol_type
```

Uses

When writing library code that calls the parser, it can be useful to know exactly what constants the parser will "recognise".

Comments

This function does not affect the contents of a theory. A constant made invisible using this call is still really present in the theory; it is just harder to find.

See also

hidden, hide, known_constants, reveal.

show_numeral_types

Globals.show_numeral_types : bool ref

Synopsis

A flag which causes numerals to be printed with suffix annotation when true.

Description

This flag controls the pretty-printing of numeral forms that have been added to the global grammar with the function add_numeral_form. If the flag is true, then all numeric values are printed with the single-letter suffixes that identify which type the value is.

Failure

Never fails, as it is just an SML value.

Example

```
- load "integerTheory";
> val it = () : unit
- Term'~3';
> val it = '~3' : Term.term
- show_numeral_types := true;
> val it = () : unit
- Term'~3';
> val it = '~3i' : Term.term
```

Uses

Can help to disambiguate terms involving numerals.

See also

add_numeral_form, show_types

show_types

Globals.show_types : bool ref

Synopsis

Flag controlling printing of HOL types (in terms).

Description

Normally HOL types in terms are not printed, since this makes terms hard to read. Type printing is enabled by show_types := true, and disabled by show_types := false. When printing of types is enabled, not all variables and constants are annotated with a type. The intention is to provide sufficient type information to remove any ambiguities without swamping the term with type information.

Failure

Never fails.

Example

```
- BOOL_CASES_AX;;
> val it = |- !t. (t = T) \/ (t = F) : Thm.thm
- show_types := true;
> val it = () : unit
- BOOL_CASES_AX;;
> val it = |- !(t :bool). (t = T) \/ (t = F) : Thm.thm
```

Comments

It is possible to construct an abstraction in which the bound variable has the same name but a different type to a variable in the body. In such a case the two variables are considered to be distinct. Without type information such a term can be very misleading, so it might be a good idea to provide type information for the free variable whether or not printing of types is enabled.

See also

print_term.

SIMPSET

Synopsis

Constructs ssdata values.

Description

The ssdata type is the way in which simplification components are packaged up and made available to the simplifier (though ssdata values must first be turned into simpsets, either by addition to an existing simpset, or with the mk_simpset function).

The big record type passed to SIMPSET as an argument has six fields. Here we describe each in turn.

The ac field is a list of "AC theorem" pairs. Each such pair is the pair of theorems starting that a given binary function is associative and commutative. The form of the associative theorem must be

|-x op (y op z) = (x op y) op z

and the commutative theorem (the second element of the pair) must be of the form

|-x op y = y op x

Note that neither theorem can have any universal quantification.

The congs field is a list of congruence theorems justifying the addition of theorems to simplification contexts. For example, the congruence theorem for implication is

 $|-(P = P') \implies (P' \implies (Q = Q')) \implies (P \implies Q = P' \implies Q')$

This theorem encodes a rewriting strategy. The consequent of the chain of implications is the form of term in question, where the appropriate components have been rewritten. Then, in left-to-right order, the various antecedents of the implication specify the rewriting strategy which gives rise to the consequent. In this example, P is first simplified to P' without any additional context, then, using P' as additional context, simplification of Q proceeds, producing Q'. Another example is a rule for conjunction:

 $|-(P \implies (Q = Q')) \implies (Q' \implies (P = P')) \implies ((P / Q) = (P' / Q'))$

Here P is assumed while Q is simplified to Q'. Then, Q' is assumed while P is simplified to P'. If a antecedent doesn't involve the relation in question (here, equality) then it is treated as a side-condition, and the simplifier will be recursively invoked to try and solve it.

The convs field is a list of conversions that the simplifier will apply. Each conversion added to an ssdata value is done so in a record consisting of four fields.

The conv field of this subsidiary record type includes the value of the conversion itself. When the simplifier applies the conversion it is actually passed two extra arguments (as the type indicates). The first is a solver function that can be used to recursively do side-condition solving, and the second is a stack of side-conditions that have been accumulated to date. Many conversions will typically ignore these arguments (as in the example below).

The key field of the subsidiary record type is an optional pattern, specifying the places where the conversion should be applied. If the value is NONE, then the conversion will be applied to all sub-terms. It is not known what the role of the list of terms is. However, if it is the list is left as [], the second component of the pair, the bare term is used as a pattern. The conversion will only be applied to sub-terms that match the pattern. The name and trace fields are only relevant to the debugging facilities of the simplifier.

The aprocs field of the record passed to SIMPSET is where decision procedures can be specified. The construction of values of type reducer will be described in other reference entries (some of which may not have been written yet).

The filter field of the record is an optional function, which, if present, is composed with the standard simplifier's function for generating rewrites from theorems, and replaces that function. The version of this present in bool_ss and its descendents will, for example, turn |-P / Q into |-P and |-Q, and |-~(t1 = t2) into |-(t1 = t2) = F and |-(t2 = t1) = F.

The rewrs field of the record is a list of rewrite theorems that are to be applied.

Failure

Never fails. Failure to provide theorems of just the right form may cause later application of simplification functions to fail, documentation to the contrary notwithstanding.

Example

Given a conversion MUL_CONV to calculate multiplications, the following illustrates how this can be added to a simpset:

```
- val ssd = SIMPSET {ac = [], congs = [],
                     convs = [{conv = K (K MUL_CONV),
                               key= SOME ([], Term'x * y'),
                               name = "MUL_CONV",
                               trace = 2],
                     dprocs = [], filter = NONE, rewrs = []};
> val ssd =
    SIMPSET{ac = [], congs = [],
            convs =
              [{conv = fn, key = SOME([], 'x * y'), name = "MUL_CONV",
                trace = 2}], dprocs = [], filter = NONE, rewrs = []}
    : ssdata
- SIMP_CONV bool_ss [] (Term'3 * 4');
> val it = |- 3 * 4 = 3 * 4 : thm
- SIMP_CONV (bool_ss ++ ssd) [] (Term'3 * 4');
> val it = |- 3 * 4 = 12 : thm
```

Given the theorems ADD_SYM and ADD_ASSOC from arithmeticTheory, we can construct a

normaliser for additive terms.

Comments

SIMPSET is not the right name for something that creates an ssdata value. We still know too little about how this code works.

See also

++, bool_ss, mk_simpset, rewrites, SIMP_CONV

SIMP_CONV

simpLib.SIMP_CONV : simpset -> thm list -> conv

Synopsis

Applies a simpset and a list of rewrite rules to simplify a term.

Description

SIMP_CONV is the fundamental engine of the HOL simplification library. It repeatedly applies the transformations bound up in the the provided simpset augmented with the given rewrite rules to a term, ultimately yielding a theorem equating the original term to another.

Values of the simpset type embody a suite of different transformations that might be applicable to given terms. These "transformational components" are rewrites, conversions, AC-rules, congruences, decision procedures and a filter, which is used to modify the way in which rewrite rules are added to the simpset. The exact types for these components, and the way they can be combined to create simpsets is given in the reference entry for SIMPSET.

Rewrite rules are used similarly to the way in they are used in the rewriting system (REWRITE_TAC et al.). These are equational theorems oriented to rewrite from left-hand-side to right-hand-side. Further, SIMP_CONV handles obvious problems. If a rewrite rule is of the general form $[\ldots] \mid -x = f x$, then it will be discarded, and a message is printed to this effect. On the other hand, if the right-hand-side is a permutation of the pattern on the left, as in $\mid -x + y = y + x$ and $\mid -x$ INSERT (y INSERT s) = y INSERT (x INSERT s), then such rules will only be applied if the term to which they are being applied is strictly reduced according to some term ordering.

Rewriting is done using a form of higher-order matching, and also uses conditional rewriting. This latter means that theorems of the form |-P ==> (x = y) can be used as rewrites. If a term matching x is found, the simplifier will attempt to satisfy the side-condition P. If it is able to do so, then the rewriting will be performed. In the process of attempting to rewrite P to true, further side conditions may be generated. The simplifier limits the size of the stack of side conditions to be solved (the reference variable Cond_rewr.stack_limit holds this limit), so this will not introduce an infinite loop.

Rewrite rules can always be added "on the fly" as all of the simplification functions take a thm list argument where these rules can be specified. If a set of rewrite rules is frequently used, then these should probably be made into a ssdata value with the rewrites function and then added to an existing simpset with ++.

The conversions which are part of simpsets are useful for situations where simple rewriting is not enough to transform certain terms. For example, the BETA_CONV conversion is not expressible as a standard first order rewrite, but is part of the bool_ss simpset and the application of this simpset will thus simplify all occurrences of (\x. e1) e2.

In fact, conversions in simpsets are not typically applied indiscriminately to all subterms. (If a conversion is applied to an inappropriate sub-term and fails, this failure is caught by the simplifier and ignored.) Instead, conversions in simpsets are accompanied by a term-pattern which specifies the sort of situations in which they should be applied. This facility is used in the definition of bool_ss to include ETA_CONV, but stop it from transforming !x. P x into \$! P. Similarly, if one had a conversion for deciding equalities over a certain type foo, one would add the relevant conversion keyed on terms ''x:foo = y''.

AC-rules allow simpsets to be constructed that automatically normalise terms involving associative and commutative operators, again according to some arbitrary term ordering metric.

Congruence rules allow SIMP_CONV to assume additional context as a term is rewritten. In a term such as P ==> Q /\ f x the truth of term P may be assumed as an additional piece of context in the rewriting of Q /\ f x. The congruence theorem that states this is valid is (Ho_theorems.IMP_CONG):

 $|-(P = P') \implies (P' \implies (Q = Q')) \implies ((P \implies Q) = (P' \implies Q'))$

Other congruence theorems can be part of simpsets. The system provides IMP_CONG above and COND_CONG as part of the CONG_ss ssdata value. (These ssdata values can be incorporated into simpsets with the ++ function.) Other congruence theorems are already proved for operators such as conjunction and disjunction, but use of these in standard simpsets is not recommended as the computation of all the additional contexts for a simple chain of conjuncts or disjuncts can be very computationally intensive.

Decision procedures in simpsets are similar to conversions. They are arbitrary pieces of code that are applied to sub-terms at low priority. They are given access to the wider context through a list of relevant theorems. The hol_ss simpset includes an arithmetic decision procedure implemented in this way.

Failure

SIMP_CONV never fails, but may diverge.

Example

- SIMP_CONV hol_ss [] ''(\x. x + 3) 4''; > val it = |- (\x. x + 3) 4 = 7 : thm

Uses

SIMP_CONV is a powerful way of manipulating terms. Other functions in the simplification library provide the same facilities when in the contexts of goals and tactics (SIMP_TAC, ASM_SIMP_TAC etc.), and theorems (SIMP_RULE), but SIMP_CONV provides the underlying functionality, and is useful in its own right, just as conversions are generally.

Comments

This documentation is incomplete, due to a lack of understanding on the author's part of another's code.

See also

++, ASM_SIMP_TAC, FULL_SIMP_TAC, hol_ss, mk_simpset, rewrites, SIMP_RULE, SIMP_TAC, SIMPSET

SIMP_PROVE

Synopsis

Like SIMP_CONV, but converts boolean terms to theorem with same conclusion.

Description

SIMP_PROVE ss thml is equivalent to EQT_ELIM o SIMP_CONV ss thml.

Failure

Fails if the term can not be shown to be equivalent to true. May diverge.

Example

Using SIMP_PROVE here allows ASSUME_TAC to add a new fact, where the equality with truth that SIMP_CONV would produce would be less useful.

Uses

SIMP_PROVE is useful when constructing theorems to be passed to other tools, where those other tools would prefer not to have theorems of the form |-P = T.

See also

SIMP_CONV, SIMP_RULE, SIMP_TAC.

SIMP_RULE

simpLib.SIMP_RULE : simpset -> thm list -> thm -> thm

Synopsis

Simplifies the conclusion of a theorem according to the given simpset and theorem rewrites.

Description

SIMP_RULE simplifies the conclusion of a theorem, adding the given theorems to the simpset parameter as rewrites. The way in which terms are transformed as a part of simplification is described in the entry for SIMP_CONV.

404

Failure

Never fails, but may diverge.

Example

The following also demonstrates the higher order rewriting possible with simplification (FORALL_AND_THM states |-(!x. P x / Q x) = (!x. P x) / (!x. Q x)):

Comments

SIMP_RULE ss thmlist is equivalent to CONV_RULE (SIMP_CONV ss thmlist).

See also

ASM_SIMP_RULE, SIMP_CONV, SIMP_TAC.

SIMP_TAC

simpLib.SIMP_TAC : simpset -> thm list -> tactic

Synopsis

Simplifies the goal, using the given simpset and the additional theorems listed.

Description

SIMP_TAC adds the theorems of the second argument to the simpset argument as rewrites and then applies the resulting simpset to the conclusion of the goal. The exact behaviour of a simpset when applied to a term is described further in the entry for SIMP_CONV.

With simple simpsets, SIMP_TAC is similar in effect to REWRITE_TAC; it transforms the conclusion of a goal by using the (equational) theorems given and those already in the simpset as rewrite rules over the structure of the conclusion of the goal.

Just as ASM_REWRITE_TAC includes the assumptions of a goal in the rewrite rules that REWRITE_TAC uses, ASM_SIMP_TAC adds the assumptions of a goal to the rewrites and then performs simplification.

Failure

SIMP_TAC never fails, though it may diverge.

Example

SIMP_TAC and the hol_ss simpset combine to prove quite difficult seeming goals:

```
- val (_, p) =
    SIMP_TAC hol_ss [] ([], Term'P x /\ (x = y + 3) ==> P x /\ y < x');
> val p = fn : thm list -> thm
- p [];
> val it = |- P x /\ (x = y + 3) ==> P x /\ y < x : thm</pre>
```

SIMP_TAC is similar to REWRITE_TAC if used with just the bool_ss simpset. Here it is used in conjunction with the arithmetic theorem GREATER_DEF, |- |m n. m > n = n < m, to advance a goal:

```
- SIMP_TAC bool_ss [GREATER_DEF] ([], Term'T /\ 5 > 4 \/ F');
> val it = ([([], '4 < 5')], fn) : subgoals</pre>
```

Comments

The simplification library is described further in other documentation, but its full capabilities are still rather opaque.

Uses

Simplification is one of the most powerful tactics available to the HOL user. It can be used both to solve goals entirely or to make progress with them. However, poor simpsets or a poor choice of rewrites can still result in divergence, or poor performance.

See also

```
++, ASM_SIMP_TAC, bool_ss, FULL_SIMP_TAC, hol_ss, mk_simpset, REWRITE_TAC, SIMP_CONV, SIMP_PROVE, SIMP_RULE.
```

SKOLEM_CONV

SKOLEM_CONV : conv

Synopsis

Proves the existence of a Skolem function.

Description

When applied to an argument of the form !x1...xn. ?y. P, the conversion SKOLEM_CONV returns the theorem:

|- (!x1...xn. ?y. P) = (?y'. !x1...xn. P[y' x1 ... xn/y])

where y' is a primed variant of y not free in the input term.

Failure

SKOLEM_CONV tm fails if tm is not a term of the form !x1...xn. ?y. P.

See also

X_SKOLEM_CONV.

snd

snd : ((* # **) -> **)

Synopsis

Extracts the second component of a pair.

Description snd (x,y) returns y.

Failure Never fails.

See also fst, pair.

sort

sort : (((* # *) -> bool) -> * list -> * list)

Synopsis

Sorts a list using a given transitive 'ordering' relation.

Description

The call

sort op list

where op is an (uncurried) transitive relation on the elements of list, will topologically sort the list, i.e. will permute it such that if x op y but not y op x then x will occur to the left of y in the sorted list. In particular if op is a total order, the list will be sorted in the usual sense of the word.

snd

Failure

Never fails.

Example

A simple example is:

#sort \$< [3; 1; 4; 1; 5; 9; 2; 6; 5; 3; 5; 8; 9; 7; 9];;
[1; 1; 2; 3; 3; 4; 5; 5; 5; 6; 7; 8; 9; 9; 9] : int list</pre>

The following example is a little more complicated. Note that the 'ordering' is not antisymmetric.

```
#sort ($< o (fst # fst)) [(1,3); (7,11); (3,2); (3,4); (7,2); (5,1)];;
[(1, 3); (3, 4); (3, 2); (5, 1); (7, 2); (7, 11)] : (int # int) list
```

SPEC

SPEC : (term \rightarrow thm \rightarrow thm)

Synopsis

Specializes the conclusion of a theorem.

Description

When applied to a term u and a theorem $A \mid - !x$. t, then SPEC returns the theorem $A \mid - t[u/x]$. If necessary, variables will be renamed prior to the specialization to ensure that u is free for x in t, that is, no variables free in u become bound after substitution.

```
A |- !x. t
----- SPEC "u"
A |- t[u/x]
```

Failure

Fails if the theorem's conclusion is not universally quantified, or if x and u have different types.

Example

The following example shows how SPEC renames bound variables if necessary, prior to substitution: a straightforward substitution would result in the clearly invalid theorem

```
|- ~y ==> (!y. y ==> ~y).
#let xv = "x:bool" and yv="y:bool" in
# (GEN xv o DISCH xv o GEN yv o DISCH yv) (ASSUME xv);;
|- !x. x ==> (!y. y ==> x)
#SPEC "~y" it;;
|- ~y ==> (!y'. y' ==> ~y)
```

See also

ISPEC, SPECL, SPEC_ALL, SPEC_VAR, GEN, GENL, GEN_ALL.

SPECL

SPECL : (term list -> thm -> thm)

Synopsis

Specializes zero or more variables in the conclusion of a theorem.

Description

When applied to a term list [u1; ...; un] and a theorem A |-!x1...xn. t, the inference rule SPECL returns the theorem A |-t[u1/x1]...[un/xn], where the substitutions are made sequentially left-to-right in the same way as for SPEC, with the same sort of alpha-conversions applied to t if necessary to ensure that no variables which are free in ui become bound after substitution.

A |- !x1...xn. t ----- SPECL "[u1;...;un]" A |- t[u1/x1]...[un/xn]

It is permissible for the term-list to be empty, in which case the application of SPECL has no effect.

Failure

Fails unless each of the terms is of the same as that of the appropriate quantified variable in the original theorem.

Example

The following is a specialization of a theorem from theory arithmetic.

#let t = theorem 'arithmetic' 'LESS_EQ_LESS_EQ_MONO';; t = |- !m n p q. m <= p /\ n <= q ==> (m + n) <= (p + q) #SPECL ["1"; "2"; "3"; "4"] t;; |- 1 <= 3 /\ 2 <= 4 ==> (1 + 2) <= (3 + 4)</pre>

See also

GEN, GENL, GEN_ALL, GEN_TAC, SPEC, SPEC_ALL, SPEC_TAC.

SPEC_ALL

SPEC_ALL : (thm -> thm)

Synopsis

Specializes the conclusion of a theorem with its own quantified variables.

Description

When applied to a theorem $A \mid - !x1...xn$. t, the inference rule SPEC_ALL returns the theorem $A \mid - t[x1'/x1]...[xn'/xn]$ where the xi' are distinct variants of the corresponding xi, chosen to avoid clashes with any variables free in the assumption list and with the names of constants. Normally xi' is just xi, in which case SPEC_ALL simply removes all universal quantifiers.

A |- !x1...xn. t ----- SPEC_ALL A |- t[x1'/x1]...[xn'/xn]

Failure

Never fails.

Example

The following example shows how variables are also renamed to avoid clashing with

410

the names of constants.

#let v=mk_var('T',":bool") in ASSUME "!^v. ^v \/ ~^v";; !T. T \/ ~T |- !T. T \/ ~T #SPEC_ALL it;; !T. T \/ ~T |- T' \/ ~T'

See also

GEN, GENL, GEN_ALL, GEN_TAC, SPEC, SPECL, SPEC_ALL, SPEC_TAC.

SPEC_TAC

SPEC_TAC : ((term # term) -> tactic)

Synopsis

Generalizes a goal.

Description

When applied to a pair of terms (u,x), where x is just a variable, and a goal A ?- t, the tactic SPEC_TAC generalizes the goal to A ?- !x. t[x/u], that is, all instances of u are turned into x.

```
A ?- t
========== SPEC_TAC ("u","x")
A ?- !x. t[x/u]
```

Failure

Fails unless x is a variable with the same type as u.

Uses

Removing unnecessary speciality in a goal, particularly as a prelude to an inductive proof.

See also

GEN, GENL, GEN_ALL, GEN_TAC, SPEC, SPECL, SPEC_ALL, STRIP_TAC.

SPEC_VAR

```
SPEC_VAR : (thm -> (term # thm))
```

Synopsis

Specializes the conclusion of a theorem, returning the chosen variant.

Description

When applied to a theorem $A \mid - !x$. t, the inference rule SPEC_VAR returns the term x' and the theorem $A \mid -t[x'/x]$, where x' is a variant of x chosen to avoid free variable capture.

A |- !x. t ----- SPEC_VAR A |- t[x'/x]

Failure

Fails unless the theorem's conclusion is universally quantified.

Comments

This rule is very similar to plain SPEC, except that it returns the variant chosen, which may be useful information under some circumstances.

See also

GEN, GENL, GEN_ALL, GEN_TAC, SPEC, SPECL, SPEC_ALL.

split

split : ('a * 'b) list -> ('a list * 'b list)

Synopsis

Converts a list of pairs into a pair of lists.

Description

split [(x1,y1),...,(xn,yn)] returns ([x1,...,xn],[y1,...,yn]).

Failure

Never fails.

Comments

Identical to the Basis function ListPair.unzip.

See also

combine.

string_of_int

Compat.string_of_int : int -> string

Synopsis

Maps an integer to the corresponding decimal string.

Description

Found in the hol88 library. When given an integer, string_of_int returns a string representing the number in standard decimal notation, with a leading minus sign if the number is negative, and no leading zeros.

Failure

Never fails. The function is not available unless the hol88 library has been loaded.

Comments

Not found in hol90, since the author always got it backwards; use int_to_string instead. Likewise, int_of_string is not found in hol90; use string_to_int.

See also

ascii, ascii_code, int_of_string, int_to_string, string_to_int.

strip_abs

strip_abs : (term -> goal)

Synopsis

Iteratively breaks apart abstractions.

Description

strip_abs "\x1 ... xn. t" returns (["x1";...;"xn"],"t"). Note that

strip_abs(list_mk_abs(["x1";...;"xn"],"t"))

will not return (["x1";...;"xn"],"t") if t is an abstraction.

Failure

Never fails.

See also

list_mk_abs, dest_abs.

STRIP_ASSUME_TAC

STRIP_ASSUME_TAC : thm_tactic

Synopsis

Splits a theorem into a list of theorems and then adds them to the assumptions.

Description

Given a theorem th and a goal (A,t), STRIP_ASSUME_TAC th splits th into a list of theorems. This is done by recursively breaking conjunctions into separate conjuncts, casessplitting disjunctions, and eliminating existential quantifiers by choosing arbitrary variables. Schematically, the following rules are applied:

where x, is a variant of x.

If the conclusion of th is not a conjunction, a disjunction or an existentially quantified term, the whole theorem th is added to the assumptions.

414

As assumptions are generated, they are examined to see if they solve the goal (either by being alpha-equivalent to the conclusion of the goal or by deriving a contradiction).

The assumptions of the theorem being split are not added to the assumptions of the goal(s), but they are recorded in the proof. This means that if A' is not a subset of the assumptions A of the goal (up to alpha-conversion), STRIP_ASSUME_TAC (A'|-v) results in an invalid tactic.

Failure

Never fails.

Example

When solving the goal

?-m = 0 + m

assuming the clauses for addition with STRIP_ASSUME_TAC ADD_CLAUSES results in the goal

{m + (SUC n) = SUC(m + n), (SUC m) + n = SUC(m + n), m + 0 = m, 0 + m = m, m = 0 + m} ?- m = 0 + m

while the same tactic directly solves the goal

?-0 + m = m

Uses

STRIP_ASSUME_TAC is used when applying a previously proved theorem to solve a goal, or when enriching its assumptions so that resolution, rewriting with assumptions and other operations involving assumptions have more to work with.

See also

ASSUME_TAC, CHOOSE_TAC, CHOOSE_THEN, CONJUNCTS_THEN, DISJ_CASES_TAC, DISJ_CASES_THEN.

strip_comb

strip_comb : (term -> (term # term list))

Synopsis

Iteratively breaks apart combinations (function applications).

Description

strip_comb "t t1 ... tn" returns ("t", ["t1"; ...; "tn"]). Note that

```
strip_comb(list_mk_comb("t",["t1";...;"tn"]))
```

will not return ("t", ["t1"; ...; "tn"]) if t is a combination.

Failure

Never fails.

Example

```
#strip_comb "x /\ y";;
("$/\", ["x"; "y"]) : (term # term list)
```

```
#strip_comb "T";;
("T", []) : (term # term list)
```

See also

list_mk_comb, dest_comb.

strip_exists

```
strip_exists : (term -> goal)
```

Synopsis

Iteratively breaks apart existential quantifications.

Description

strip_exists "?x1 ... xn. t" returns (["x1";...;"xn"],"t"). Note that

```
strip_exists(list_mk_exists(["x1";...;"xn"],"t"))
```

will not return (["x1";...;"xn"],"t") if t is an existential quantification.

Failure

Never fails.

See also

list_mk_exists, dest_exists.

416

strip_forall

```
strip_forall : (term -> goal)
```

Synopsis

Iteratively breaks apart universal quantifications.

Description

strip_forall "!x1 ... xn. t" returns (["x1";...;"xn"],"t"). Note that

```
strip_forall(list_mk_forall(["x1";...;"xn"],"t"))
```

will not return (["x1";...;"xn"],"t") if t is a universal quantification.

Failure

Never fails.

See also

list_mk_forall, dest_forall.

STRIP_GOAL_THEN

STRIP_GOAL_THEN : (thm_tactic -> tactic)

Synopsis

Splits a goal by eliminating one outermost connective, applying the given theorem-tactic to the antecedents of implications.

Description

Given a theorem-tactic ttac and a goal (A,t), STRIP_GOAL_THEN removes one outermost occurrence of one of the connectives !, ==>, ~ or /\ from the conclusion of the goal t. If t is a universally quantified term, then STRIP_GOAL_THEN strips off the quantifier:

```
A ?- !x.u
========== STRIP_GOAL_THEN ttac
A ?- u[x'/x]
```

where x' is a primed variant that does not appear free in the assumptions A. If t is a

conjunction, then STRIP_GOAL_THEN simply splits the conjunction into two subgoals:

A ?- v /\ w =========== STRIP_GOAL_THEN ttac A ?- v A ?- w

If t is an implication "u = v" and if:

then:

A ?- u ==> v ============ STRIP_GOAL_THEN ttac A' ?- v'

Finally, a negation \tilde{t} is treated as the implication t ==> F.

Failure

STRIP_GOAL_THEN ttac (A,t) fails if t is not a universally quantified term, an implication, a negation or a conjunction. Failure also occurs if the application of ttac fails, after stripping the goal.

Example

When solving the goal

?- (n = 1) => (n * n = n)

a possible initial step is to apply

STRIP_GOAL_THEN SUBST1_TAC

thus obtaining the goal

?-1 * 1 = 1

Uses

STRIP_GOAL_THEN is used when manipulating intermediate results (obtained by stripping outer connectives from a goal) directly, rather than as assumptions.

See also

CONJ_TAC, DISCH_THEN, FILTER_STRIP_THEN, GEN_TAC, STRIP_ASSUME_TAC, STRIP_TAC.

strip_imp

```
strip_imp : (term -> goal)
```

Synopsis

Iteratively breaks apart implications.

Description

```
strip_imp "t1 ==> ( ... (tn ==> t)...)" returns (["t1";...;"tn"],"t"). Note that
```

```
strip_imp(list_mk_imp(["t1";...;"tn"],"t"))
```

will not return (["t1";...;"tn"],"t") if t is an implication.

Failure

Never fails.

Example

#strip_imp "(T ==> F) ==> (T ==> F)";; (["T ==> F"; "T"], "F") : goal

See also

list_mk_imp, dest_imp.

strip_pair

strip_pair : (term -> term list)

Synopsis

Iteratively breaks apart tuples.

Description

strip_pair("(t1,...,tn)") returns ["t1";...;"tn"]. A term that is not a tuple is simply
returned as the sole element of a list. Note that

strip_pair(list_mk_pair ["t1";...;"tn"])

will not return ["t1";...;"tn"] if tn is a pair or a tuple.

Failure

Never fails.

Example

```
#list_mk_pair ["(1,2)";"(3,4)";"(5,6)"];;
"(1,2),(3,4),5,6" : term
```

```
#strip_pair it;;
["1,2"; "3,4"; "5"; "6"] : term list
```

```
#strip_pair "1";;
["1"] : term list
```

See also

```
list_mk_pair, dest_pair.
```

STRIP_TAC

STRIP_TAC : tactic

Synopsis

Splits a goal by eliminating one outermost connective.

Description

Given a goal (A,t), STRIP_TAC removes one outermost occurrence of one of the connectives $!, ==>, \sim$ or /\ from the conclusion of the goal t. If t is a universally quantified term, then STRIP_TAC strips off the quantifier:

A ?- !x.u ========= STRIP_TAC A ?- u[x'/x]

where x' is a primed variant that does not appear free in the assumptions A. If t is a conjunction, then STRIP_TAC simply splits the conjunction into two subgoals:

A ?- v /\ w =========== STRIP_TAC A ?- v A ?- w

If t is an implication, STRIP_TAC moves the antecedent into the assumptions, stripping

420

conjunctions, disjunctions and existential quantifiers according to the following rules:

A ?- v1 /\ ... /\ vn ==> v A u {v1,...,vn} ?- v A ?- ?x.w ==> v A u {w[x'/x]} ?- v

where x' is a primed variant of x that does not appear free in A. Finally, a negation t is treated as the implication t ==> F.

Failure

STRIP_TAC (A,t) fails if t is not a universally quantified term, an implication, a negation or a conjunction.

Example

Applying STRIP_TAC twice to the goal:

?- !n. m <= n /\ n <= m ==> (m = n)

results in the subgoal:

 ${n <= m, m <= n} ?- m = n$

Uses

When trying to solve a goal, often the best thing to do first is REPEAT STRIP_TAC to split the goal up into manageable pieces.

See also

CONJ_TAC, DISCH_TAC, DISCH_THEN, GEN_TAC, STRIP_ASSUME_TAC, STRIP_GOAL_THEN.

STRIP_THM_THEN

STRIP_THM_THEN : thm_tactical

Synopsis

STRIP_THM_THEN applies the given theorem-tactic using the result of stripping off one outer connective from the given theorem.

Description

Given a theorem-tactic ttac, a theorem th whose conclusion is a conjunction, a disjunction or an existentially quantified term, and a goal (A,t), STRIP_THM_THEN ttac th first strips apart the conclusion of th, next applies ttac to the theorem(s) resulting from the stripping and then applies the resulting tactic to the goal.

In particular, when stripping a conjunctive theorem A' |- u /\ v, the tactic

ttac(u|-u) THEN ttac(v|-v)

resulting from applying ttac to the conjuncts, is applied to the goal. When stripping a disjunctive theorem $A' \mid - u \setminus / v$, the tactics resulting from applying ttac to the disjuncts, are applied to split the goal into two cases. That is, if

 A ?- t
 A ?- t

 ========
 ttac (u|-u) and ========
 ttac (v|-v)

 A ?- t1
 A ?- t2

then:

When stripping an existentially quantified theorem $A' \mid -?x.u$, the tactic ttac(u|-u), resulting from applying ttac to the body of the existential quantification, is applied to the goal. That is, if:

```
A ?- t
========= ttac (u|-u)
A ?- t1
```

then:

```
A ?- t
========== STRIP_THM_THEN ttac (A'|- ?x. u)
A ?- t1
```

The assumptions of the theorem being split are not added to the assumptions of the goal(s) but are recorded in the proof. If A' is not a subset of the assumptions A of the goal (up to alpha-conversion), STRIP_THM_THEN ttac th results in an invalid tactic.

Failure

STRIP_THM_THEN ttac th fails if the conclusion of th is not a conjunction, a disjunction or an existentially quantified term. Failure also occurs if the application of ttac fails, after stripping the outer connective from the conclusion of th.

Uses

STRIP_THM_THEN is used enrich the assumptions of a goal with a stripped version of a previously-proved theorem.

See also

CHOOSE_THEN, CONJUNCTS_THEN, DISJ_CASES_THEN, STRIP_ASSUME_TAC.

STRUCT_CASES_TAC

STRUCT_CASES_TAC : thm_tactic

Synopsis

Performs very general structural case analysis.

Description

When it is applied to a theorem of the form:

th = A' |- ?y11...y1m. (x=t1) /\ (B11 /\ ... /\ B1k) \/ ... \/ ?yn1...ynp. (x=tn) /\ (Bn1 /\ ... /\ Bnp)

in which there may be no existential quantifiers where a 'vector' of them is shown above, STRUCT_CASES_TAC th splits a goal A ?- s into n subgoals as follows:

that is, performs a case split over the possible constructions (the ti) of a term, providing as assumptions the given constraints, having split conjoined constraints into separate assumptions. Note that unless A' is a subset of A, this is an invalid tactic.

Failure

Fails unless the theorem has the above form, namely a conjunction of (possibly multiply existentially quantified) terms which assert the equality of the same variable x and the given terms.

Example

Suppose we have the goal:

?- ~(l:(*)list = []) ==> (LENGTH 1) > 0

then we can get rid of the universal quantifier from the inbuilt list theorem list_CASES:

list_CASES = !1. (1 = []) \/ (?t h. 1 = CONS h t)

and then use STRUCT_CASES_TAC. This amounts to applying the following tactic:

STRUCT_CASES_TAC (SPEC_ALL list_CASES)

which results in the following two subgoals:

?- ~(CONS h t = []) ==> (LENGTH(CONS h t)) > 0
?- ~([] = []) ==> (LENGTH[]) > 0

Note that this is a rather simple case, since there are no constraints, and therefore the resulting subgoals have no assumptions.

Uses

Generating a case split from the axioms specifying a structure.

See also

ASM_CASES_TAC, BOOL_CASES_TAC, COND_CASES_TAC, DISJ_CASES_TAC.

SUBGOAL_THEN

SUBGOAL_THEN : (term -> thm_tactic -> tactic)

Synopsis

Allows the user to introduce a lemma.

Description

The user proposes a lemma and is then invited to prove it under the current assump-

tions. The lemma is then used with the thm_tactic to simplify the goal. That is, if

```
A1 ?- t1
======== f (u |- u)
A2 ?- t2
```

then

```
A1 ?- t1
================= SUBGOAL_THEN "u" f
A1 ?- u A2 ?- t2
```

Failure

SUBGOAL_THEN will fail with 'ASSUME' if an attempt is made to use a nonboolean term as a lemma.

Uses

When combined with rotate, SUBGOAL_THEN allows the user to defer some part of a proof and to continue with another part. SUBGOAL_THEN is most convenient when the tactic solves the original goal, leaving only the subgoal. For example, suppose the user wishes top prove the goal

 ${n = SUC m} ?- (0 = n) => t$

Using SUBGOAL_THEN to focus on the case in which (n = 0), rewriting establishes it truth, leaving only the proof that (n = 0). That is,

```
SUBGOAL_THEN "~(0 = n)" (\th:thm. REWRITE_TAC [th])
```

generates the following subgoals:

 ${n = SUC m} ?- ~(0 = n)$?- T

Comments

Some users may expect the generated tactic to be f (A1 |-u), rather than f (u |-u).

SUBS

SUBS : (thm list -> thm -> thm)

Synopsis

Makes simple term substitutions in a theorem using a given list of theorems.

Description

Term substitution in HOL is performed by replacing free subterms according to the transformations specified by a list of equational theorems. Given a list of theorems A1|-t1=v1,...,An|-tn=vn and a theorem A|-t, SUBS simultaneously replaces each free occurrence of ti in t with vi:

A1|-t1=v1 ... An|-tn=vn A|-t ------ SUBS[A1|-t1=v1;...;An|-tn=vn] A1 u ... u An u A |- t[v1,...,vn/t1,...,tn] (A|-t)

No matching is involved; the occurrence of each ti being substituted for must be a free in t (see SUBST_MATCH). An occurrence which is not free can be substituted by using rewriting rules such as REWRITE_RULE, PURE_REWRITE_RULE and ONCE_REWRITE_RULE.

Failure

SUBS [th1;...;thn] (A|-t) fails if the conclusion of each theorem in the list is not an equation. No change is made to the theorem A |-t| if no occurrence of any left-hand side of the supplied equations appears in t.

Example

Substitutions are made with the theorems

```
#let thm1 = SPECL ["m:num"; "n:num"] ADD_SYM
#and thm2 = CONJUNCT1 ADD_CLAUSES;;
thm1 = |- m + n = n + m
thm2 = |- 0 + m = m
```

depending on the occurrence of free subterms

#SUBS [thm1; thm2] (ASSUME "(n + 0) + (0 + m) = m + n");; . |- (n + 0) + m = n + m #SUBS [thm1; thm2] (ASSUME "!n. (n + 0) + (0 + m) = m + n");; . |- !n. (n + 0) + m = m + n

Uses

SUBS can sometimes be used when rewriting (for example, with REWRITE_RULE) would diverge and term instantiation is not needed. Moreover, applying the substitution rules is often much faster than using the rewriting rules.

426

See also

ONCE_REWRITE_RULE, PURE_REWRITE_RULE, REWRITE_RULE, SUBST, SUBST_MATCH, SUBS_OCCS.

subst

subst : (term,term) subst -> term -> term

Synopsis

Substitutes terms in a term.

Description

Given a "(term,term) subst" (a list of redex, residue records) and a term tm, subst attempts to substitute each free occurrence of a redex in tm by its associated residue. The substitution is done in parallel, i.e., once a redex has been replaced by its residue, at some place in the term, that residue at that place will not itself be replaced in the current call. When necessary, renaming of bound variables in tm is done to avoid capturing the free variables of an incoming residue.

Failure

Failure occurs if there exists a redex, residue record in the substitution such that the types of the redex and residue are not equal.

Example

```
- load "arithmeticTheory";
- subst [''SUC 0'' |-> ''1''] ''SUC(SUC 0)'';
> val it = ''SUC 1'' : term
- subst [''SUC 0'' |-> ''1'', ''SUC 1'' |-> ''2''] ''SUC(SUC 0)'';
> val it = ''SUC 1'' : term
- subst [''SUC(SUC 0) = SUC 1'';
> val it = ''SUC 1 = 2'' : term
- subst [''b:num'' |-> ''a:num''] ''\a:num. (b:num)'';
> val it = ''\a'. a'' : term
- subst[''flip:'a'' |-> ''foo:'a''] ''waddle:'a''
> val it = ''waddle'' : term
```

SUBST

SUBST : (term, thm) subst -> term -> thm -> thm

Synopsis

Makes a set of parallel substitutions in a theorem.

Description

Implements the following rule of simultaneous substitution

A1 |- t1 = u1 , ... , An |- tn = un , A |- t[t1,...,tn] ------A u A1 u ... u An |- t[ui]

Evaluating

```
SUBST [x1 |-> (A1 |- t1=u1) ,..., xn |-> (An |- tn=un)]
t[x1,...,xn]
(A |- t[t1,...,tn])
```

returns the theorem A1 u ... An |-t[u1,...,un]. The term argument t[x1,...,xn] is a template which should match the conclusion of the theorem being substituted into, with the variables x1, ..., xn marking those places where occurrences of t1, ..., tn are to be replaced by the terms u1, ..., un, respectively. The occurrence of ti at the places marked by xi must be free (i.e. ti must not contain any bound variables). SUBST automatically renames bound variables to prevent free variables in ui becoming bound after substitution.

SUBST is a complex primitive because it performs both parallel simultaneous substitution and renaming of variables. This is for efficiency reasons, but it would be logically cleaner if SUBST were simpler.

Failure

If the template does not match the conclusion of the hypothesis, or the terms in the conclusion marked by the variables $x_1, ..., x_n$ in the template are not identical to the left hand sides of the supplied equations (i.e. the terms $t_1, ..., t_n$).

Example

```
- val x = --'x:num'--
   and y = --'y:num'--
   and th0 = SPEC (--'0'--) arithmeticTheory.ADD1
   and th1 = SPEC (--'1'--) arithmeticTheory.ADD1;
(* x = (--'x'--)
     y = (--'y' - -)
   th0 = |-SUC 0 = 0 + 1
   th1 = |-SUC 1 = 1 + 1
                              *)
 - SUBST [x |-> th0, y |-> th1] (-- '(x+y) > SUC 0'--)
        (ASSUME (--'(SUC 0 + SUC 1) > SUC 0'--));
 val it = [.] |- (0 + 1) + 1 + 1 > SUC 0 : thm
 - SUBST [x |-> th0, y |-> th1] (--'(SUC 0 + y) > SUC 0'--)
         (ASSUME (--'(SUC 0 + SUC 1) > SUC 0'--));
 val it = [.] |- SUC 0 + 1 + 1 > SUC 0 : thm
 - SUBST [x |-> th0, y |-> th1] (--'(x+y) > x'--)
         (ASSUME (--'(SUC 0 + SUC 1) > SUC 0'--));
 val it = [.] |- (0 + 1) + 1 + 1 > 0 + 1 : thm
```

Uses

For substituting at selected occurrences. Often useful for writing special purpose derived inference rules.

See also

SUBS.

SUBST1_TAC

SUBST1_TAC : thm_tactic

Synopsis

Makes a simple term substitution in a goal using a single equational theorem.

Description

Given a theorem A'|-u=v and a goal (A,t), the tactic SUBST1_TAC (A'|-u=v) rewrites the term t into t[v/u], by substituting v for each free occurrence of u in t:

A ?- t =========== SUBST1_TAC (A'|-u=v) A ?- t[v/u]

The assumptions of the theorem used to substitute with are not added to the assumptions of the goal but are recorded in the proof. If A' is not a subset of the assumptions A of the goal (up to alpha-conversion), then $SUBST1_TAC$ (A'|-u=v) results in an invalid tactic.

SUBST1_TAC automatically renames bound variables to prevent free variables in v becoming bound after substitution.

Failure

SUBST1_TAC th (A,t) fails if the conclusion of th is not an equation. No change is made to the goal if no free occurrence of the left-hand side of th appears in t.

Example

When trying to solve the goal

?-m*n = (n*(m-1)) + n

substituting with the commutative law for multiplication

```
SUBST1_TAC (SPECL ["m:num"; "n:num"] MULT_SYM)
```

results in the goal

?-n * m = (n * (m - 1)) + n

Uses

SUBST1_TAC is used when rewriting with a single theorem using tactics such as REWRITE_TAC is too expensive or would diverge. Applying SUBST1_TAC is also much faster than using rewriting tactics.

See also

ONCE_REWRITE_TAC, PURE_REWRITE_TAC, REWRITE_TAC, SUBST_ALL_TAC, SUBST_TAC.

SUBST_ALL_TAC

SUBST_ALL_TAC : thm_tactic

Synopsis

Substitutes using a single equation in both the assumptions and conclusion of a goal.

Description

SUBST_ALL_TAC breaches the style of natural deduction, where the assumptions are kept fixed. Given a theorem A|-u=v and a goal ([t1;...;tn], t), SUBST_ALL_TAC (A|-u=v) transforms the assumptions t1,...,tn and the term t into t1[v/u],...,tn[v/u] and t[v/u] respectively, by substituting v for each free occurrence of u in both the assumptions and the conclusion of the goal.

The assumptions of the theorem used to substitute with are not added to the assumptions of the goal, but they are recorded in the proof. If A is not a subset of the assumptions of the goal (up to alpha-conversion), then $SUBST_ALL_TAC$ (A|-u=v) results in an invalid tactic.

SUBST_ALL_TAC automatically renames bound variables to prevent free variables in v becoming bound after substitution.

Failure

SUBST_ALL_TAC th (A,t) fails if the conclusion of th is not an equation. No change is made to the goal if no occurrence of the left-hand side of th appears free in (A,t).

Example

Simplifying both the assumption and the term in the goal

 $\{0 + m = n\}$?- 0 + (0 + m) = n

by substituting with the theorem |-0 + m = m for addition

SUBST_ALL_TAC (CONJUNCT1 ADD_CLAUSES)

results in the goal

 $\{m = n\}$?- 0 + m = n

See also

ONCE_REWRITE_TAC, PURE_REWRITE_TAC, REWRITE_TAC, SUBST1_TAC, SUBST_TAC.

432

SUBST_CONV

SUBST_CONV : {var :term, thm :thm} list -> term -> conv

Synopsis

Makes substitutions in a term at selected occurrences of subterms, using a list of theorems.

Description

SUBST_CONV implements the following rule of simultaneous substitution

A1 |- t1 = v1 ... An |- tn = vn ------A1 u ... u An |- t[t1,...,tn/x1,...,xn] = t[v1,...,vn/x1,...,xn]

The first argument to SUBST_CONV is a list [$\{var=x1, thm = A1|-t1=v1\}, \ldots, \{var = xn, thm = An|-The second argument is a template term t[x1, ..., xn], in which the variables x1, ..., xn are used to mark those places where occurrences of t1, ..., tn are to be replaced with the terms v1, ..., vn, respectively. Thus, evaluating$

```
SUBST_CONV [{var = x1, thm = A1|-t1=v1},...,{var = xn, thm = An|-tn=vn}]
t[x1,...,xn]
t[t1,...,tn/x1,...,xn]
```

returns the theorem

A1 u ... u An |-t[t1,...,tn/x1,...,xn] = t[v1,...,vn/x1,...,xn]

The occurrence of ti at the places marked by the variable xi must be free (i.e. ti must not contain any bound variables). SUBST_CONV automatically renames bound variables to prevent free variables in vi becoming bound after substitution.

Failure

SUBST_CONV [{var=x1,thm=th1},...,{var=xn,thm=thn}] t[x1,...,xn] t' fails if the conclusion of any theorem thi in the list is not an equation; or if the template t[x1,...,xn] does not match the term t'; or if and term ti in t' marked by the variable xi in the template, is not identical to the left-hand side of the conclusion of the theorem thi.

Example

The values

```
- val thm0 = SPEC (--'0'--) ADD1
= and thm1 = SPEC (--'1'--) ADD1
= and x = --'x:num'-- and y = --'y:num'--;
thm0 = |- SUC 0 = 0 + 1
thm1 = |- SUC 1 = 1 + 1
val x = (--'(x :num)'--) : term
val y = (--'(y :num)'--) : term
```

can be used to substitute selected occurrences of the terms SUC 0 and SUC 1 $\,$

```
- SUBST_CONV [{var=x, thm=thm0}, {var=y,thm=thm1}]
= (--'(x + y) > SUC 1'--)
= (--'(SUC 0 + SUC 1) > SUC 1'--);
val it = |- SUC 0 + SUC 1 > SUC 1 = (0 + 1) + 1 + 1 > SUC 1 : thm
```

Uses

SUBST_CONV is used when substituting at selected occurrences of terms and using rewriting rules/conversions is too extensive.

See also

REWR_CONV, SUBS, SUBST, SUBS_OCCS.

SUBST_MATCH

SUBST_MATCH : (thm -> thm -> thm)

Synopsis

Substitutes in one theorem using another, equational, theorem.

Description

Given the theorems A|-u=v and A'|-t, SUBST_MATCH (A|-u=v) (A'|-t) searches for one free instance of u in t, according to a top-down left-to-right search strategy, and then substitutes the corresponding instance of v.

A |- u=v A' |- t ------ SUBST_MATCH (A|-u=v) (A'|-t) A u A' |- t[v/u]

SUBST_MATCH allows only a free instance of u to be substituted for in t. An instance

which contain bound variables can be substituted for by using rewriting rules such as REWRITE_RULE, PURE_REWRITE_RULE and ONCE_REWRITE_RULE.

Failure

SUBST_MATCH th1 th2 fails if the conclusion of the theorem th1 is not an equation. Moreover, SUBST_MATCH (A|-u=v) (A'|-t) fails if no instance of u occurs in t, since the matching algorithm fails. No change is made to the theorem (A'|-t) if instances of u occur in t, but they are not free (see SUBS).

Example

The commutative law for addition

#let thm1 = SPECL ["m:num"; "n:num"] ADD_SYM;; thm1 = |- m + n = n + m

is used to apply substitutions, depending on the occurrence of free instances

```
#SUBST_MATCH thm1 (ASSUME "(n + 1) + (m - 1) = m + n");;
. |- (m - 1) + (n + 1) = m + n
#SUBST_MATCH thm1 (ASSUME "!n. (n + 1) + (m - 1) = m + n");;
. |- !n. (n + 1) + (m - 1) = m + n
```

Uses

SUBST_MATCH is used when rewriting with the rules such as REWRITE_RULE, using a single theorem is too extensive or would diverge. Moreover, applying SUBST_MATCH can be much faster than using the rewriting rules.

See also

ONCE_REWRITE_RULE, PURE_REWRITE_RULE, REWRITE_RULE, SUBS, SUBST.

subst_occs

subst_occs : int list list -> term subst -> term -> term

Synopsis

Substitutes for particular occurrences of subterms of a given term.

Description

For each redex, residue in the second argument, there should be a corresponding integer list 1_i in the first argument that specifies which free occurrences of redex_i in the third argument should be substituted by residue_i.

Failure

Failure occurs if any substitution fails, or if the length of the first argument is not equal to the length of the substitution. In other words, every substitution pair should be accompanied by a list specifying when the substitution is applicable.

Example

See also

subst

SUBST_OCCS_TAC

SUBST_OCCS_TAC : ((int list # thm) list -> tactic)

Synopsis

Makes substitutions in a goal at specific occurrences of a term, using a list of theorems.

Description

Given a list (l1,A1|-t1=u1), ..., (ln,An|-tn=un) and a goal (A,t), SUBST_OCCS_TAC replaces each ti in t with ui, simultaneously, at the occurrences specified by the integers in the list li = [o1; ...; ok] for each theorem Ai|-ti=ui.

The assumptions of the theorems used to substitute with are not added to the assumptions A of the goal, but they are recorded in the proof. If any Ai is not a subset of A (up

to alpha-conversion), SUBST_OCCS_TAC [(l1,A1|-t1=u1);...;(ln,An|-tn=un)] results in an invalid tactic.

SUBST_OCCS_TAC automatically renames bound variables to prevent free variables in ui becoming bound after substitution.

Failure

SUBST_OCCS_TAC [(l1,th1);...;(ln,thn)] (A,t) fails if the conclusion of any theorem in the list is not an equation. No change is made to the goal if the supplied occurrences li of the left-hand side of the conclusion of thi do not appear in t.

Example

When trying to solve the goal

(m + n) + (n + m) = (m + n) + (m + n)

applying the commutative law for addition on the third occurrence of the subterm m + n

SUBST_OCCS_TAC [([3],SPECL ["m:num"; "n:num"] ADD_SYM)]

results in the goal

(m + n) + (n + m) = (m + n) + (n + m)

Uses

SUBST_OCCS_TAC is used when rewriting a goal at specific occurrences of a term, and rewriting tactics such as REWRITE_TAC, PURE_REWRITE_TAC, ONCE_REWRITE_TAC, SUBST_TAC, etc. are too extensive or would diverge.

See also

ONCE_REWRITE_TAC, PURE_REWRITE_TAC, REWRITE_TAC, SUBST1_TAC, SUBST_TAC.

SUBST_TAC

```
SUBST_TAC : (thm list -> tactic)
```

Synopsis

Makes term substitutions in a goal using a list of theorems.

Description

Given a list of theorems A1|-u1=v1,...,An|-un=vn and a goal (A,t), SUBST_TAC rewrites the term t into the term t[v1,...,vn/u1,...,un] by simultaneously substituting vi for each occurrence of ui in t with vi:

The assumptions of the theorems used to substitute with are not added to the assumptions A of the goal, while they are recorded in the proof. If any Ai is not a subset of A (up to alpha-conversion), then SUBST_TAC [A1|-u1=v1,...,An|-un=vn] results in an invalid tactic.

SUBST_TAC automatically renames bound variables to prevent free variables in vi becoming bound after substitution.

Failure

SUBST_TAC [th1,...,thn] (A,t) fails if the conclusion of any theorem in the list is not an equation. No change is made to the goal if no occurrence of the left-hand side of the conclusion of thi appears in t.

Example

When trying to solve the goal

(n + 0) + (0 + m) = m + n

by substituting with the theorems

#let thm1 = SPECL ["m:num"; "n:num"] ADD_SYM
#and thm2 = CONJUNCT1 ADD_CLAUSES;;
thm1 = |- m + n = n + m
thm2 = |- 0 + m = m

applying SUBST_TAC [thm1; thm2] results in the goal

(n + 0) + m = n + m

Uses

SUBST_TAC is used when rewriting (for example, with REWRITE_TAC) is extensive or would diverge. Substituting is also much faster than rewriting.

See also

ONCE_REWRITE_TAC, PURE_REWRITE_TAC, REWRITE_TAC, SUBST1_TAC, SUBST_ALL_TAC.

SUBS_OCCS

SUBS_OCCS : ((int list # thm) list -> thm -> thm)

Synopsis

Makes substitutions in a theorem at specific occurrences of a term, using a list of equational theorems.

Description

Given a list (l1,A1|-t1=v1), ..., (ln,An|-tn=vn) and a theorem (A|-t), SUBS_OCCS simultaneously replaces each ti in t with vi, at the occurrences specified by the integers in the list li = [o1; ...; ok] for each theorem Ai|-ti=vi.

```
(l1,A1|-t1=v1) ... (ln,An|-tn=vn) A|-t
------ SUBS_OCCS[(l1,A1|-t1=v1);...;
A1 u ... An u A |- t[v1,...,vn/t1,...,tn] (ln,An|-tn=vn)] (A|-t)
```

Failure

SUBS_OCCS [(l1,th1);...;(ln,thn)] (A|-t) fails if the conclusion of any theorem in the list is not an equation. No change is made to the theorem if the supplied occurrences li of the left-hand side of the conclusion of thi do not appear in t.

Example

The commutative law for addition

```
#let thm = SPECL ["m:num"; "n:num"] ADD_SYM;;
thm = |- m + n = n + m
```

can be used for substituting only the second occurrence of the subterm m + n

#SUBS_OCCS [([2],thm)] (ASSUME "(n + m) + (m + n) = (m + n) + (m + n)");; . |- (n + m) + (m + n) = (n + m) + (m + n)

Uses

SUBS_OCCS is used when rewriting at specific occurrences of a term, and rules such as REWRITE_RULE, PURE_REWRITE_RULE, ONCE_REWRITE_RULE, and SUBS are too extensive or would diverge.

See also

ONCE_REWRITE_RULE, PURE_REWRITE_RULE, REWRITE_RULE, SUBS, SUBST, SUBST_MATCH.

subtract

subtract : (* list -> * list -> * list)

Synopsis

Computes the set-theoretic difference of two 'sets'.

Description

subtract 11 12 returns a list consisting of those elements of 11 that do not appear in 12.

Failure

Never fails.

Example

```
#subtract [1;2;3] [3;5;4;1];;
[2] : int list
```

#subtract [1;2;4;1] [4;5];;
[1; 2; 1] : int list

See also

setify, set_equal, union, intersect.

SUB_CONV

SUB_CONV : (conv -> conv)

Synopsis

Applies a conversion to the top-level subterms of a term.

Description

For any conversion c, the function returned by SUB_CONV c is a conversion that applies c to all the top-level subterms of a term. If the conversion c maps t to |-t = t', then SUB_CONV c maps an abstraction "\x.t" to the theorem:

|-(x.t) = (x.t')

That is, $SUB_CONV \ c \ x.t$ applies c to the body of the abstraction $\x.t$. If c is a conversion that maps "t1" to the theorem |-t1 = t1' and "t2" to the theorem

|-t2 = t2', then the conversion SUB_CONV c maps an application "t1 t2" to the theorem:

|-(t1 t2) = (t1' t2')

That is, $SUB_CONV c "t1 t2"$ applies c to the both the operator t1 and the operand t2 of the application "t1 t2". Finally, for any conversion c, the function returned by $SUB_CONV c$ acts as the identity conversion on variables and constants. That is, if "t" is a variable or constant, then $SUB_CONV c "t"$ returns |-t = t.

Failure

SUB_CONV c tm fails if tm is an abstraction "\x.t" and the conversion c fails when applied to t, or if tm is an application "t1 t2" and the conversion c fails when applied to either t1 or t2. The function returned by SUB_CONV c may also fail if the ML function c:term->thm is not, in fact, a conversion (i.e. a function that maps a term t to a theorem |-t = t').

See also

ABS_CONV, RAND_CONV, RATOR_CONV.

SWAP_EXISTS_CONV

```
SWAP_EXISTS_CONV : conv
```

Synopsis

Interchanges the order of two existentially quantified variables.

Description

When applied to a term argument of the form ?x y. P, the conversion SWAP_EXISTS_CONV returns the theorem:

|-(?x y. P) = (?y x. P)

Failure

SWAP_EXISTS_CONV fails if applied to a term that is not of the form ?x y. P.

SYM

SYM : (thm \rightarrow thm)

Synopsis

Swaps left-hand and right-hand sides of an equation.

Description

When applied to a theorem A |-t1 = t2, the inference rule SYM returns A |-t2 = t1.

A |- t1 = t2 ----- SYM A |- t2 = t1

Failure

Fails unless the theorem is equational.

See also

GSYM, NOT_EQ_SYM, REFL.

SYM_CONV

SYM_CONV : conv

Synopsis

Interchanges the left and right-hand sides of an equation.

Description

When applied to an equational term t1 = t2, the conversion SYM_CONV returns the theorem:

|-(t1 = t2) = (t2 = t1)

Failure

Fails if applied to a term that is not an equation.

See also

SYM.

TAC_PROOF

TAC_PROOF : ((goal # tactic) -> thm)

442

Synopsis

Attempts to prove a goal using a given tactic.

Description

When applied to a goal-tactic pair (A ?- t,tac), the TAC_PROOF function attempts to prove the goal A ?- t, using the tactic tac. If it succeeds, it returns the theorem A' |-t corresponding to the goal, where the assumption list A' may be a proper superset of A unless the tactic is valid; there is no inbuilt validity checking.

Failure

Fails unless the goal has hypotheses and conclusions all of type bool, and the tactic can solve the goal.

See also

PROVE, prove_thm, VALID.

Term

Parse.Term : term quotation -> term

Synopsis

Parses a quotation into a term value

Description

The parsing process for terms divides into four distinct phases.

The first phase converts the quotation argument into a relatively simple parse tree datatype, with the following datatype definition (from Absyn):

```
datatype vstruct
    = VAQ of term
    | VIDENT of string
    | VPAIR of vstruct * vstruct
    | VTYPED of vstruct * pretype
datatype absyn
    = AQ of term
    | IDENT of string
    | APP of absyn * absyn
    | LAM of vstruct * absyn
    | TYPED of absyn * pretype
```

This phase of parsing is concerned with the treatment of the rawest syntax. It has no notion of whether or not a term corresponds to a constant or a variable, so all preterm leaves are ultimately either IDENTS or AQS (anti-quotations).

This first phase converts infixes, mixfixes and all the other categories of syntactic rule from the global grammar into simple structures built up using APP. For example, 'x op y' (where op is an infix) will turn into

APP(APP(IDENT "op", IDENT "x"), IDENT "y")

and 'tok1 x tok2 y' (where tok1 $_$ tok2 has been declared as a TruePrefix form for the term f) will turn into

```
APP(APP(IDENT "f", IDENT "x"), IDENT "y")
```

The special syntaxes for "let" and record expressions are also handled at this stage. For more details on how this is done see the reference entry for parse_preTerm, which function can be used in isolation to see what is done at this phase.

The second phase of parsing consists of the resolution of names, identifying what were just VARs as constants, overloaded constants or genuine variables. This phase also annotates all leaves of the data structure (given in the entry for preTerm) with type information.

The third phase of parsing works over the second pre-term datatype and does typechecking, though ignoring overloaded values. The datatype being operated over uses reference variables to allow for efficiency, and the type-checking is done "in place". If type-checking is successful, the resulting value has consistent type annotations.

The final phase of parsing resolves overloaded constants. The type-checking done to this point may completely determine which choice of overloaded constant is appropriate, but if not, the choice may still be completely determined by the interaction of the possible types for the overloaded possibilities.

Finally, depending on the value of the global flags guessing_tyvars and guessing_overloads, the parser will make choices about how to resolve any remaining ambiguities.

The parsing process is driven in most respects by the global grammar. This value can be inspected with the term_grammar function.

Failure

All over place, and for all sorts of reasons.

Uses

Turns strings into terms.

See also

```
parse_preTerm, preTerm, Type, overload_on, guessing_overloads, guessing_tyvars,
term_grammar.
```

term_grammar

Parse.term_grammar : unit -> term_grammar.grammar

Synopsis

Returns the current global term grammar.

Failure

Never fails.

Comments

There is a pretty-printer installed in the interactive system so that term grammar values are presented nicely. The global term grammar is passed as a parameter to the Term parsing function in the Parse structure, and also drives the installed term and theorem pretty-printers.

See also

parse_from_grammars, Term

term_lt

term_lt : term -> term -> unit

Synopsis

A total ordering function on terms.

Description

term_lt tells whether one term is less than another in the ordering.

Failure

Never fails.

Example

```
- term_lt (--'x.x = T'--) (--'3 + 4'--) val it = false : bool
```

Comments

If not (term_lt tm1 tm2) and not (term_lt tm2 tm1), then tm1 = tm2, although it is faster to directly test for equality. Ordering of terms may be useful in implementing search trees and the like.

See also

type_lt

term_to_string

Parse.term_to_string : term -> string

Synopsis

Converts a term to a string.

Description

Uses the global term grammar and pretty-printing flags to turn a term into a string. It assumes that the string should be broken up as if for display on a screen that is as wide as the value stored in the Globals.linewidth variable.

Failure

Should never fail.

See also

print_term

THEN

\$THEN : (tactic -> tactic -> tactic)

Synopsis

Applies two tactics in sequence.

Description

If T1 and T2 are tactics, T1 THEN T2 is a tactic which applies T1 to a goal, then applies the tactic T2 to all the subgoals generated. If T1 solves the goal then T2 is never applied.

Failure

The application of THEN to a pair of tactics never fails. The resulting tactic fails if T1 fails when applied to the goal, or if T2 does when applied to any of the resulting subgoals.

Comments

Although normally used to sequence tactics which generate a single subgoal, it is worth remembering that it is sometimes useful to apply the same tactic to multiple subgoals; sequences like the following:

EQ_TAC THENL [ASM_REWRITE_TAC[]; ASM_REWRITE_TAC[]]

can be replaced by the briefer:

EQ_TAC THEN ASM_REWRITE_TAC[]

See also

EVERY, ORELSE, THENL.

THENC

\$THENC : (conv -> conv -> conv)

Synopsis

Applies two conversions in sequence.

Description

If the conversion c1 returns |-t = t' when applied to a term "t", and c2 returns |-t' = t'' when applied to "t'", then the composite conversion (c1 THENC c2) "t" returns |-t = t''. That is, (c1 THENC c2) "t" has the effect of transforming the term "t" first with the conversion c1 and then with the conversion c2.

Failure

(c1 THENC c2) "t" fails if either the conversion c1 fails when applied to "t", or if c1 "t" succeeds and returns |-t = t' but c2 fails when applied to "t'". (c1 THENC c2) "t" may also fail if either of c1 or c2 is not, in fact, a conversion (i.e. a function that maps a term t to a theorem |-t = t').

See also

EVERY_CONV.

THENL

\$THENL : (tactic -> tactic list -> tactic)

Synopsis

Applies a list of tactics to the corresponding subgoals generated by a tactic.

Description

If $T,T1,\ldots,Tn$ are tactics, T THENL $[T1;\ldots;Tn]$ is a tactic which applies T to a goal, and if it does not fail, applies the tactics $T1,\ldots,Tn$ to the corresponding subgoals, unless T completely solves the goal.

Failure

The application of THENL to a tactic and tactic list never fails. The resulting tactic fails if T fails when applied to the goal, or if the goal list is not empty and its length is not the same as that of the tactic list, or finally if Ti fails when applied to the i'th subgoal generated by T.

Uses

Applying different tactics to different subgoals.

See also

EVERY, ORELSE, THEN.

THEN_TCL

```
$THEN_TCL : (thm_tactical -> thm_tactical -> thm_tactical)
```

Synopsis

Composes two theorem-tacticals.

Description

If ttl1 and ttl2 are two theorem-tacticals, ttl1 THEN_TCL ttl2 is a theorem-tactical which composes their effect; that is, if:

```
ttl1 ttac th1 = ttac th2
```

and

ttl2 ttac th2 = ttac th3

then

(ttl1 THEN_TCL ttl2) ttac th1 = ttac th3

Failure

The application of THEN_TCL to a pair of theorem-tacticals never fails.

448

See also

EVERY_TCL, FIRST_TCL, ORELSE_TCL.

thm_count

thm_count : (void -> int)

Synopsis

Returns the current value of the theorem counter.

Description

HOL maintains a counter which is incremented every time a primitive inference is performed (or an axiom or definition set up). A call to thm_count() returns the current value of this counter

Failure

Never fails.

See also set_thm_count, timer.

TOP_DEPTH_CONV

TOP_DEPTH_CONV : (conv -> conv)

Synopsis

Applies a conversion top-down to all subterms, retraversing changed ones.

Description

TOP_DEPTH_CONV c tm repeatedly applies the conversion c to all the subterms of the term tm, including the term tm itself. The supplied conversion c is applied to the subterms of tm in top-down order and is applied repeatedly (zero or more times, as is done by REPEATC) at each subterm until it fails. If a subterm t is changed (up to alpha-equivalence) by virtue of the application of c to its own subterms, then then the term into which t is transformed is retraversed by applying TOP_DEPTH_CONV c to it.

Failure

TOP_DEPTH_CONV c tm never fails but can diverge.

Comments

The implementation of this function uses failure to avoid rebuilding unchanged subterms. That is to say, during execution the failure string 'QCONV' may be generated and later trapped. The behaviour of the function is dependent on this use of failure. So, if the conversion given as argument happens to generate a failure with string 'QCONV', the operation of TOP_DEPTH_CONV will be unpredictable.

See also

DEPTH_CONV, ONCE_DEPTH_CONV, REDEPTH_CONV.

```
top_goal
```

```
top_goal : (void -> goal)
```

Synopsis

Returns the current goal of the subgoal package.

Description

The function top_goal is part of the subgoal package. It returns the top goal of the goal stack in the current proof state. For a description of the subgoal package, see set_goal.

Failure

A call to top_goal will fail if there are no unproven goals. This could be because no goal has been set using set_goal or because the last goal set has been completely proved.

Uses

Examining the proof state after a proof fails.

See also

```
b, backup, backup_limit, e, expand, expandf, g, get_state, p, print_state, r,
rotate, save_top_thm, set_goal, set_state, top_thm.
```

top_thm

top_thm : (void -> thm)

450

Synopsis

Returns the theorem just proved using the subgoal package.

Description

The function top_thm is part of the subgoal package. A proof state of the package consists of either goal and justification stacks if a proof is in progress or a theorem if a proof has just been completed. If the proof state consists of a theorem, top_thm returns that theorem. For a description of the subgoal package, see set_goal.

Failure

top_thm will fail if the proof state does not hold a theorem. This will be so either because no goal has been set or because a proof is in progress with unproven subgoals.

Uses

Accessing the result of an interactive proof session with the subgoal package.

See also

```
b, backup, backup_limit, e, expand, expandf, g, get_state, p, print_state, r,
rotate, save_top_thm, set_goal, set_state, top_goal.
```

trace

trace : string -> int -> unit

Synopsis

Sets a tracing variable to a new value.

Description

The trace function is used to set the value of a tracing variable. These variable control the verboseness of various tools within the system. The higher these numbers, the more verbose the tools become. This can be useful both when debugging proofs (with the simplifier for example), and also as a guide to how an automatic proof is proceeding (with mesonLib for example).

A call to trace nm v attempts to set the tracing variable associated with the string nm to value v. A tracing variable is associated with a string by registering it using the function register_trace.

Failure

Fails if the name given is not associated with a registered tracing variable.

Example

```
- REWRITE_CONV [] (Term'p /\ T /\ q');
> val it = |- p /\ T /\ q = p /\ q : Thm.thm
- trace "rewrite" 1;
> val it = () : unit
- REWRITE_CONV [] (Term'p /\ T /\ q');
<<HOL message: Rewrite:
|- T /\ q = q.>>
> val it = |- p /\ T /\ q = p /\ q : Thm.thm
```

See also

current_trace, register_trace, reset_trace, reset_traces, traces.

traces

traces : unit -> {name : string, current_value : int, default_value : int} list

Synopsis

Returns a list of registered tracing variables.

Failure

Never fails.

See also

```
current_trace, register_trace, reset_trace, reset_traces, trace.
```

TRANS

TRANS : (thm -> thm -> thm)

Synopsis

Uses transitivity of equality on two equational theorems.

Description

When applied to a theorem A1 |-t1 = t2 and a theorem A2 |-t2 = t3, the inference rule TRANS returns the theorem A1 u A2 |-t1 = t3. Note that TRANS can also be used as a infix (see example below).

A1 |-t1 = t2 A2 |-t2 = t3----- TRANS A1 u A2 |-t1 = t3

Failure

Fails unless the theorems are equational, with the right side of the first being the same as the left side of the second.

Example

The following shows identical uses of TRANS, one as a prefix, one an infix.

```
#let t1 = ASSUME "a:bool = b" and t2 = ASSUME "b:bool = c";;
t1 = . |- a = b
t2 = . |- b = c
#TRANS t1 t2;;
.. |- a = c
#t1 TRANS t2;;
.. |- a = c
```

See also

EQ_MP, IMP_TRANS, REFL, SYM.

TRY

TRY : (tactic -> tactic)

Synopsis

Makes a tactic have no effect rather than fail.

Description

For any tactic T, the application TRY T gives a new tactic which has the same effect as T if that succeeds, and otherwise has no effect.

Failure

The application of TRY to a tactic never fails. The resulting tactic never fails.

See also

CHANGED_TAC, VALID.

tryfind

tryfind : ((* -> **) -> * list -> **)

Synopsis

Returns the result of the first successful application of a function to the elements of a list.

Description

tryfind f [x1;...;xn] returns (f xi) for the first xi in the list for which application of f succeeds.

Failure

Fails with tryfind if the application of the function fails for all elements in the list. This will always be the case if the list is empty.

See also

```
find, mem, exists, forall, assoc, rev_assoc.
```

TRY_CONV

```
TRY_CONV : (conv -> conv)
```

Synopsis

Attempts to apply a conversion; applies identity conversion in case of failure.

Description

TRY_CONV c "t" attempts to apply the conversion c to the term "t"; if this fails, then the identity conversion applied instead. That is, if c is a conversion that maps a term "t" to the theorem |-t = t', then the conversion TRY_CONV c also maps "t" to |-t = t'. But if c fails when applied to "t", then TRY_CONV c "t" returns |-t = t.

454

Failure

Never fails.

See also

ALL_CONV.

types

types : string -> {Arity : int, Name : string} list

Synopsis

Lists the types in the named theory.

Description

The function types should be applied to a string which is the name of an ancestor theory (including the current theory; the special string "-" is always interpreted as the current theory). It returns a list of all the type constructors declared in the named theory, in the form of arity-name pairs.

Failure

Fails unless the named theory is an ancestor.

Example

The theory HOL has no types declared:

```
- types "HOL";
> val it = [] : (int # string) list
```

but its ancestors have the following types declared:

```
- itlist union (map types (ancestry "HOL")) [];
   > val it =
       [{Arity = 2, Name = "sum"}, {Arity = 2, Name = "prod"},
        {Arity = 0, Name = "num"}, {Arity = 1, Name = "list"},
        {Arity = 0, Name = "tree"}, {Arity = 1, Name = "ltree"},
        {Arity = 0, Name = "bool"}, {Arity = 0, Name = "ind"},
        {Arity = 2, Name = "fun"}, {Arity = 0, Name = "one"}]
       : {Arity : int, Name : string} list
}
\SEEALSO
ancestors, axioms, constants, definitions, infixes, new_type, new_type_abbrev,
new_type_definition, parents.
\ENDDOC
\DOC{type\_in}
\TYPE {\small\verb%type_in : (type -> term -> bool)%}\egroup
\SYNOPSIS
Determines whether any subterm of a given term has a particular type.
\DESCRIBE
The predicate {\small\verb%type_in%} returns {\small\verb%true%} if a subterm of the second arg
has the type specified by the first argument.
\EXAMPLE
{\par\samepage\setseps\small
\begin{verbatim}
#type_in ":num" "5 = 4 + 1";;
true : bool
#type_in ":bool" "5 = 4 + 1";;
true : bool
#type_in ":(num)list" "SUC 0";;
false : bool
See also
```

find_term, find_terms, type_in_type, type_tyvars.

type_in_type

```
type_in_type : (type -> type -> bool)
```

Synopsis

Determines whether a given type is a subtype of another.

Description

The predicate type_in_type returns true if the type given as the first argument is a subtype of the second.

Example

```
#type_in_type ":num" ":num # bool";;
true : bool
#type_in_type ":num" ":(num)list";;
true :bool
#type_in_type ":bool" ":num + bool";;
true : bool
```

See also

find_term, find_terms, type_in

type_lt

type_lt : hol_type -> hol_type -> unit

Synopsis

A total ordering function on types.

Description

type_lt tells whether one type is less than another in the ordering.

Failure

Never fails.

Example

```
- type_lt (==':bool'==) (==':'a -> 'a'==)
val it = true : bool
```

Comments

If not (type_lt ty1 ty2) and not (type_lt ty2 ty1), then ty1 = ty2, although it is faster to directly test for equality. Ordering of types may be useful in implementing search trees and the like.

See also

term_lt

type_of

type_of : (term -> type)

Synopsis

Returns the type of a term.

Failure

Never fails.

Example

```
#type_of "T";;
":bool" : type
```

type_subst

type_subst : hol_type subst -> hol_type -> hol_type

Synopsis

Instantiates types in a type.

Description

If theta = [{redex1,residue1},...,{redexn,residuen}] is a hol_type subst, where the redexi are the types to be substituted for, and the residuei the replacements, and ty is a type to instantiate, the call

type_subst theta ty

will appropriately instantiate the type ty. The instantiations will be performed in parallel. If several of the type instantiations are applicable, the choice is undefined. Each redexi ought to be a type variable, but if it isn't, it will never be replaced. Also, it is not necessary that any or all of the types t1...tn should in fact appear in ty.

Failure

Never fails.

Example

See also inst, INST_TYPE.

type_tyvars

type_tyvars : (type -> type list)

Synopsis

Determines the type variables of a given type.

Description

The function type_tyvars returns a list of type variables used to construct the given type.

Example

```
#type_tyvars ":bool";;
[] : type list
#type_tyvars ":(* -> **) -> (bool # ***) -> (** + num)";;
[":*"; ":**"; ":***"] : type list
```

See also

type_abbrevs, type_in, type_in_type.

tyvars

Compat.tyvars : term -> type list

Synopsis

Returns a list of the type variables free in a term.

Description

Found in the hol88 library. When applied to a term, tyvars returns a list (possibly empty) of the type variables which are free in the term.

Failure

Never fails. The function is not accessible unless the hol88 library has been loaded.

Example

```
- theorem "pair" "PAIR";
|- !x. (FST x,SND x) = x
- Compat.tyvars (concl PAIR);
val it = [(==':'b'==),(==':'a'==)] : hol_type list
- Compat.tyvars (--'x + 1 = SUC x'--);
[] : hol_type list
```

Comments

tyvars does not appear in hol90; use type_vars_in_term instead. WARNING: the order of the list returned from tyvars need not be the same as that returned from type_vars_in_term.

In the current HOL logic, there is no binding operation for types, so 'is free in' is synonymous with 'appears in'.

See also tyvars1.

tyvarsl

Compat.tyvarsl : (term list -> type list)

Synopsis

Returns a list of the type variables free in a list of terms.

Description

Found in the hol88 library. When applied to a list of terms, tyvars1 returns a list (possibly empty) of the type variables which are free in any of those terms.

Failure

Never fails. The function is not accessible unless the hol88 library has been loaded.

Example

- tyvarsl [--'!x. x = 1'--, --'!x:'a. x = x'--]; [(==':'a'==)] : hol_type list

Uses

Finding all the free type variables in the assumptions of a theorem, as a check on the validity of certain inferences.

Comments

tyvars1 does not appear in hol90. In the current HOL logic, there is no binding operation for types, so 'is free in' is synonymous with 'appears in'.

See also

tyvars.

uncurry

uncurry : ((* -> ** -> ***) -> (* # **) -> ***)

Synopsis

Converts a function taking two arguments into a function taking a single paired argument.

Description

The application uncurry f returns (x,y). f x y, so that

uncurry f (x,y) = f x y

Failure

Never fails.

See also

curry.

UNDISCH

UNDISCH : (thm -> thm)

Synopsis

Undischarges the antecedent of an implicative theorem.

Description

A |- t1 ==> t2 ----- UNDISCH A, t1 |- t2

Note that UNDISCH treats "~u" as "u ==> F".

Failure

UNDISCH will fail on theorems which are not implications or negations.

Comments

If the antecedent already appears in the hypotheses, it will not be duplicated. However, unlike DISCH, if the antecedent is alpha-equivalent to one of the hypotheses, it will still be added to the hypotheses.

See also

```
DISCH, DISCH_ALL, DISCH_TAC, DISCH_THEN, FILTER_DISCH_TAC, FILTER_DISCH_THEN, NEG_DISCH, STRIP_TAC, UNDISCH_ALL, UNDISCH_TAC.
```

462

UNDISCH_ALL

UNDISCH_ALL : (thm -> thm)

Synopsis

Iteratively undischarges antecedents in a chain of implications.

Description

A |- t1 ==> ... ==> tn ==> t ----- UNDISCH_ALL A, t1, ..., tn |- t

Note that UNDISCH_ALL treats "~u" as "u ==> F".

Failure

Unlike UNDISCH, UNDISCH_ALL will, when called on something other than an implication or negation, return its argument unchanged rather than failing.

Comments

Identical terms which are repeated in A, "t1", ..., "tn" will not be duplicated in the hypotheses of the resulting theorem. However, if two or more alpha-equivalent terms appear in A, "t1", ..., "tn", then each distinct term will appear in the result.

See also

DISCH, DISCH_ALL, DISCH_TAC, DISCH_THEN, NEG_DISCH, FILTER_DISCH_TAC, FILTER_DISCH_THEN, STRIP_TAC, UNDISCH, UNDISCH_TAC.

UNDISCH_TAC

UNDISCH_TAC : (term -> tactic)

Synopsis Undischarges an assumption.

Description

Failure

UNDISCH_TAC will fail if "v" is not an assumption.

Comments

UNDISCHarging "v" will remove all assumptions which are identical to "v", but those which are alpha-equivalent will remain.

See also

DISCH, DISCH_ALL, DISCH_TAC, DISCH_THEN, NEG_DISCH, FILTER_DISCH_TAC, FILTER_DISCH_THEN, STRIP_TAC, UNDISCH, UNDISCH_ALL.

UNDISCH_THEN

Thm_cont.UNDISCH_THEN : term -> thm_tactic -> tactic

Synopsis

Discharges the assumption given and passes it to a theorem-tactic.

Description

UNDISCH_THEN finds the first assumption equal to the term given, removes it from the assumption list, ASSUMES it, passes it to the theorem-tactic and then applies the consequent tactic. Thus:

```
UNDISCH_THEN t f ([a1,... ai, t, aj, ... an], goal) =
  f (ASSUME t) ([a1,... ai, aj,... an], goal)
```

For example, if

A u {t1} ?- t =========== f (ASSUME "t1") B u {t1} ?- v

then

A u {t1} ?- t ============ UNDISCH_THEN t1 f B ?- v

Failure

UNDISCH_THEN will fail on goals where the given term is not in the assumption list.

See also

```
PAT_ASSUM, DISCH, DISCH_ALL, DISCH_TAC, DISCH_THEN, NEG_DISCH, FILTER_DISCH_TAC, FILTER_DISCH_THEN, STRIP_TAC, UNDISCH, UNDISCH_ALL, UNDISCH_TAC.
```

union

```
union : ('a list -> 'a list -> 'a list)
```

Synopsis

Computes the union of two 'sets'.

Description

If 11 and 12 are both sets (a list with no repeated members), union 11 12 returns the set union of 11 and 12. In the case that 11 or 12 is not a set, all the user can depend on is that union 11 12 returns a list 13 such that every unique element of 11 and 12 is in 13 and each element of 13 is found in either 11 or 12.

Failure

Never fails.

Example

```
- union [1,2,3] [1,5,4,3];
val it = [2,1,5,4,3] : int list
- union [1,1,1] [1,2,3,2];
val it = [1,2,3,2] : int list
- union [1,2,3,2] [1,1,1] ;
val it = [3,2,1,1,1] : int list
```

Comments

Do not make the assumption that the order of items in the list is fixed. Later implementations may use different algorithms, and return a different concrete result while still meeting the specification.

High performance set operations may be found in the SML/NJ library.

See also

setify, set_equal, intersect, subtract.

variant

variant : (term list -> term -> term)

Synopsis

Modifies a variable name to avoid clashes.

Description

When applied to a list of variables to avoid clashing with, and a variable to modify, variant returns a variant of the variable to modify, that is, it changes the name as intuitively as possible to make it distinct from any variables in the list, or any (non-hidden) constants. This is normally done by adding primes to the name.

The exact form of the variable name should not be relied on, except that the original variable will be returned unmodified unless it is itself in the list to avoid clashing with.

Failure

variant 1 t fails if any term in the list 1 is not a variable or if t is not a variable.

version

Example

The following shows a couple of typical cases:

```
#variant ["y:bool"; "z:bool"] "x:bool";;
"x" : term
#variant ["x:bool"; "x':num"; "x'':num"] "x:bool";;
"x''' : term
```

while the following shows that clashes with the names of constants are also avoided:

```
#variant [] (mk_var('T',":bool"));;
"T'" : term
```

Uses

The function variant is extremely useful for complicated derived rules which need to rename variables to avoid free variable capture while still making the role of the variable obvious to the user.

Comments

The hol90 version of variant differs from that of hol88 by failing if asked to rename a constant.

See also

genvar, hide_constant, Compat.variant (in hol88 library).

version

Globals.version : string

Synopsis

The version of the HOL system being run.

Example

- Globals.version;

```
val it = "Athabasca" : string
```

W

W : ((* -> * -> **) -> * -> **)

Synopsis Duplicates function argument : W f x = f x x.

Failure Never fails.

See also

#, B, C, CB, Co, I, K, KI, o, oo, S.

words

words : (string -> string list)

Synopsis

Splits a string into a list of words.

Description

words s splits the string s into a list of substrings. Splitting occurs at each sequence of blanks and carriage returns (white space). This white space does not appear in the list of substrings. Leading and trailing white space in the input string is also thrown away.

Failure

Never fails.

Example

```
#words ' the cat sat on the mat ';;
['the'; 'cat'; 'sat'; 'on'; 'the'; 'mat'] : string list
```

Uses

Useful when wanting to map a function over a list of constant strings. Instead of using ['string1';...; 'stringn'] one can use:

```
(words 'string1 ... stringn')
```

See also

words2, word_separators, maptok, explode.

words2

```
words2 : (string -> string -> string list)
```

Synopsis

Splits a string into a list of substrings, breaking at occurrences of a specified character.

Description

words2 char s splits the string s into a list of substrings. Splitting occurs at each occurrence of a sequence of the character char. The char characters do not appear in the list of substrings. Leading and trailing occurrences of char are also thrown away. If char is not a single-character string (its length is not 1), then s will not be split and so the result will be the list [s].

Failure

Never fails.

Example

```
#words2 '/' '/the/cat//sat/on//the/mat/';;
['the'; 'cat'; 'sat'; 'on'; 'the'; 'mat'] : string list
#words2 '//' '/the/cat//sat/on//the/mat/';;
['/the/cat//sat/on//the/mat/'] : string list
```

See also

words, word_separators, explode.

X_CASES_THEN

X_CASES_THEN : (term list list -> thm_tactical)

Synopsis

Applies a theorem-tactic to all disjuncts of a theorem, choosing witnesses.

Description

Let [yl1;...;yln] represent a list of variable lists, each of length zero or more, and xl1,...,xln each represent a vector of zero or more variables, so that the variables in each of yl1...yln have the same types as the corresponding xli. X_CASES_THEN expects such a list of variable lists, [yl1;...;yln], a tactic generating function f:thm->tactic, and a disjunctive theorem, where each disjunct may be existentially quantified:

th = |-(?xl1.B1) \/...\/ (?xln.Bn)

each disjunct having the form (?xi1 ... xim. Bi). If applying f to the theorem obtained by introducing witness variables yli for the objects xli whose existence is asserted by each disjunct, typically ({Bi[yli/xli]} |- Bi[yli/xli]), produce the following results when applied to a goal (A ?- t):

```
A ?- t
======== f ({B1[y11/x11]} |- B1[y11/x11])
A ?- t1
...
A ?- t
======== f ({Bn[y1n/x1n]} |- Bn[y1n/x1n])
A ?- tn
```

then applying (X_CHOOSE_THEN [yl1;...;yln] f th) to the goal (A ?- t) produces n subgoals.

A ?- t =============== X_CHOOSE_THEN [yl1;...;yln] f th A ?- t1 ... A ?- tn

Failure

Fails (with X_CHOOSE_THEN) if any yli has more variables than the corresponding xli, or (with SUBST) if corresponding variables have different types. Failures may arise in the

tactic-generating function. An invalid tactic is produced if any variable in any of the yli is free in the corresponding Bi or in t, or if the theorem has any hypothesis which is not alpha-convertible to an assumption of the goal.

Example

Given the goal ?- (x MOD 2) <= 1, the following theorem may be used to split into 2 cases:

th = $|-(?m. x = 2 * m) \setminus / (?m. x = (2 * m) + 1)$

by the tactic X_CASES_THEN [["n:num"]; ["n:num"]] ASSUME_TAC th to produce the subgoals:

{x = (2 * n) + 1} ?- (x MOD 2) <= 1

 ${x = 2 * n}$?- (x MOD 2) <= 1

See also DISJ_CASES_THENL, X_CASES_THENL, X_CHOOSE_THEN.

X_CASES_THENL

X_CASES_THENL : (term list list -> thm_tactic list -> thm_tactic)

Synopsis

Applies theorem-tactics to corresponding disjuncts of a theorem, choosing witnesses.

Description

Let [yl1;...;yln] represent a list of variable lists, each of length zero or more, and xl1,...,xln each represent a vector of zero or more variables, so that the variables in each of yl1...yln have the same types as the corresponding xli. The function X_CASES_THENL expects a list of variable lists, [yl1;...;yln], a list of tactic-generating functions [f1;...;fn]:(thm->tactic)list, and a disjunctive theorem, where each disjunct may be existentially quantified:

th = |-(?xl1.B1) \/...\/ (?xln.Bn)

each disjunct having the form (?xi1 ... xim. Bi). If applying each fi to the theorem obtained by introducing witness variables yli for the objects xli whose existence is

asserted by the ith disjunct, ({Bi[yli/xli]} |- Bi[yli/xli]), produces the following results when applied to a goal (A ?- t):

```
A ?- t
========= f1 ({B1[yl1/xl1]} |- B1[yl1/xl1])
A ?- t1
...
A ?- t
======== fn ({Bn[yln/xln]} |- Bn[yln/xln])
A ?- tn
```

then applying X_CASES_THENL [yl1;...;yln] [f1;...;fn] th to the goal (A ?- t) produces n subgoals.

A ?- t ================== X_CASES_THENL [yl1;...;yln] [f1;...;fn] th A ?- t1 ... A ?- tn

Failure

Fails (with X_CASES_THENL) if any yli has more variables than the corresponding xli, or (with SUBST) if corresponding variables have different types, or (with combine) if the number of theorem tactics differs from the number of disjuncts. Failures may arise in the tactic-generating function. An invalid tactic is produced if any variable in any of the yli is free in the corresponding Bi or in t, or if the theorem has any hypothesis which is not alpha-convertible to an assumption of the goal.

Example

Given the goal $?-(x \mod 2) \le 1$, the following theorem may be used to split into 2 cases:

th = $|-(?m. x = 2 * m) \setminus / (?m. x = (2 * m) + 1)$

by the tactic X_CASES_THENL [["n:num"]; ["n:num"]] [ASSUME_TAC; SUBST1_TAC] th to produce the subgoals:

?- ((((2 * n) + 1) MOD 2) <= 1

 ${x = 2 * n} ?- (x MOD 2) <= 1$

See also

DISJ_CASES_THEN, X_CASES_THEN, X_CHOOSE_THEN.

X_CHOOSE_TAC

X_CHOOSE_TAC : (term -> thm_tactic)

Synopsis

Assumes a theorem, with existentially quantified variable replaced by a given witness.

Description

X_CHOOSE_TAC expects a variable y and theorem with an existentially quantified conclusion. When applied to a goal, it adds a new assumption obtained by introducing the variable y as a witness for the object x whose existence is asserted in the theorem.

A ?- t ================= X_CHOOSE_TAC "y" (A1 |- ?x. w) A u {w[y/x]} ?- t ("y" not free anywhere)

Failure

Fails if the theorem's conclusion is not existentially quantified, or if the first argument is not a variable. Failures may arise in the tactic-generating function. An invalid tactic is produced if the introduced variable is free in w or t, or if the theorem has any hypothesis which is not alpha-convertible to an assumption of the goal.

Example

Given a goal of the form

 ${n < m} ?- ?x. m = n + (x + 1)$

the following theorem may be applied:

th = ["n < m"] | - ?p. m = n + p

by the tactic (X_CHOOSE_TAC "q:num" th) giving the subgoal:

 ${n < m, m = n + q}$?- ?x. m = n + (x + 1)

CHOOSE, CHOOSE_THEN, X_CHOOSE_THEN.

X_CHOOSE_THEN

X_CHOOSE_THEN : (term -> thm_tactical)

Synopsis

Replaces existentially quantified variable with given witness, and passes it to a theoremtactic.

Description

X_CHOOSE_THEN expects a variable y, a tactic-generating function f:thm->tactic, and a theorem of the form (A1 |- ?x. w) as arguments. A new theorem is created by introducing the given variable y as a witness for the object x whose existence is asserted in the original theorem, (w[y/x] |- w[y/x]). If the tactic-generating function f applied to this theorem produces results as follows when applied to a goal (A ?- t):

```
A ?- t
======== f ({w[y/x]} |- w[y/x])
A ?- t1
```

then applying (X_CHOOSE_THEN "y" f (A1 |-?x.w)) to the goal (A ?- t) produces the subgoal:

A ?- t ======= X_CHOOSE_THEN "y" f (A1 |- ?x. w) A ?- t1 ("y" not free anywhere)

Failure

Fails if the theorem's conclusion is not existentially quantified, or if the first argument is not a variable. Failures may arise in the tactic-generating function. An invalid tactic is produced if the introduced variable is free in w or t, or if the theorem has any hypothesis which is not alpha-convertible to an assumption of the goal.

Example

Given a goal of the form

 ${n < m} ?- ?x. m = n + (x + 1)$

the following theorem may be applied:

th = ["n < m"] | - ?p. m = n + p

by the tactic (X_CHOOSE_THEN "q:num" SUBST1_TAC th) giving the subgoal:

 ${n < m} ?- ?x. n + q = n + (x + 1)$

X_FUN_EQ_CONV

X_FUN_EQ_CONV : (term -> conv)

Synopsis

Performs extensionality conversion for functions (function equality).

Description

The conversion X_FUN_EQ_CONV embodies the fact that two functions are equal precisely when they give the same results for all values to which they can be applied. For any variable "x" and equation "f = g", where x is of type ty1 and f and g are functions of type ty1->ty2, a call to X_FUN_EQ_CONV "x" "f = g" returns the theorem:

|-(f = g) = (!x. f x = g x)

Failure

 $X_FUN_EQ_CONV \ge tm$ fails if x is not a variable or if tm is not an equation f = g where f and g are functions. Furthermore, if f and g are functions of type ty1->ty2, then the variable \ge must have type ty1; otherwise the conversion fails. Finally, failure also occurs if x is free in either f or g.

See also EXT, FUN_EQ_CONV.

X_GEN_TAC

```
X_GEN_TAC : (term -> tactic)
```

Synopsis

Specializes a goal with the given variable.

Description

When applied to a term x', which should be a variable, and a goal A ?- !x. t, the tactic X_GEN_TAC returns the goal A ?- t[x'/x].

A ?- !x. t =========== X_GEN_TAC "x'" A ?- t[x'/x]

Failure

Fails unless the goal's conclusion is universally quantified and the term a variable of the appropriate type. It also fails if the variable given is free in either the assumptions or (initial) conclusion of the goal.

FILTER_GEN_TAC, GEN, GENL, GEN_ALL, SPEC, SPECL, SPEC_ALL, SPEC_TAC, STRIP_TAC.

X_SKOLEM_CONV

```
X_SKOLEM_CONV : (term -> conv)
```

Synopsis

Introduces a user-supplied Skolem function.

Description

X_SKOLEM_CONV takes two arguments. The first is a variable f, which must range over functions of the appropriate type, and the second is a term of the form !x1...xn. ?y. P. Given these arguments, X_SKOLEM_CONV returns the theorem:

|- (!x1...xn. ?y. P) = (?f. !x1...xn. tm[f x1 ... xn/y])

which expresses the fact that a skolem function f of the universally quantified variables x1...xn may be introduced in place of the the existentially quantified value y.

Failure

X_SKOLEM_CONV f tm fails if f is not a variable, or if the input term tm is not a term of the form !x1...xn. ?y. P, or if the variable f is free in tm, or if the type of f does not match its intended use as an n-place curried function from the variables x1...xn to a value having the same type as y.
