7.7.3 Measurability

There are two natural sigma-algebras on a product space: the borel sigma algebra, generated by open sets in the product, and the product sigma algebra, countably generated by products of measurable sets along finitely many coordinates. The second one is defined and studied in `Finite_Product_Measure.thy`.

These sigma-algebra share a lot of natural properties (measurability of coordinates, for instance), but there is a fundamental difference: open sets are generated by arbitrary unions, not only countable ones, so typically many open sets will not be measurable with respect to the product sigma algebra (while all sets in the product sigma algebra are borel). The two sigma algebras coincide only when everything is countable (i.e., the product is countable, and the borel sigma algebra in the factor is countably generated).

In this paragraph, we develop basic measurability properties for the borel sigma algebra, and compare it with the product sigma algebra as explained above.

lemma *measurable_product_coordinates* [*measurable* (*raw*)]:
(λ*x*. *x i*) ∈ *measurable borel borel*

by (*rule borel_measurable_continuous_onI*[*OF continuous_on_product_coordinates*])

lemma *measurable_product_then_coordinatewise*:
fixes f::$'a \Rightarrow 'b \Rightarrow$ ($'c$::*topological_space*)
assumes [*measurable*]: $f \in$ *borel_measurable M*
shows $(\lambda x.\ f\ x\ i) \in$ *borel_measurable M*
proof −
have $(\lambda x.\ f\ x\ i) = (\lambda y.\ y\ i)\ o\ f$
unfolding *comp_def* **by** *auto*
then show *?thesis* **by** *simp*
qed

To compare the Borel sigma algebra with the product sigma algebra, we give a presentation of the product sigma algebra that is more similar to the one we used above for the product topology.

No formalisation of Liouville's Approximation Theorem because this is already in the AFP as Liouville_Numbers. Apostol's Theorem 7.5 should be exactly the theorem liouville_irrational_algebraic. There is a minor discrepancy in the definition of "Liouville number" between Apostol and Eberl: he requires the denominator to be positive, while Eberl require it to exceed 1.

9.5 Scheffé's lemma

The next lemma shows that L^1 convergence of a sequence of functions follows from almost everywhere convergence and the weaker condition of the convergence of the integrated norms (or even just the nontrivial inequality about them). Useful in a lot of contexts! This statement (or its variations) are known as Scheffe lemma.

The formalization is more painful as one should jump back and forth between reals and ereals and justify all the time positivity or integrability (thankfully, measurability is handled more or less automatically).

9.7.4 Averaging Theorem

We aim to lift results from the real case to arbitrary Banach spaces. Our fundamental tool in this regard will be the averaging theorem. The proof of this theorem is due to Serge Lang (Real and Functional Analysis) [5]. The theorem allows us to make statements about a function's value almost everywhere, depending on the value its integral takes on various sets of the measure space.

Before we introduce and prove the averaging theorem, we will first show the following lemma which is crucial for our proof. While not stated exactly in this manner, our proof makes use of the characterization of second-countable topological spaces given in the book General Topology by Ryszard Engelking (Theorem 4.1.15) [4]. (Engelking's book *General Topology*)

lemma *balls_countable_basis*:

9.9.2 The Euler-Mascheroni constant

The limit of the difference between the partial harmonic sum and the natural logarithm (approximately 0.577216). This value occurs e.g. in the definition of the Gamma function.

definition *euler_mascheroni* :: *'a* :: *real_normed_algebra_1* **where**
euler_mascheroni = *of_real* (*lim* (λ*n*. *harm n* − *ln* (*of_nat n*)))

begin

Several equivalent definitions of the Gamma function and its most important properties. Also contains the definition and some properties of the log-Gamma function and the Digamma function and the other Polygamma functions.

Based on the Gamma function, we also prove the Weierstraß product form of the sin function and, based on this, the solution of the Basel problem (the sum over all *1 / real* (n^2).

9.10.1 The Euler form and the logarithmic Gamma function

We define the Gamma function by first defining its multiplicative inverse *rGamma*. This is more convenient because *rGamma* is entire, which makes proofs of its properties more convenient because one does not have to watch out for discontinuities. (e.g. *rGamma* fulfils *rGamma z* = *z* ∗ *rGamma* (*z* + *1*) everywhere, whereas the Γ function does not fulfil the analogous equation on the non-positive integers)

We define the Γ function (resp. its reciprocale) in the Euler form. This form has the advantage that it is a relatively simple limit that converges everywhere. The limit at the poles is 0 (due to division by 0). The functional equation *Gamma* (*z* + *1*) = *z* ∗ *Gamma z* follows immediately from the definition.

definition *Gamma_series* :: ('*a* :: {*banach*,*real_normed_field*}) ⇒ *nat* ⇒ '*a* **where**

We now show that the series that defines the Γ function in the Euler form

converges and that the function defined by it is continuous on the complex halfspace with positive real part.

We do this by showing that the logarithm of the Euler series is continuous and converges locally uniformly, which means that the log-Gamma function defined by its limit is also continuous.

This will later allow us to lift holomorphicity and continuity from the log-Gamma function to the inverse of the Gamma function, and from that to the Gamma function itself.

definition *ln_Gamma_series* :: ('*a* :: {*banach*,*real_normed_field*,*ln*}) ⇒ *nat* ⇒ '*a* **where**
ln_Gamma_series z n = *z* ∗ *ln* (*of_nat n*) − *ln z* − (∑ *k*=*1*..*n*. *ln* (*z* / *of_nat k* + *1*))

definition *ln_Gamma_series'* :: ('*a* :: {*banach*,*real_normed_field*,*ln*}) ⇒ *nat* ⇒ '*a* **where**
ln_Gamma_series' z n =
− *euler_mascheroni*∗*z* − *ln z* + (∑ *k*=*1*..*n*. *z* / *of_nat n* − *ln* (*z* / *of_nat k* + *1*))

definition *ln_Gamma* :: ('*a* :: {*banach*,*real_normed_field*,*ln*}) ⇒ '*a* **where**
ln_Gamma z = *lim* (*ln_Gamma_series z*)

We now show that the log-Gamma series converges locally uniformly for all complex numbers except the non-positive integers. We do this by proving that the series is locally Cauchy.
