ARM® Architecture Reference Manual

ARMv7-A and ARMv7-R edition

ARM®

ARM DDI 0406C.b (ID072512)

ARM Architecture Reference Manual
ARMv7-A and ARMv7-R edition

Release Information

The following changes have been made to this document.

Change History

Date	Issue	Confidentiality	Change
05 April 2007	A	Non-Confidential	New edition for ARMv7-A and ARMv7-R architecture profiles. Document number changed from ARM DDI 0100 to ARM DDI 0406 and contents restructured.
29 April 2008	B	Non-Confidential	Addition of the VFP Half-precision and Multiprocessing Extensions, and many clarifications and enhancements.
23 November 2011	C (C.a)	Non-Confidential	Addition of the Virtualization Extensions, Large Physical Address Extension, Generic Timer Extension, and other additions. Many other clarifications and enhancements.
24 July 2012	C.b	Non-Confidential	Errata release for issue C.a.

Note that issue C.a, the first publication of issue C of this manual, was originally identified as issue C.

From ARMv7, the ARM® architecture defines different architectural profiles and this edition of this manual describes only the A and R profiles. For details of the documentation of the ARMv7-M profile see *Additional reading* on page xxiii. Before ARMv7 there was only a single *ARM Architecture Reference Manual*, with document number DDI 0100. The first issue of this was in February 1996, and the final issue, issue I, was in July 2005. For more information see *Additional reading* on page xxiii.

Proprietary Notice

Note

The term ARM can refer to versions of the ARM architecture, for example ARMv6 refers to version 6 of the ARM architecture. The context makes it clear when the term is used in this way.

ARM Architecture Reference Manual ARMv7-A and ARMv7-R edition

Preface
About this manual xiv
Using this manual xvi
Conventions xxi
Additional reading xxiii
Feedback xxiv

Part A Application Level Architecture

Chapter A1 Introduction to the ARM Architecture
A1.1 About the ARM architecture A1-28
A1.2 The instruction sets A1-29
A1.3 Architecture versions, profiles, and variants A1-30
A1.4 Architecture extensions A1-32
A1.5 The ARM memory model A1-35

Chapter A2 Application Level Programmers' Model
A2.1 About the Application level programmers' model A2-38
A2.2 ARM core data types and arithmetic A2-40
A2.3 ARM core registers A2-45
A2.4 The Application Program Status Register (APSR) A2-49
A2.5 Execution state registers A2-50
A2.6 Advanced SIMD and Floating-point Extensions A2-54
A2.7 Floating-point data types and arithmetic A2-63
A2.8 Polynomial arithmetic over {0, 1} A2-93
A2.9 Coprocessor support A2-94

A2.10 Thumb Execution Environment A2-95
A2.11 Jazelle direct bytecode execution support A2-97
A2.12 Exceptions, debug events and checks A2-102

Chapter A3 Application Level Memory Model
A3.1 Address space A3-106
A3.2 Alignment support A3-108
A3.3 Endian support A3-110
A3.4 Synchronization and semaphores A3-114
A3.5 Memory types and attributes and the memory order model A3-125
A3.6 Access rights A3-141
A3.7 Virtual and physical addressing A3-144
A3.8 Memory access order A3-145
A3.9 Caches and memory hierarchy A3-155

Chapter A4 The Instruction Sets
A4.1 About the instruction sets A4-160
A4.2 Unified Assembler Language A4-162
A4.3 Branch instructions A4-164
A4.4 Data-processing instructions A4-165
A4.5 Status register access instructions A4-174
A4.6 Load/store instructions A4-175
A4.7 Load/store multiple instructions A4-177
A4.8 Miscellaneous instructions A4-178
A4.9 Exception-generating and exception-handling instructions A4-179
A4.10 Coprocessor instructions A4-180
A4.11 Advanced SIMD and Floating-point load/store instructions A4-181
A4.12 Advanced SIMD and Floating-point register transfer instructions A4-183
A4.13 Advanced SIMD data-processing instructions A4-184
A4.14 Floating-point data-processing instructions A4-191

Chapter A5 ARM Instruction Set Encoding
A5.1 ARM instruction set encoding A5-194
A5.2 Data-processing and miscellaneous instructions A5-196
A5.3 Load/store word and unsigned byte A5-208
A5.4 Media instructions A5-209
A5.5 Branch, branch with link, and block data transfer A5-214
A5.6 Coprocessor instructions, and Supervisor Call A5-215
A5.7 Unconditional instructions A5-216

Chapter A6 Thumb Instruction Set Encoding
A6.1 Thumb instruction set encoding A6-220
A6.2 16-bit Thumb instruction encoding A6-223
A6.3 32-bit Thumb instruction encoding A6-230

Chapter A7 Advanced SIMD and Floating-point Instruction Encoding
A7.1 Overview A7-254
A7.2 Advanced SIMD and Floating-point instruction syntax A7-255
A7.3 Register encoding A7-259
A7.4 Advanced SIMD data-processing instructions A7-261
A7.5 Floating-point data-processing instructions A7-272
A7.6 Extension register load/store instructions A7-274
A7.7 Advanced SIMD element or structure load/store instructions A7-275
A7.8 8, 16, and 32-bit transfer between ARM core and extension registers A7-278
A7.9 64-bit transfers between ARM core and extension registers A7-279

Chapter A8 Instruction Details
A8.1 Format of instruction descriptions A8-282

A8.2 Standard assembler syntax fields A8-287
A8.3 Conditional execution A8-288
A8.4 Shifts applied to a register A8-291
A8.5 Memory accesses A8-294
A8.6 Encoding of lists of ARM core registers A8-295
A8.7 Additional pseudocode support for instruction descriptions A8-296
A8.8 Alphabetical list of instructions A8-300

Chapter A9 The ThumbEE Instruction Set
A9.1 About the ThumbEE instruction set A9-1112
A9.2 ThumbEE instruction set encoding A9-1115
A9.3 Additional instructions in Thumb and ThumbEE instruction sets A9-1116
A9.4 ThumbEE instructions with modified behavior A9-1117
A9.5 Additional ThumbEE instructions A9-1123

Part B System Level Architecture

Chapter B1 The System Level Programmers' Model
B1.1 About the System level programmers' model B1-1134
B1.2 System level concepts and terminology B1-1135
B1.3 ARM processor modes and ARM core registers B1-1139
B1.4 Instruction set states B1-1155
B1.5 The Security Extensions B1-1156
B1.6 The Large Physical Address Extension B1-1159
B1.7 The Virtualization Extensions B1-1161
B1.8 Exception handling B1-1164
B1.9 Exception descriptions B1-1204
B1.10 Coprocessors and system control B1-1225
B1.11 Advanced SIMD and floating-point support B1-1228
B1.12 Thumb Execution Environment B1-1239
B1.13 Jazelle direct bytecode execution B1-1240
B1.14 Traps to the hypervisor B1-1247

Chapter B2 Common Memory System Architecture Features
B2.1 About the memory system architecture B2-1264
B2.2 Caches and branch predictors B2-1266
B2.3 IMPLEMENTATION DEFINED memory system features B2-1291
B2.4 Pseudocode details of general memory system operations B2-1292

Chapter B3 Virtual Memory System Architecture (VMSA)
B3.1 About the VMSA B3-1308
B3.2 The effects of disabling MMUs on VMSA behavior B3-1314
B3.3 Translation tables B3-1318
B3.4 Secure and Non-secure address spaces B3-1323
B3.5 Short-descriptor translation table format B3-1324
B3.6 Long-descriptor translation table format B3-1338
B3.7 Memory access control B3-1356
B3.8 Memory region attributes B3-1366
B3.9 Translation Lookaside Buffers (TLBs) B3-1378
B3.10 TLB maintenance requirements B3-1381
B3.11 Caches in a VMSA implementation B3-1392
B3.12 VMSA memory aborts B3-1395
B3.13 Exception reporting in a VMSA implementation B3-1409
B3.14 Virtual Address to Physical Address translation operations B3-1438
B3.15 About the system control registers for VMSA B3-1444
B3.16 Organization of the CP14 registers in a VMSA implementation B3-1468
B3.17 Organization of the CP15 registers in a VMSA implementation B3-1469

B3.18 Functional grouping of VMSAv7 system control registers B3-1491
B3.19 Pseudocode details of VMSA memory system operations B3-1503

Chapter B4 System Control Registers in a VMSA implementation
B4.1 VMSA System control registers descriptions, in register order B4-1522
B4.2 VMSA system control operations described by function B4-1740

Chapter B5 Protected Memory System Architecture (PMSA)
B5.1 About the PMSA B5-1754
B5.2 Memory access control B5-1759
B5.3 Memory region attributes B5-1760
B5.4 PMSA memory aborts B5-1763
B5.5 Exception reporting in a PMSA implementation B5-1767
B5.6 About the system control registers for PMSA B5-1772
B5.7 Organization of the CP14 registers in a PMSA implementation B5-1784
B5.8 Organization of the CP15 registers in a PMSA implementation B5-1785
B5.9 Functional grouping of PMSAv7 system control registers B5-1797
B5.10 Pseudocode details of PMSA memory system operations B5-1804

Chapter B6 System Control Registers in a PMSA implementation
B6.1 PMSA System control registers descriptions, in register order B6-1808
B6.2 PMSA system control operations described by function B6-1941

Chapter B7 The CPUID Identification Scheme
B7.1 Introduction to the CPUID scheme B7-1948
B7.2 The CPUID registers B7-1949
B7.3 Advanced SIMD and Floating-point Extension feature identification registers B7-1955

Chapter B8 The Generic Timer
B8.1 About the Generic Timer B8-1958
B8.2 Generic Timer registers summary B8-1967

Chapter B9 System Instructions
B9.1 General restrictions on system instructions B9-1970
B9.2 Encoding and use of Banked register transfer instructions B9-1971
B9.3 Alphabetical list of instructions B9-1976

Part C Debug Architecture

Chapter C1 Introduction to the ARM Debug Architecture
C1.1 Scope of part C of this manual C1-2020
C1.2 About the ARM Debug architecture C1-2021
C1.3 Security Extensions and debug C1-2025
C1.4 Register interfaces C1-2026

Chapter C2 Invasive Debug Authentication
C2.1 About invasive debug authentication C2-2028
C2.2 Invasive debug with no Security Extensions C2-2029
C2.3 Invasive debug with the Security Extensions C2-2031
C2.4 Invasive debug authentication security considerations C2-2033

Chapter C3 Debug Events
C3.1 About debug events C3-2036
C3.2 BKPT instruction debug events C3-2038
C3.3 Breakpoint debug events C3-2039
C3.4 Watchpoint debug events C3-2057

C3.5 Vector catch debug events C3-2065
C3.6 Halting debug events C3-2073
C3.7 Generation of debug events C3-2074
C3.8 Debug event prioritization C3-2076
C3.9 Pseudocode details of Software debug events C3-2078

Chapter C4 Debug Exceptions
C4.1 About debug exceptions C4-2088
C4.2 Avoiding debug exceptions that might cause UNPREDICTABLE behavior C4-2090

Chapter C5 Debug State
C5.1 About Debug state C5-2092
C5.2 Entering Debug state C5-2093
C5.3 Executing instructions in Debug state C5-2096
C5.4 Behavior of non-invasive debug in Debug state C5-2104
C5.5 Exceptions in Debug state C5-2105
C5.6 Memory system behavior in Debug state C5-2109
C5.7 Exiting Debug state C5-2110

Chapter C6 Debug Register Interfaces
C6.1 About the debug register interfaces C6-2114
C6.2 Synchronization of debug register updates C6-2115
C6.3 Access permissions C6-2117
C6.4 The CP14 debug register interface C6-2121
C6.5 The memory-mapped and recommended external debug interfaces C6-2126
C6.6 Summary of the v7 Debug register interfaces C6-2128
C6.7 Summary of the v7.1 Debug register interfaces C6-2137

Chapter C7 Debug Reset and Powerdown Support
C7.1 Debug guidelines for systems with energy management capability C7-2148
C7.2 Power domains and debug C7-2149
C7.3 The OS Save and Restore mechanism C7-2152
C7.4 Reset and debug C7-2160

Chapter C8 The Debug Communications Channel and Instruction Transfer Register
C8.1 About the DCC and DBGITR C8-2164
C8.2 Operation of the DCC and Instruction Transfer Register C8-2167
C8.3 Behavior of accesses to the DCC registers and DBGITR C8-2171
C8.4 Synchronization of accesses to the DCC and the DBGITR C8-2176

Chapter C9 Non-invasive Debug Authentication
C9.1 About non-invasive debug authentication C9-2182
C9.2 Non-invasive debug authentication C9-2183
C9.3 Effects of non-invasive debug authentication C9-2185

Chapter C10 Sample-based Profiling
C10.1 Sample-based profiling C10-2188

Chapter C11 The Debug Registers
C11.1 About the debug registers C11-2192
C11.2 Debug register summary C11-2193
C11.3 Debug identification registers C11-2196
C11.4 Control and status registers C11-2197
C11.5 Instruction and data transfer registers C11-2198
C11.6 Software debug event registers C11-2199
C11.7 Sample-based profiling registers C11-2200
C11.8 OS Save and Restore registers C11-2201

C11.9 Memory system control registers C11-2202
C11.10 Management registers C11-2203
C11.11 Register descriptions, in register order C11-2209

Chapter C12 The Performance Monitors Extension
C12.1 About the Performance Monitors C12-2300
C12.2 Accuracy of the Performance Monitors C12-2304
C12.3 Behavior on overflow C12-2305
C12.4 Effect of the Security Extensions and Virtualization Extensions C12-2307
C12.5 Event filtering, PMUv2 ..... C12-2309
C12.6 Counter enables C12-2311
C12.7 Counter access C12-2312
C12.8 Event numbers and mnemonics C12-2313
C12.9 Performance Monitors registers C12-2326

Part D Appendixes

Appendix A Recommended External Debug Interface
A.1 About the recommended external debug interface AppxA-2336
A.2 Authentication signals AppxA-2338
A.3 Run-control and cross-triggering signals AppxA-2340
A.4 Recommended debug slave port AppxA-2344
A.5 Other debug signals AppxA-2346

Appendix B Recommended Memory-mapped and External Debug Interfaces for the Performance Monitors
B.1 About the memory-mapped views of the Performance Monitors registers AppxB-2352
B.2 PMU register descriptions for memory-mapped register views AppxB-2361

Appendix C Recommendations for Performance Monitors Event Numbers for IMPLEMENTATION DEFINED Events
C.1 ARM recommendations for IMPLEMENTATION DEFINED event numbers AppxC-2376

Appendix D Example OS Save and Restore Sequences for External Debug Over Powerdown
D.1 Example OS Save and Restore sequences for v7 Debug AppxD-2388
D.2 Example OS Save and Restore sequences for v7.1 Debug AppxD-2392

Appendix E System Level Implementation of the Generic Timer
E.1 About the Generic Timer specification AppxE-2396
E.2 Memory-mapped counter module AppxE-2397
E.3 Counter module control and status register summary AppxE-2400
E.4 About the memory-mapped view of the counter and timer AppxE-2402
E.5 The CNTBaseN and CNTPL0BaseN frames AppxE-2403
E.6 The CNTCTLBase frame AppxE-2405
E.7 System level Generic Timer register descriptions, in register order AppxE-2406
E.8 Providing a complete set of counter and timer features AppxE-2423
E.9 Gray-count scheme for timer distribution scheme AppxE-2425

Appendix F Common VFP Subarchitecture Specification
F.1 Scope of this appendix AppxF-2429
F.2 Introduction to the Common VFP subarchitecture AppxF-2430
F.3 Exception processing AppxF-2432
F.4 Support code requirements AppxF-2436
F.5 Context switching AppxF-2438
F.6 Subarchitecture additions to the Floating-point Extension system registers AppxF-2439

F.7 Earlier versions of the Common VFP subarchitecture AppxF-2446

Appendix G Barrier Litmus Tests
G.1 Introduction AppxG-2448
G.2 Simple ordering and barrier cases AppxG-2451
G.3 Exclusive accesses and barriers AppxG-2458
G.4 Using a mailbox to send an interrupt AppxG-2460
G.5 Cache and TLB maintenance operations and barriers AppxG-2461

Appendix H Legacy Instruction Mnemonics
H.1 Thumb instruction mnemonics AppxH-2468
H.2 Other UAL mnemonic changes AppxH-2469
H.3 Pre-UAL pseudo-instruction NOP AppxH-2472

Appendix I Deprecated and Obsolete Features
I.1 Deprecated features AppxI-2474
I.2 Obsolete features AppxI-2483
I.3 Use of the SP as a general-purpose register AppxI-2484
I.4 Explicit use of the PC in ARM instructions AppxI-2485
I.5 Deprecated Thumb instructions AppxI-2486

Appendix J Fast Context Switch Extension (FCSE)
J.1 About the FCSE AppxJ-2488
J.2 Modified virtual addresses AppxJ-2489
J.3 Debug and trace AppxJ-2491

Appendix K VFP Vector Operation Support
K.1 About VFP vector mode AppxK-2494
K.2 Vector length and stride control AppxK-2495
K.3 VFP register banks AppxK-2496
K.4 VFP instruction type selection AppxK-2497

Appendix L ARMv6 Differences
L.1 Introduction to ARMv6 ..... AppxL-2500
L.2 Application level register support AppxL-2501
L.3 Application level memory support AppxL-2504
L.4 Instruction set support AppxL-2508
L.5 System level register support AppxL-2513
L.6 System level memory model AppxL-2516
L.7 System Control coprocessor, CP15, support AppxL-2523

Appendix M v6 Debug and v6.1 Debug Differences
M.1 About v6 Debug and v6.1 Debug AppxM-2548
M.2 Invasive debug authentication, v6 Debug and v6.1 Debug AppxM-2549
M.3 Debug events, v6 Debug and v6.1 Debug AppxM-2550
M.4 Debug exceptions, v6 Debug and v6.1 Debug AppxM-2554
M.5 Debug state, v6 Debug and v6.1 Debug AppxM-2555
M.6 Debug register interfaces, v6 Debug and v6.1 Debug AppxM-2559
M.7 Reset and powerdown support AppxM-2562
M.8 The Debug Communications Channel and Instruction Transfer Register . AppxM-2563
M.9 Non-invasive debug authentication, v6 Debug and v6.1 Debug AppxM-2564
M.10 Sample-based profiling, v6 Debug and v6.1 Debug AppxM-2566
M.11 The debug registers, v6 Debug and v6.1 Debug AppxM-2567
M.12 Performance monitors, v6 Debug and v6.1 Debug AppxM-2578

Appendix N Secure User Halting Debug
N.1 About Secure User halting debug AppxN-2580

N.2 Invasive debug authentication in an implementation that supports SUHD AppxN-2581
N.3 Effects of SUHD on Debug state AppxN-2582

Appendix O ARMv4 and ARMv5 Differences
O.1 Introduction to ARMv4 and ARMv5 ..... AppxO-2588
O.2 Application level register support AppxO-2589
O.3 Application level memory support AppxO-2590
O.4 Instruction set support AppxO-2595
O.5 System level register support AppxO-2601
O.6 System level memory model AppxO-2604
O.7 System Control coprocessor, CP15 support AppxO-2612

Appendix P Pseudocode Definition
P.1 About the ARMv7 pseudocode AppxP-2642
P.2 Pseudocode for instruction descriptions AppxP-2643
P.3 Data types AppxP-2645
P.4 Expressions AppxP-2649
P.5 Operators and built-in functions AppxP-2651
P.6 Statements and program structure AppxP-2656
P.7 Miscellaneous helper procedures and functions AppxP-2660

Appendix Q Pseudocode Index
Q.1 Pseudocode operators and keywords AppxQ-2666
Q.2 Pseudocode functions and procedures AppxQ-2669

Appendix R Register Index
R.1 Alphabetic index of ARMv7 registers, by register name AppxR-2684
R.2 Full registers index AppxR-2695

Glossary

Preface

This preface introduces the *ARM® Architecture Reference Manual, ARM®v7-A and ARM®v7-R edition*. It contains the following sections:

- *About this manual* on page xiv
- *Using this manual* on page xvi
- *Conventions* on page xxi
- *Additional reading* on page xxiii
- *Feedback* on page xxiv.

About this manual

This manual describes the A and R profiles of the ARM® architecture v7, ARMv7. It includes descriptions of:

- The processor instruction sets:
  - the original ARM instruction set
  - the high code density Thumb® instruction set
  - the ThumbEE instruction set, that includes specific support for *Just-In-Time* (JIT) or *Ahead-Of-Time* (AOT) compilation.
- The modes and states that determine how a processor operates, including the current execution privilege and security.
- The exception model.
- The memory model, that defines memory ordering and memory management:
  - the ARMv7-A architecture profile defines a *Virtual Memory System Architecture* (VMSA)
  - the ARMv7-R architecture profile defines a *Protected Memory System Architecture* (PMSA).
- The programmers' model, and its use of a coprocessor interface to access system control registers that control most processor and memory system features.
- The OPTIONAL *Floating-point* (VFP) Extension, that provides high-performance floating-point instructions that support:
  - single-precision and double-precision operations
  - conversions between double-precision, single-precision, and half-precision floating-point values.
- The OPTIONAL Advanced SIMD Extension, that provides high-performance integer and single-precision floating-point vector operations.
- The OPTIONAL Security Extensions, that facilitate the development of secure applications.
- The OPTIONAL Virtualization Extensions, that support the virtualization of Non-secure operation.
- The Debug architecture, that provides software access to debug features in the processor.

Note

ARMv7 introduces the architecture profiles. A separate Architecture Reference Manual describes the third profile, the Microcontroller profile, ARMv7-M. For more information see *Architecture versions, profiles, and variants* on page A1-30.

This manual gives the assembler syntax for the instructions it describes, meaning it can specify instructions in textual form. However, this manual is not a tutorial for ARM assembler language, nor does it describe ARM assembler language, except at a very basic level. To make effective use of ARM assembler language, read the documentation supplied with the assembler being used.

This manual is organized into parts:

Part A Describes the application level view of the architecture. It describes the application level view of the programmers' model and the memory model. It also describes the precise effects of each instruction in *User mode*, the normal operating mode, including any restrictions on its use. This information is of primary importance to authors and users of compilers, assemblers, and other programs that generate ARM machine code. Software execution in User mode is at the PL0 privilege level, also described as *unprivileged*.

Note

User mode is the only mode where software execution is unprivileged.

Part B Describes the system level view of the architecture. It gives details of system registers, most of which are not accessible from PL0, and the system level view of the memory model. It also gives full details of the effects of instructions executed with some level of *privilege*, where these are different from their effects in unprivileged execution.

Part C Describes the Debug architecture. This is an extension to the ARM architecture that provides configuration, breakpoint and watchpoint support, and a *Debug Communications Channel* (DCC) to a debug host.

Appendixes Provide additional information that is not part of the ARMv7 architectural requirements, including descriptions of:

- features that are recommended but not required
- differences in previous versions of the architecture.

Using this manual

The information in this manual is organized into parts, as described in this section.

Part A, Application Level Architecture

Part A describes the application level view of the architecture. It contains the following chapters:

Chapter A1 *Introduction to the ARM Architecture*

Gives an overview of the ARM architecture, and the ARM and Thumb instruction sets.

Chapter A2 *Application Level Programmers' Model*

Describes the application level view of the ARM programmers' model, including the application level view of the Advanced SIMD and Floating-point Extensions. It describes the types of values that ARM instructions operate on, the ARM core registers that contain those values, and the Application Program Status Register.

Chapter A3 *Application Level Memory Model*

Describes the application level view of the memory model, including the ARM memory types and attributes, and memory access control.

Chapter A4 *The Instruction Sets*

Describes the range of instructions available in the ARM, Thumb, Advanced SIMD, and VFP instruction sets. It also contains some details of instruction operation that are common to several instructions.

Chapter A5 *ARM Instruction Set Encoding*

Describes the encoding of the ARM instruction set.

Chapter A6 *Thumb Instruction Set Encoding*

Describes the encoding of the Thumb instruction set.

Chapter A7 *Advanced SIMD and Floating-point Instruction Encoding*

Describes the encoding of the Advanced SIMD and Floating-point Extension (VFP) instruction sets.

Chapter A8 *Instruction Details*

Gives a full description of every instruction available in the Thumb, ARM, Advanced SIMD, and Floating-point Extension instruction sets, with the exception of information only relevant to execution with some level of privilege.

Chapter A9 *The ThumbEE Instruction Set*

Gives a full description of the Thumb Execution Environment variant of the Thumb instruction set. This means it describes the ThumbEE instruction set.

Part B, System Level Architecture

Part B describes the system level view of the architecture. It contains the following chapters:

Chapter B1 *The System Level Programmers' Model*

Describes the system level view of the programmers' model.

Chapter B2 *Common Memory System Architecture Features*

Describes the system level view of the memory model features that are common to all memory systems.

Chapter B3 *Virtual Memory System Architecture (VMSA)*

Describes the system level view of the *Virtual Memory System Architecture* (VMSA) that is part of all ARMv7-A implementations. This chapter includes a description of the organization and general properties of the system control registers in a VMSA implementation.

Chapter B4 *System Control Registers in a VMSA implementation*

Describes all of the system control registers in VMSA implementation, including the registers that are part of the OPTIONAL extensions to a VMSA implementation. The registers are described in alphabetical order.

Chapter B5 *Protected Memory System Architecture (PMSA)*

Describes the system level view of the *Protected Memory System Architecture* (PMSA) that is part of all ARMv7-R implementations. This chapter includes a description of the organization and general properties of the system control registers in a PMSA implementation.

Chapter B6 *System Control Registers in a PMSA implementation*

Describes all of the system control registers in PMSA implementation, including the registers that are part of the OPTIONAL extensions to a PMSA implementation. The registers are described in alphabetical order.

Chapter B7 *The CPUID Identification Scheme*

Describes the CPUID scheme. This provides registers that identify the architecture version and many features of the processor implementation. This chapter also describes the registers that identify the implemented Advanced SIMD and VFP features, if any.

Chapter B8 *The Generic Timer*

Describes the OPTIONAL Generic Timer architecture extension.

Chapter B9 *System Instructions*

Provides detailed reference information about system instructions, and more information about instructions that behave differently when executed with some level of privilege.

Part C, Debug Architecture

Part C describes the Debug architecture. It contains the following chapters:

Chapter C1 *Introduction to the ARM Debug Architecture*

Introduces the Debug architecture, defining the scope of this part of the manual.

Chapter C2 *Invasive Debug Authentication*

Describes the authentication of invasive debug.

Chapter C3 *Debug Events*

Describes the debug events.

Chapter C4 *Debug Exceptions*

Describes the debug exceptions that handle debug events when the processor is configured for Monitor debug-mode.

Chapter C5 *Debug State*

Describes Debug state that is entered if a debug event occurs when the processor is configured for Halting debug-mode.

Chapter C6 *Debug Register Interfaces*

Describes the permitted debug register interfaces and the options for their implementation.

Chapter C7 *Debug Reset and Powerdown Support*

Describes the reset and powerdown support in the Debug architecture, including support for debug over powerdown.

Chapter C8 *The Debug Communications Channel and Instruction Transfer Register*

Describes the *Debug Communication Channel* (DCC) and *Instruction Transfer Register* (ITR), and how an external debugger uses these features to communicate with the debug logic.

Chapter C9 *Non-invasive Debug Authentication*

Describes the authentication of non-invasive debug.

Chapter C10 *Sample-based Profiling*

Describes sample-based profiling, that provides sampling of the program counter.

Chapter C11 *The Debug Registers*

Describes the debug registers.

Chapter C12 *The Performance Monitors Extension*

Describes the OPTIONAL Performance Monitors Extension.

Part D, Appendixes

This manual contains the following appendixes:

Appendix A *Recommended External Debug Interface*

Describes the recommended external interface to the ARM debug architecture.

Note

This description is not part of the ARM architecture specification. It is included here as supplementary information, for the convenience of developers and users who might require this information.

Appendix B *Recommended Memory-mapped and External Debug Interfaces for the Performance Monitors*

Describes the recommended external interfaces to the Performance Monitors Extension.

Note

This description is not part of the ARM architecture specification. It is included here as supplementary information, for the convenience of developers and users who might require this information.

Appendix C *Recommendations for Performance Monitors Event Numbers for IMPLEMENTATION DEFINED Events*

Gives the ARM recommendations for the use of the event numbers in the IMPLEMENTATION DEFINED event number space.

Note

This description is not part of the ARM architecture specification. It is included here as supplementary information, for the convenience of developers and users who might require this information.

Appendix D *Example OS Save and Restore Sequences for External Debug Over Powerdown*

Gives software examples that perform the OS Save and Restore sequences, for v7 Debug and v7.1 Debug implementations.

Note

Chapter C7 *Debug Reset and Powerdown Support* describes the OS Save and Restore mechanism, for both v7 Debug and v7.1 Debug.

Appendix E *System Level Implementation of the Generic Timer*

Contains the ARM Generic Timer architecture specification for the memory-mapped interface to the Generic Timer.

Note

This description is not part of the ARM architecture specification. It is included here as supplementary information, for the convenience of developers and users who might require this information.

Appendix F *Common VFP Subarchitecture Specification*

Defines version 2 of the Common VFP Subarchitecture.

Note

This specification is not part of the ARM architecture specification. This sub-architectural information is included here as supplementary information, for the convenience of developers and users who might require this information.

Appendix G *Barrier Litmus Tests*

Gives examples of the use of the barrier instructions provided by the ARMv7 architecture.

Note

These examples are not part of the ARM architecture specification. They are included here as supplementary information, for the convenience of developers and users who might require this information.

Appendix H *Legacy Instruction Mnemonics*

Describes the legacy mnemonics and their Unified Assembler Language equivalents.

Appendix I *Deprecated and Obsolete Features*

Lists the deprecated architectural features, with references to their descriptions in parts A to C of the manual.

Appendix J *Fast Context Switch Extension (FCSE)*

Describes the *Fast Context Switch Extension* (FCSE). See the appendix for information about the status of this in different versions of the ARM architecture.

Appendix K *VFP Vector Operation Support*

Describes the VFP vector operations. ARM deprecates the use of these operations.

Appendix L *ARMv6 Differences*

Describes how the ARMv6 architecture differs from the description given in parts A and B of this manual.

Appendix M *v6 Debug and v6.1 Debug Differences*

Describes how the two debug architectures for ARMv6 differ from the description given in part C of this manual.

Appendix N *Secure User Halting Debug*

Describes the *Secure User halting debug* (SUHD) feature.

Appendix O *ARMv4 and ARMv5 Differences*

Describes how the ARMv4 and ARMv5 architectures differ from the description given in parts A and B of this manual.

Appendix P *Pseudocode Definition*

The formal definition of the pseudocode used in this manual.

Appendix Q *Pseudocode Index*

Gives indexes to definitions of pseudocode operators, keywords, functions, and procedures.

Appendix R *Register Index*

Gives indexes to register descriptions in the manual.

Conventions

The following sections describe conventions that this book can use:

- *Typographic conventions*
- *Signals*
- *Numbers* on page xxii
- *Pseudocode descriptions* on page xxii
- *Assembler syntax descriptions* on page xxii.

Typographic conventions

The typographical conventions are:

italic Introduces special terminology, and denotes citations.

bold Denotes signal names, and is used for terms in descriptive lists, where appropriate.

`monospace` Used for assembler syntax descriptions, pseudocode, and source code examples.

Also used in the main text for instruction mnemonics and for references to other items appearing in assembler syntax descriptions, pseudocode, and source code examples.

SMALL CAPITALS

Used in body text for a few terms that have specific technical meanings, and are defined in the *Glossary*.

Colored text Indicates a link. This can be:

- a URL, for example, `http://infocenter.arm.com`
- a cross-reference, that includes the page number of the referenced information if it is not on the current page, for example, *Pseudocode descriptions* on page xxii
- a link, to a chapter or appendix, or to a glossary entry, or to the section of the document that defines the colored term, for example *Simple sequential execution* or SCTLR.

Note

Many links are to a register or instruction definition. Remember that:

- many system control registers are defined both in Chapter B4 *System Control Registers in a VMSA implementation* and in Chapter B6 *System Control Registers in a PMSA implementation*
- many instructions are defined in multiple forms, and in some cases the ARM encodings of an instruction are defined separately to the Thumb encodings.

Ensure that any linked definition you refer to is appropriate to your context.

Signals

In general this specification does not define processor signals, but it does include some signal examples and recommendations. The signal conventions are:

Signal level The level of an asserted signal depends on whether the signal is active-HIGH or active-LOW. Asserted means:

- HIGH for active-HIGH signals
- LOW for active-LOW signals.

Lower-case n At the start or end of a signal name denotes an active-LOW signal.

Numbers

Numbers are normally written in decimal. Binary numbers are preceded by `0b`, and hexadecimal numbers by `0x`. In both cases, the prefix and the associated value are written in a `monospace` font, for example `0xFFFF0000`.

Pseudocode descriptions

This manual uses a form of pseudocode to provide precise descriptions of the specified functionality. This pseudocode is written in a `monospace` font, and is described in Appendix P *Pseudocode Definition*.

Assembler syntax descriptions

This manual contains numerous syntax descriptions for assembler instructions and for components of assembler instructions. These are shown in a `monospace` font, and use the conventions described in *Assembler syntax* on page A8-283.

Additional reading

This section lists relevant publications from ARM and third parties.

See the Infocenter, http://infocenter.arm.com, for access to ARM documentation.

ARM publications

Feedback

ARM welcomes feedback on its documentation.

Feedback on this manual

If you have comments on the content of this manual, send e-mail to `errata@arm.com`. Give:

- the title
- the number, ARM DDI 0406C.b
- the page numbers to which your comments apply
- a concise explanation of your comments.

ARM also welcomes general suggestions for additions and improvements.

Part A

Application Level Architecture

Chapter A1
Introduction to the ARM Architecture

This chapter introduces the ARM architecture and contains the following sections:

- *About the ARM architecture* on page A1-28
- *The instruction sets* on page A1-29
- *Architecture versions, profiles, and variants* on page A1-30
- *Architecture extensions* on page A1-32
- *The ARM memory model* on page A1-35.

A1.1 About the ARM architecture

The ARM architecture supports implementations across a wide range of performance points. The architectural simplicity of ARM processors leads to very small implementations, and small implementations mean devices can have very low power consumption. Implementation size, performance, and very low power consumption are key attributes of the ARM architecture.

The ARM architecture is a *Reduced Instruction Set Computer* (RISC) architecture, as it incorporates these RISC architecture features:

- a large uniform register file
- a *load/store* architecture, where data-processing operations only operate on register contents, not directly on memory contents
- simple addressing modes, with all load/store addresses being determined from register contents and instruction fields only.

In addition, the ARM architecture provides:

- instructions that combine a shift with an arithmetic or logical operation
- auto-increment and auto-decrement addressing modes to optimize program loops
- Load and Store Multiple instructions to maximize data throughput
- conditional execution of many instructions to maximize execution throughput.

These enhancements to a basic RISC architecture mean ARM processors achieve a good balance of high performance, small program size, low power consumption, and small silicon area.

This Architecture Reference Manual defines a set of behaviors to which an implementation must conform, and a set of rules for software to use the implementation. It does not describe how to build an implementation.

Except where the architecture specifies differently, the programmer-visible behavior of an implementation must be the same as a simple sequential execution of the program. This programmer-visible behavior does not include the execution time of the program.

The ARM architecture includes definitions of:

- An associated debug architecture, see *Debug architecture versions* on page A1-31 and Part C of this manual.
- Associated trace architectures, that define trace macrocells that implementers can implement with the associated processor. For more information see the *Embedded Trace Macrocell Architecture Specification* and the *CoreSight Program Flow Trace Architecture Specification*.

A1.2 The instruction sets

The ARM instruction set is a set of 32-bit instructions providing comprehensive data-processing and control functions.

The Thumb instruction set was developed as a 16-bit instruction set with a subset of the functionality of the ARM instruction set. It provides significantly improved code density, at a cost of some reduction in performance. A processor executing Thumb instructions can change to executing ARM instructions for performance critical segments, in particular for handling interrupts.

ARMv6T2 introduced Thumb-2 technology. This technology extends the original Thumb instruction set with many 32-bit instructions. The range of 32-bit Thumb instructions included in ARMv6T2 permits Thumb code to achieve performance similar to ARM code, with code density better than that of earlier Thumb code.

From ARMv6T2, the ARM and Thumb instruction sets provide almost identical functionality. For more information, see Chapter A4 *The Instruction Sets*.

A1.2.1 Execution environment support

Two additional instruction sets support execution environments:

- The architecture can provide hardware acceleration of Java bytecodes. For more information, see:
  - *Jazelle direct bytecode execution support* on page A2-97, for application level information
  - *Jazelle direct bytecode execution* on page B1-1240, for system level information.

  The Virtualization Extensions do not support hardware acceleration of Java bytecodes. That is, they support only a trivial implementation of the Jazelle® extension.
- The ThumbEE instruction set is a variant of the Thumb instruction set that minimizes the code size overhead of a *Just-In-Time* (JIT) or *Ahead-Of-Time* (AOT) compiler. JIT and AOT compilers convert execution environment source code to a native executable. For more information, see:
  - *Thumb Execution Environment* on page A2-95, for application level information
  - *Thumb Execution Environment* on page B1-1239, for system level information.

  From the publication of issue C.a of this manual, ARM deprecates any use of the ThumbEE instruction set.

A1.3 Architecture versions, profiles, and variants

The ARM architecture has evolved significantly since its introduction, and ARM continues to develop it. Seven major versions of the architecture have been defined to date, denoted by the version numbers 1 to 7. Of these, the first three versions are now obsolete.

ARMv7 provides three profiles:

ARMv7-A Application profile, described in this manual:

- Implements a traditional ARM architecture with multiple modes.
- Supports a *Virtual Memory System Architecture* (VMSA) based on a *Memory Management Unit* (MMU). An ARMv7-A implementation can be called a VMSAv7 implementation.
- Supports the ARM and Thumb instruction sets.

ARMv7-R Real-time profile, described in this manual:

- Implements a traditional ARM architecture with multiple modes.
- Supports a *Protected Memory System Architecture* (PMSA) based on a *Memory Protection Unit* (MPU). An ARMv7-R implementation can be called a PMSAv7 implementation.
- Supports the ARM and Thumb instruction sets.

ARMv7-M Microcontroller profile, described in the *ARMv7-M Architecture Reference Manual*:

- Implements a programmers' model designed for low-latency interrupt processing, with hardware stacking of registers and support for writing interrupt handlers in high-level languages.
- Implements a variant of the ARMv7 PMSA.
- Supports a variant of the Thumb instruction set.

Note

Parts A, B, and C of this Architecture Reference Manual describe the ARMv7-A and ARMv7-R profiles:

- Appendixes describe how the ARMv4-ARMv6 architecture versions differ from ARMv7.
- Separate Architecture Reference Manuals define the M-profile architectures, see *Additional reading* on page xxiii.

Architecture versions can be qualified with variant letters to specify additional instructions and other functionality that are included as an architecture extension.

Some extensions are described separately instead of using a variant letter. For details of these extensions see *Architecture extensions* on page A1-32.

The valid variants of ARMv4, ARMv5, and ARMv6 are as follows:

ARMv4 The earliest architecture variant covered by this manual. It includes only the ARM instruction set.

ARMv4T Adds the Thumb instruction set.

ARMv5T Improves interworking of ARM and Thumb instructions. Adds Count Leading Zeros (`CLZ`) and software Breakpoint (`BKPT`) instructions.

ARMv5TE Enhances arithmetic support for *digital signal processing* (DSP) algorithms. Adds Preload Data (`PLD`), Load Register Dual (`LDRD`), Store Register Dual (`STRD`), and 64-bit coprocessor register transfer (`MCRR`, `MRRC`) instructions.

ARMv5TEJ Adds the `BXJ` instruction and other support for the Jazelle® architecture extension.

ARMv6 Adds many new instructions to the ARM instruction set. Formalizes and revises the memory model and the Debug architecture.

ARMv6K Adds instructions to support multiprocessing to the ARM instruction set, and some extra memory model features.

ARMv6T2 Introduces Thumb-2 technology, that supports a major development of the Thumb instruction set to provide a similar level of functionality to the ARM instruction set.

Note

Where appropriate, the terms ARMv6KZ or ARMv6Z describe the ARMv6K architecture with the ARMv6 Security Extensions, that were an OPTIONAL addition to the VMSAv6 architecture.

For detailed information about how earlier versions of the ARM architecture differ from ARMv7, see Appendix L *ARMv6 Differences* and Appendix O *ARMv4 and ARMv5 Differences*.

The following architecture variants are now obsolete:

ARMv1, ARMv2, ARMv2a, ARMv3, ARMv3G, ARMv3M, ARMv4xM, ARMv4TxM, ARMv5, ARMv5xM, ARMv5TxM, and ARMv5TExP.

Contact ARM if you require details of obsolete variants.

Each instruction description in this manual specifies the architecture versions that include the instruction.

A1.3.1 Debug architecture versions

Before ARMv6, the debug implementation for an ARM processor was IMPLEMENTATION DEFINED. ARMv6 defined the first debug architecture.

The debug architecture versions are:

v6 Debug Introduced with the original ARMv6 architecture definition.

v6.1 Debug Introduced to ARMv6K with the OPTIONAL Security Extensions, described in *Architecture extensions* on page A1-33. A VMSAv6 implementation that includes the Security Extensions must implement v6.1 Debug.

v7 Debug First defined in issue A of this manual, and required by any ARMv7-R implementation

An ARMv7-A implementation that does not include the Virtualization Extensions must implement either v7 Debug or v7.1 Debug.

For more information about the Virtualization Extensions, see *Architecture extensions* on page A1-33.

v7.1 Debug First defined in issue C.a of this manual, and required by any ARMv7-A implementation that includes the Virtualization Extensions.

For more information, see:

- Chapter C1 *Introduction to the ARM Debug Architecture*, for v7 Debug and v7.1 Debug
- *About v6 Debug and v6.1 Debug* on page AppxM-2548, for v6 Debug and v6.1 Debug.

Note

In this manual:

- debug usually refers to *invasive debug*, that permits modification of the state of the processor
- trace usually refers to *non-invasive debug*, that does not permit modification of the state of the processor.

For more information see *About the ARM Debug architecture* on page C1-2021.

A1.4 Architecture extensions

Instruction set architecture extensions summarizes the extensions that mainly affect the *Instruction Set Architecture* (ISA), either extending the instructions implemented in the ARM and Thumb instruction sets, or implementing an additional instruction set.

Architecture extensions on page A1-33 describes other extensions to the architecture.

A1.4.1 Instruction set architecture extensions

This manual describes the following extensions to the ISA:

Jazelle Is the Java bytecode execution extension that extended ARMv5TE to ARMv5TEJ. From ARMv6, the architecture requires at least the trivial Jazelle implementation, but a Jazelle implementation is still often described as a Jazelle extension.

The Virtualization Extensions require that the Jazelle implementation is the trivial Jazelle implementation.

ThumbEE Is a variant of the Thumb instruction set that is designed as a target for dynamically generated code. In the original release of the ARMv7 architecture, ThumbEE was:

- A required extension to the ARMv7-A profile.
- An optional extension to the ARMv7-R profile.

From publication of issue C.a of this manual, ARM deprecates any use of ThumbEE instructions. However, ARMv7-A implementations must continue to include ThumbEE support, for backwards compatibility.

Floating-point Is a floating-point coprocessor extension to the instruction set architectures. For historic reasons, the Floating-point Extension is also called the *VFP Extension*. There have been the following versions of the Floating-point (VFP) Extension:

VFPv1 Obsolete. Details are available on request from ARM.

VFPv2 An optional extension to:

- the ARM instruction set in the ARMv5TE, ARMv5TEJ, ARMv6, and ARMv6K architectures
- the ARM and Thumb instruction sets in the ARMv6T2 architecture.

VFPv3 An OPTIONAL extension to the ARM, Thumb, and ThumbEE instruction sets in the ARMv7-A and ARMv7-R profiles.

VFPv3 can be implemented with either thirty-two or sixteen doubleword registers, as described in *Advanced SIMD and Floating-point Extension registers* on page A2-56. Where necessary, the terms VFPv3-D32 and VFPv3-D16distinguish between these two implementation options. Where the term VFPv3 is used it covers both options.

VFPv3U is a variant of VFPv3 that supports the trapping of floating-point exceptions to support code, see *VFPv3U and VFPv4U* on page A2-62.

VFPv3 with Half-precision Extension

VFPv3 and VFPv3U can be extended by the OPTIONAL Half-precision Extension, that provides conversion functions in both directions between half-precision floating-point and single-precision floating-point.

VFPv4 An OPTIONAL extension to the ARM, Thumb, and ThumbEE instruction sets in the ARMv7-A and ARMv7-R profiles.

VFPv4U is a variant of VFPv4 that supports the trapping of floating-point exceptions to support code, see *VFPv3U and VFPv4U* on page A2-62.

VFPv4 and VFPv4U add both the Half-precision Extension and the fused multiply-add instructions to the features of VFPv3. VFPv4 can be implemented with either thirty-two or sixteen doubleword registers, see *Advanced SIMD and Floating-point Extension registers* on page A2-56. Where necessary, these implementation options are distinguished using the terms:

- VFPv4-D32, or VFPv4U-D32, for a thirty-two register implementation
- VFPv4-D16, or VFPv4U-D16, for a sixteen register implementation.

Where the term VFPv4 is used it covers both options.

If an implementation includes both the Floating-point and Advanced SIMD Extensions:

- It must implement the corresponding versions of the extensions:
  - if the implementation includes VFPv3 it must include Advanced SIMDv1
  - if the implementation includes VFPv3 with the Half-precision Extension it must include Advanced SIMDv1 with the half-precision extensions
  - if the implementation includes VFPv4 it must include Advanced SIMDv2.
- The two extensions use the same register bank. This means VFP must be implemented as VFPv3-D32, or as VFPv4-D32.
- Some instructions apply to both extensions.

Advanced SIMD Is an instruction set extension that provides *Single Instruction Multiple Data* (SIMD) integer and single-precision floating-point vector operations on doubleword and quadword registers. There have been the following versions of Advanced SIMD:

Advanced SIMDv1

It is an OPTIONAL extension to the ARMv7-A and ARMv7-R profiles.

Advanced SIMDv1 with Half-precision Extension

Advanced SIMDv1 can be extended by the OPTIONAL Half-precision Extension, that provides conversion functions in both directions between half-precision floating-point and single-precision floating-point.

Advanced SIMDv2

It is an OPTIONAL extension to the ARMv7-A and ARMv7-R profiles.

Advanced SIMDv2 adds both the Half-precision Extension and the fused multiply-add instructions to the features of Advanced SIMDv1.

See the description of the Floating-point Extension for more information about implementations that include both the Floating-point Extension and the Advanced SIMD Extension.

A1.4.2 Architecture extensions

This manual also describes the following extensions to the ARMv7 architecture:

Security Extensions

Are an OPTIONAL set of extensions to VMSAv6 implementations of the ARMv6K architecture, and to the ARMv7-A architecture profile, that provide a set of security features that facilitate the development of secure applications.

Multiprocessing Extensions

Are an OPTIONAL set of extensions to the ARMv7-A and ARMv7-R profiles, that provides a set of features that enhance multiprocessing functionality.

Large Physical Address Extension

Is an OPTIONAL extension to VMSAv7 that provides an address translation system supporting physical addresses of up to 40 bits at a fine grain of translation.

The Large Physical Address Extension requires implementation of the Multiprocessing Extensions.

Virtualization Extensions

Are an OPTIONAL set of extensions to VMSAv7 that provides hardware support for virtualizing the Non-secure state of a VMSAv7 implementation. This supports system use of a virtual machine monitor, also called a hypervisor, to switch Guest operating systems.

The Virtualization Extensions require implementation of:

- the Security Extensions
- the Large Physical Address Extension
- the v7.1 Debug architecture, see *Scope of part C of this manual* on page C1-2020.

If an implementation that includes the Virtualization Extensions also implements:

- The Performance Monitors Extension, then it must implement version 2 of that extension, PMUv2, see *About the Performance Monitors* on page C12-2300.
- A trace macrocell, that trace macrocell must support the Virtualization Extensions. In particular, if the trace macrocell is:
  - an *Embedded Trace Macrocell* (ETM), the macrocell must implement ETMv3.5 or later, see the *Embedded Trace Macrocell Architecture Specification*
  - a *Program Trace Macrocell* (PTM), the macrocell must implement PFTv1.1 or later, see the *CoreSight Program Flow Trace Architecture Specification*.

In some tables in this manual, an ARMv7-A implementation that includes the Virtualization Extensions is described as ARMv7VE, or as v7VE.

Generic Timer Extension

Is an OPTIONAL extension to any ARMv7-A or ARMv7-R, that provides a system timer, and a low-latency register interface to it.

This extension is introduced with the Large Physical Address Extension and Virtualization Extensions, but can be implemented with any earlier version of the ARMv7 architecture. The Generic Timer Extension does not require the implementation of any of the extensions described in this subsection.

For more information see Chapter B8 *The Generic Timer*.

Performance Monitors Extension

The ARMv7 architecture:

- reserves CP15 register space for IMPLEMENTATION DEFINED performance monitors
- defines a recommended performance monitors implementation.

From issue C.a of this manual, this recommended implementation is called the *Performance Monitors Extension*.

The Performance Monitors Extension does not require the implementation of any of the extensions described in this subsection.

If an ARMv7 implementation that includes v7.1 Debug also includes the Performance Monitors Extension, it must implement PMUv2.

For more information see Chapter C12 *The Performance Monitors Extension*.

Note

The *Fast Context Switch Extension* (FCSE) is an older ARM extension, described in Appendix J:

- ARM deprecates any use of this extension. This means in ARMv7 implementations before the introduction of the Multiprocessing Extensions, the FCSE is OPTIONAL and deprecated.
- The Multiprocessing Extensions obsolete the FCSE. This means that any processor that includes the Multiprocessing Extensions cannot include the FCSE. This includes all processors that implement the Large Physical Address Extension.

A1.5 The ARM memory model

The ARM instruction sets address a single, flat address space of 2^{32} 8-bit bytes. This address space is also regarded as 2^{30} 32-bit words or 2^{31} 16-bit halfwords.

The architecture provides facilities for:

- generating an exception on an unaligned memory access
- restricting access by applications to specified areas of memory
- translating virtual addresses provided by executing instructions into physical addresses
- altering the interpretation of word and halfword data between big-endian and little-endian
- controlling the order of accesses to memory
- controlling caches
- synchronizing access to shared memory by multiple processors.

For more information, see:

- Chapter A3 *Application Level Memory Model*
- Chapter B2 *Common Memory System Architecture Features*
- Chapter B3 *Virtual Memory System Architecture (VMSA)*
- Chapter B5 *Protected Memory System Architecture (PMSA)*.

Chapter A2
Application Level Programmers' Model

This chapter gives an application level view of the ARM programmers' model. It contains the following sections:

- *About the Application level programmers' model* on page A2-38
- *ARM core data types and arithmetic* on page A2-40
- *ARM core registers* on page A2-45
- *The Application Program Status Register (APSR)* on page A2-49
- *Execution state registers* on page A2-50
- *Advanced SIMD and Floating-point Extensions* on page A2-54
- *Floating-point data types and arithmetic* on page A2-63
- *Polynomial arithmetic over {0, 1}* on page A2-93
- *Coprocessor support* on page A2-94
- *Thumb Execution Environment* on page A2-95
- *Jazelle direct bytecode execution support* on page A2-97
- *Exceptions, debug events and checks* on page A2-102.

Note

In this chapter, system register names usually link to the description of the register in Chapter B4 *System Control Registers in a VMSA implementation*, for example FPSCR. If the register is included in a PMSA implementation, then it is also described in Chapter B6 *System Control Registers in a PMSA implementation*.

A2.1 About the Application level programmers' model

This chapter contains the programmers' model information required for application development.

The information in this chapter is distinct from the system information required to service and support application execution under an operating system, or higher level of system software. However, some knowledge of that system information is needed to put the Application level programmers' model into context.

Depending on the implemented architecture extensions, the architecture supports multiple levels of execution privilege, that number upwards from PL0, where PL0 is the lowest privilege level and is often described as unprivileged. The Application level programmers' model is the programmers' model for software executing at PL0. For more information see *Processor privilege levels, execution privilege, and access privilege* on page A3-141.

System software determines the privilege level at which application software runs. When an operating system supports execution at both PL1 and PL0, an application usually runs unprivileged. This:

- permits the operating system to allocate system resources to an application in a unique or shared manner
- provides a degree of protection from other processes and tasks, and so helps protect the operating system from malfunctioning applications.

This chapter indicates where some system level understanding is helpful, and if appropriate it gives a reference to the system level description in Chapter B1 *The System Level Programmers' Model*, or elsewhere.

The Security Extensions extend the architecture to provide hardware security features that support the development of secure applications, by providing two Security states. The Virtualization Extensions further extend the architecture to provide virtualization of operation in Non-secure state. However, application level software is generally unaware of these extensions. For more information, see *The Security Extensions* on page B1-1156 and *The Virtualization Extensions* on page B1-1161.

Note

- When an implementation includes the Security Extensions, application and operating system software normally executes in Non-secure state.
- The virtualization features accessible only at PL2 are implemented only in Non-secure state. Secure state has only two privilege levels, PL0 and PL1.
- Older documentation, describing implementations or architecture versions that support only two privilege levels, often refers to execution at PL1 as *privileged* execution.
- In this manual, the following terms have special meanings, defined in the *Glossary*:
  - IMPLEMENTATION DEFINED, see *IMPLEMENTATION DEFINED*.
  - OPTIONAL, see *OPTIONAL*.
  - SUBARCHITECTURE DEFINED, see *SUBARCHITECTURE DEFINED*.
  - UNDEFINED, see *UNDEFINED*.
  - UNKNOWN, see *UNKNOWN*.
  - UNPREDICTABLE, see *UNPREDICTABLE*.

A2.1.1 Instruction sets, arithmetic operations, and register files

The ARM and Thumb instruction sets both provide a wide range of integer arithmetic and logical operations, that operate on register file of sixteen 32-bit registers, the *ARM core registers*. As described in *ARM core registers* on page A2-45, these registers include the special registers SP, LR, and PC. *ARM core data types and arithmetic* on page A2-40 gives more information about these operations.

In addition, if an implementation includes:

- the Floating-point (VFP) Extension, the ARM and Thumb instruction sets include floating-point instructions
- the Advanced SIMD Extension, the ARM and Thumb instruction sets include vector instructions.

Floating-point and vector instructions operate on an independent register file, described in *Advanced SIMD and Floating-point Extension registers* on page A2-56. In an implementation that includes both of these extensions, they share a common register file. The following sections give more information about these extensions and the instructions they provide:

- *Advanced SIMD and Floating-point Extensions* on page A2-54
- *Floating-point data types and arithmetic* on page A2-63
- *Polynomial arithmetic over {0, 1}* on page A2-93.

A2.2 ARM core data types and arithmetic

All ARMv7-A and ARMv7-R processors support the following data types in memory:

Byte 8 bits
Halfword 16 bits
Word 32 bits
Doubleword 64 bits.

Processor registers are 32 bits in size. The instruction set contains instructions supporting the following data types held in registers:

- 32-bit pointers
- unsigned or signed 32-bit integers
- unsigned 16-bit or 8-bit integers, held in zero-extended form
- signed 16-bit or 8-bit integers, held in sign-extended form
- two 16-bit integers packed into a register
- four 8-bit integers packed into a register
- unsigned or signed 64-bit integers held in two registers.

Load and store operations can transfer bytes, halfwords, or words to and from memory. Loads of bytes or halfwords zero-extend or sign-extend the data as it is loaded, as specified in the appropriate load instruction.

The instruction sets include load and store operations that transfer two or more words to and from memory. Software can load and store doublewords using these instructions.

Note

For information about the atomicity of memory accesses see *Atomicity in the ARM architecture* on page A3-127.

When any of the data types is described as *unsigned*, the N-bit data value represents a non-negative integer in the range 0 to 2^N-1, using normal binary format.

When any of these types is described as *signed*, the N-bit data value represents an integer in the range -2^{N-1} to $+2^{N-1}$-1, using two's complement format.

The instructions that operate on packed halfwords or bytes include some multiply instructions that use just one of two halfwords, and SIMD instructions that perform parallel addition or subtraction on all of the halfwords or bytes.

Direct instruction support for 64-bit integers is limited, and most 64-bit operations require sequences of two or more instructions to synthesize them.

A2.2.1 Integer arithmetic

The instruction set provides a wide variety of operations on the values in registers, including bitwise logical operations, shifts, additions, subtractions, multiplications, and many others. The pseudocode described in Appendix P *Pseudocode Definition* defines these operations, usually in one of three ways:

- By direct use of the pseudocode operators and built-in functions defined in *Operators and built-in functions* on page AppxP-2651.
- By use of pseudocode helper functions defined in the main text. These can be located using the table in Appendix Q *Pseudocode Index*.
- By a sequence of the form:
  1. Use of the `SInt()`, `UInt()`, and `Int()` built-in functions defined in *Converting bitstrings to integers* on page AppxP-2653 to convert the bitstring contents of the instruction operands to the unbounded integers that they represent as two's complement or unsigned integers.
  2. Use of mathematical operators, built-in functions and helper functions on those unbounded integers to calculate other such integers.
  3. Use of either the bitstring extraction operator defined in *Bitstring extraction* on page AppxP-2652 or of the saturation helper functions described in *Pseudocode details of saturation* on page A2-44 to convert an unbounded integer result into a bitstring result that can be written to a register.

Shift and rotate operations

The following types of shift and rotate operations are used in instructions:

Logical Shift Left

(`LSL`) moves each bit of a bitstring left by a specified number of bits. Zeros are shifted in at the right end of the bitstring. Bits that are shifted off the left end of the bitstring are discarded, except that the last such bit can be produced as a carry output.

Logical Shift Right

(`LSR`) moves each bit of a bitstring right by a specified number of bits. Zeros are shifted in at the left end of the bitstring. Bits that are shifted off the right end of the bitstring are discarded, except that the last such bit can be produced as a carry output.

Arithmetic Shift Right

(`ASR`) moves each bit of a bitstring right by a specified number of bits. Copies of the leftmost bit are shifted in at the left end of the bitstring. Bits that are shifted off the right end of the bitstring are discarded, except that the last such bit can be produced as a carry output.

Rotate Right (`ROR`) moves each bit of a bitstring right by a specified number of bits. Each bit that is shifted off the right end of the bitstring is re-introduced at the left end. The last bit shifted off the right end of the bitstring can be produced as a carry output.

Rotate Right with Extend

(`RRX`) moves each bit of a bitstring right by one bit. A carry input is shifted in at the left end of the bitstring. The bit shifted off the right end of the bitstring can be produced as a carry output.

Pseudocode details of shift and rotate operations

These shift and rotate operations are supported in pseudocode by the following functions:

```
// LSL_C()
// =======

(bits(N), bit) LSL_C(bits(N) x, integer shift)
    assert shift > 0;
    extended_x = x : Zeros(shift);
    result = extended_x<N-1:0>;
    carry_out = extended_x<N>;
```

```
    return (result, carry_out);
// LSL()
// =====

bits(N) LSL(bits(N) x, integer shift)
    assert shift >= 0;
    if shift == 0 then
        result = x;
    else
        (result, -) = LSL_C(x, shift);
    return result;

// LSR_C()
// =======

(bits(N), bit) LSR_C(bits(N) x, integer shift)
    assert shift > 0;
    extended_x = ZeroExtend(x, shift+N);
    result = extended_x<shift+N-1:shift>;
    carry_out = extended_x<shift-1>;
    return (result, carry_out);

// LSR()
// =====

bits(N) LSR(bits(N) x, integer shift)
    assert shift >= 0;
    if shift == 0 then
        result = x;
    else
        (result, -) = LSR_C(x, shift);
    return result;

// ASR_C()
// =======

(bits(N), bit) ASR_C(bits(N) x, integer shift)
    assert shift > 0;
    extended_x = SignExtend(x, shift+N);
    result = extended_x<shift+N-1:shift>;
    carry_out = extended_x<shift-1>;
    return (result, carry_out);

// ASR()
// =====

bits(N) ASR(bits(N) x, integer shift)
    assert shift >= 0;
    if shift == 0 then
        result = x;
    else
        (result, -) = ASR_C(x, shift);
    return result;

// ROR_C()
// =======

(bits(N), bit) ROR_C(bits(N) x, integer shift)
    assert shift != 0;
    m = shift MOD N;
    result = LSR(x,m) OR LSL(x,N-m);
    carry_out = result<N-1>;
    return (result, carry_out);
```

```
// ROR()
// =====

bits(N) ROR(bits(N) x, integer shift)
    if shift == 0 then
        result = x;
    else
        (result, -) = ROR_C(x, shift);
    return result;

// RRX_C()
// =======

(bits(N), bit) RRX_C(bits(N) x, bit carry_in)
    result = carry_in : x<N-1:1>;
    carry_out = x<0>;
    return (result, carry_out);

// RRX()
// =====

bits(N) RRX(bits(N) x, bit carry_in)
    (result, -) = RRX_C(x, carry_in);
    return result;
```

Pseudocode details of addition and subtraction

In pseudocode, addition and subtraction can be performed on any combination of unbounded integers and bitstrings, provided that if they are performed on two bitstrings, the bitstrings must be identical in length. The result is another unbounded integer if both operands are unbounded integers, and a bitstring of the same length as the bitstring operand(s) otherwise. For the precise definition of these operations, see *Addition and subtraction* on page AppxP-2654.

The main addition and subtraction instructions can produce status information about both unsigned carry and signed overflow conditions. When necessary, multi-word additions and subtractions are synthesized from this status information. In pseudocode the `AddWithCarry()` function provides an addition with a carry input and carry and overflow outputs:

```
// AddWithCarry()
// ==============

(bits(N), bit, bit) AddWithCarry(bits(N) x, bits(N) y, bit carry_in)
    unsigned_sum = UInt(x) + UInt(y) + UInt(carry_in);
    signed_sum   = SInt(x) + SInt(y) + UInt(carry_in);
    result       = unsigned_sum<N-1:0>;  // same value as signed_sum<N-1:0>
    carry_out    = if UInt(result) == unsigned_sum then '0' else '1';
    overflow     = if SInt(result) == signed_sum then '0' else '1';
    return (result, carry_out, overflow);
```

An important property of the `AddWithCarry()` function is that if:

```
(result, carry_out, overflow) = AddWithCarry(x, NOT(y), carry_in)
```

then:

- if `carry_in == '1'`, then `result == x-y` with:
  - `overflow == '1'` if signed overflow occurred during the subtraction
  - `carry_out == '1'` if unsigned borrow did not occur during the subtraction, that is, if `x >= y`
- if `carry_in == '0'`, then `result == x-y-1` with:
  - `overflow == '1'` if signed overflow occurred during the subtraction
  - `carry_out == '1'` if unsigned borrow did not occur during the subtraction, that is, if `x > y`.

Together, these mean that the `carry_in` and `carry_out` bits in `AddWithCarry()` calls can act as *NOT borrow* flags for subtractions as well as *carry* flags for additions.

Pseudocode details of saturation

Some instructions perform *saturating arithmetic*, that is, if the result of the arithmetic overflows the destination signed or unsigned N-bit integer range, the result produced is the largest or smallest value in that range, rather than wrapping around modulo 2^N. This is supported in pseudocode by:

- the `SignedSatQ()` and `UnsignedSatQ()` functions when an operation requires, in addition to the saturated result, a Boolean argument that indicates whether saturation occurred
- the `SignedSat()` and `UnsignedSat()` functions when only the saturated result is required.

```
// SignedSatQ()
// ============

(bits(N), boolean) SignedSatQ(integer i, integer N)
    if i > 2^(N-1) - 1 then
        result = 2^(N-1) - 1;  saturated = TRUE;
    elsif i < -(2^(N-1)) then
        result = -(2^(N-1));  saturated = TRUE;
    else
        result = i;  saturated = FALSE;
    return (result<N-1:0>, saturated);
// UnsignedSatQ()
// ==============

(bits(N), boolean) UnsignedSatQ(integer i, integer N)
    if i > 2^N - 1 then
        result = 2^N - 1;  saturated = TRUE;
    elsif i < 0 then
        result = 0;  saturated = TRUE;
    else
        result = i;  saturated = FALSE;
    return (result<N-1:0>, saturated);

// SignedSat()
// ===========

bits(N) SignedSat(integer i, integer N)
    (result, -) = SignedSatQ(i, N);
    return result;

// UnsignedSat()
// =============

bits(N) UnsignedSat(integer i, integer N)
    (result, -) = UnsignedSatQ(i, N);
    return result;
```

`SatQ(i, N, unsigned)` returns either `UnsignedSatQ(i, N)` or `SignedSatQ(i, N)` depending on the value of its third argument, and `Sat(i, N, unsigned)` returns either `UnsignedSat(i, N)` or `SignedSat(i, N)` depending on the value of its third argument:

```
// SatQ()
// ======

(bits(N), boolean) SatQ(integer i, integer N, boolean unsigned)
    (result, sat) = if unsigned then UnsignedSatQ(i, N) else SignedSatQ(i, N);
    return (result, sat);
// Sat()
// =====

bits(N) Sat(integer i, integer N, boolean unsigned)
    result = if unsigned then UnsignedSat(i, N) else SignedSat(i, N);
    return result;
```

A2.3 ARM core registers

In the application level view, an ARM processor has:

- thirteen general-purpose 32-bit registers, R0 to R12
- three 32-bit registers with special uses, SP, LR, and PC, that can be described as R13 to R15.

The special registers are:

SP, the stack pointer

The processor uses SP as a pointer to the active stack.

In the Thumb instruction set, most instructions cannot access SP. The only instructions that can access SP are those designed to use SP as a stack pointer.

The ARM instruction set provides more general access to the SP, and it can be used as a general-purpose register. However, ARM deprecates the use of SP for any purpose other than as a stack pointer.

Note

Using SP for any purpose other than as a stack pointer is likely to break the requirements of operating systems, debuggers, and other software systems, causing them to malfunction.

Software can refer to SP as R13.

LR, the link register

The link register is a special register that can hold return link information. Some cases described in this manual require this use of the LR. When software does not require the LR for linking, it can use it for other purposes. It can refer to LR as R14.

PC, the program counter

- When executing an ARM instruction, PC reads as the address of the current instruction plus 8.
- When executing a Thumb instruction, PC reads as the address of the current instruction plus 4.
- Writing an address to PC causes a branch to that address.

Most Thumb instructions cannot access PC.

The ARM instruction set provides more general access to the PC, and many ARM instructions can use the PC as a general-purpose register. However, ARM deprecates the use of PC for any purpose other than as the program counter. See *Writing to the PC* on page A2-46 for more information.

Software can refer to PC as R15.

See *ARM core registers* on page B1-1143 for the system level view of these registers.

Note

In general, ARM strongly recommends using the names SP, LR and PC instead of R13, R14 and R15. However, sometimes it is simpler to use the R13-R15 names when referring to a group of registers. For example, it is simpler to refer to *Registers R8 to R15*, rather than to *Registers R8 to R12, the SP, LR and PC*. These two descriptions of the group of registers have exactly the same meaning.

A2.3.1 Writing to the PC

In ARMv7, many data-processing instructions can write to the PC. Writes to the PC are handled as follows:

- In Thumb state, the following 16-bit Thumb instruction encodings branch to the value written to the PC:
  - encoding T2 of *ADD (register, Thumb)* on page A8-310
  - encoding T1 of *MOV (register, Thumb)* on page A8-486.

  The value written to the PC is forced to be halfword-aligned by ignoring its least significant bit, treating that bit as being 0.

- The `B`, `BL`, `CBNZ`, `CBZ`, `CHKA`, `HB`, `HBL`, `HBLP`, `HBP`, `TBB`, and `TBH` instructions remain in the same instruction set state and branch to the value written to the PC.

  The definition of each of these instructions ensures that the value written to the PC is correctly aligned for the current instruction set state.

- The `BLX` (immediate) instruction switches between ARM and Thumb states and branches to the value written to the PC. Its definition ensures that the value written to the PC is correctly aligned for the new instruction set state.

- The following instructions write a value to the PC, treating that value as an interworking address to branch to, with low-order bits that determine the new instruction set state:
  - `BLX` (register), `BX`, and `BXJ`
  - `LDR` instructions with `<Rt>` equal to the PC
  - `POP` and all forms of `LDM` except `LDM` (exception return), when the register list includes the PC
  - in ARM state only, `ADC`, `ADD`, `ADR`, `AND`, `ASR` (immediate), `BIC`, `EOR`, `LSL` (immediate), `LSR` (immediate), `MOV`, `MVN`, `ORR`, `ROR` (immediate), `RRX`, `RSB`, `RSC`, `SBC`, and `SUB` instructions with `<Rd>` equal to the PC and without flag-setting specified.

  For details of how an interworking address specifies the new instruction set state and instruction address, see *Pseudocode details of operations on ARM core registers* on page A2-47.

  Note

  - The register-shifted register instructions, that are available only in the ARM instruction set and are summarized in*Data-processing (register-shifted register)* on page A5-198, cannot write to the PC.
  - The `LDR`, `POP`, and `LDM` instructions first have interworking branch behavior in ARMv5T.
  - The instructions listed as having interworking branch behavior in ARM state only first have this behavior in ARMv7.

  In the cases where later versions of the architecture introduce interworking branch behavior, the behavior in earlier architecture versions is a branch that remains in the same instruction set state. For more information, see:
  - *Interworking* on page AppxL-2501, for ARMv6
  - *Interworking* on page AppxO-2589, for ARMv5 and ARMv4.

- Some instructions are treated as exception return instructions, and write both the PC and the CPSR. For more information, including which instructions are exception return instructions, see *Exception return* on page B1-1193.

- Some instructions cause an exception, and the exception handler address is written to the PC as part of the exception entry. Similarly, in ThumbEE state, an instruction that fails its null check causes the address of the null check handler to be written to the PC, see *Null checking* on page A9-1113.

A2.3.2 Pseudocode details of operations on ARM core registers

In pseudocode, the uses of the `R[]` function are:

- reading or writing R0-R12, SP, and LR, using n == 0-12, 13, and 14 respectively
- reading the PC, using n == 15.

This function has prototypes:

```
bits(32) R[integer n]
    assert n >= 0 && n <= 15;
R[integer n] = bits(32) value
    assert n >= 0 && n <= 14;
```

Pseudocode details of ARM core register operations on page B1-1144 explains the full operation of this function.

Descriptions of ARM store instructions that store the PC value use the `PCStoreValue()` pseudocode function to specify the PC value stored by the instruction:

```
// PCStoreValue()
// ==============

bits(32) PCStoreValue()
    // This function returns the PC value. On architecture versions before ARMv7, it
    // is permitted to instead return PC+4, provided it does so consistently. It is
    // used only to describe ARM instructions, so it returns the address of the current
    // instruction plus 8 (normally) or 12 (when the alternative is permitted).
    return PC;
```

Writing an address to the PC causes either a simple branch to that address or an *interworking* branch that also selects the instruction set to execute after the branch. A simple branch is performed by the `BranchWritePC()` function:

```
// BranchWritePC()
// ===============

BranchWritePC(bits(32) address)
    if CurrentInstrSet() == InstrSet_ARM then
        if ArchVersion() < 6 && address<1:0> != '00' then UNPREDICTABLE;
        BranchTo(address<31:2>:'00');
    elsif CurrentInstrSet() == InstrSet_Jazelle then
        if JazelleAcceptsExecution() then
            BranchTo(address<31:0>);
        else
            newaddress = address;
            newaddress<1:0> = bits(2) UNKNOWN;
            BranchTo(newaddress);
    else
        BranchTo(address<31:1>:'0');
```

An interworking branch is performed by the `BXWritePC()` function:

```
// BXWritePC()
// ===========

BXWritePC(bits(32) address)
    if CurrentInstrSet() == InstrSet_ThumbEE then
        if address<0> == '1' then
            BranchTo(address<31:1>:'0');  // Remaining in ThumbEE state
        else
            UNPREDICTABLE;
    else
        if address<0> == '1' then
            SelectInstrSet(InstrSet_Thumb);
            BranchTo(address<31:1>:'0');
        elsif address<1> == '0' then
            SelectInstrSet(InstrSet_ARM);
            BranchTo(address);
        else // address<1:0> == '10'
```

```
            UNPREDICTABLE;
```

The LoadWritePC() and ALUWritePC() functions are used for two cases where the behavior was systematically modified between architecture versions:

```
// LoadWritePC()
// =============

LoadWritePC(bits(32) address)
    if ArchVersion() >= 5 then
        BXWritePC(address);
    else
        BranchWritePC(address);
// ALUWritePC()
// ============

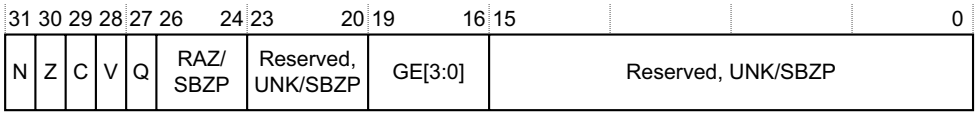
ALUWritePC(bits(32) address)
    if ArchVersion() >= 7 && CurrentInstrSet() == InstrSet_ARM then
        BXWritePC(address);
    else
        BranchWritePC(address);
```

Note

The behavior of the PC writes performed by the ALUWritePC() function is different in Debug state, where there are more UNPREDICTABLE cases. The pseudocode in this section only handles the non-debug cases. For more information, see *Behavior of Data-processing instructions that access the PC in Debug state* on page C5-2100.

A2.4 The Application Program Status Register (APSR)

Program status is reported in the 32-bit *Application Program Status Register* (APSR). The APSR bit assignments are:



The APSR bit categories are:

- Reserved bits, that are allocated to system features, or are available for future expansion. Unprivileged execution ignores writes to fields that are accessible only at PL1 or higher. However, application level software that writes to the APSR must treat reserved bits as *Do-Not-Modify* (DNM) bits. For more information about the reserved bits, see *Format of the CPSR and SPSRs* on page B1-1148.
- Bits that can be set by many instructions:
  - The Condition flags:

    N, bit[31] Negative condition flag. Set to bit[31] of the result of the instruction. If the result is regarded as a two's complement signed integer, then the processor sets N to 1 if the result is negative, and sets N to 0 if it is positive or zero.

    Z, bit[30] Zero condition flag. Set to 1 if the result of the instruction is zero, and to 0 otherwise. A result of zero often indicates an equal result from a comparison.

    C, bit[29] Carry condition flag. Set to 1 if the instruction results in a carry condition, for example an unsigned overflow on an addition.

    V, bit[28] Overflow condition flag. Set to 1 if the instruction results in an overflow condition, for example a signed overflow on an addition.
  - The Overflow or saturation flag:

    Q, bit[27] Set to 1 to indicate overflow or saturation occurred in some instructions, normally related to *digital signal processing* (DSP). For more information, see *Pseudocode details of saturation* on page A2-44.
  - The Greater than or Equal flags:

    GE[3:0], bits[19:16]

    The instructions described in *Parallel addition and subtraction instructions* on page A4-171 update these flags to indicate the results from individual bytes or halfwords of the operation. These flags can control a later `SEL` instruction. For more information, see *SEL* on page A8-602.
- Bits[26:24] are RAZ/SBZP. Therefore, software can use `MSR` instructions that write the top byte of the APSR without using a read, modify, write sequence. If it does this, it must write zeros to bits[26:24].

Instructions can test the N, Z, C, and V condition flags, combining these with the *condition code* for the instruction to determine whether the instruction must be executed. In this way, execution of the instruction is conditional on the result of a previous operation. For more information about conditional execution see *Conditional execution* on page A4-161 and *Conditional execution* on page A8-288.

In ARMv7-A and ARMv7-R, the APSR is the same register as the CPSR, but the APSR must be used only to access the N, Z, C, V, Q, and GE[3:0] bits. For more information, see *Program Status Registers (PSRs)* on page B1-1147.

A2.5 Execution state registers

The execution state registers modify the execution of instructions. They control:

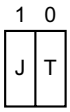
- Whether instructions are interpreted as Thumb instructions, ARM instructions, ThumbEE instructions, or Java bytecodes. For more information, see *Instruction set state register, ISETSTATE*.
- In Thumb state and ThumbEE state only, the condition codes that apply to the next one to four instructions. For more information, see *IT block state register, ITSTATE* on page A2-51.
- Whether data is interpreted as big-endian or little-endian. For more information, see *Endianness mapping register, ENDIANSTATE* on page A2-53.

In ARMv7-A and ARMv7-R, the execution state registers are part of the Current Program Status Register. For more information, see *Program Status Registers (PSRs)* on page B1-1147.

There is no direct access to the execution state registers from application level instructions, but they can be changed by side-effects of application level instructions.

A2.5.1 Instruction set state register, ISETSTATE

The instruction set state register, ISETSTATE, format is:



The J bit and the T bit determine the current *instruction set state* for the processor. Table A2-1 shows the encoding of these bits.

Table A2-1 J and T bit encoding in ISETSTATE

J	T	Instruction set state
0	0	ARM
0	1	Thumb
1	0	Jazelle
1	1	ThumbEE

ARM state The processor executes the ARM instruction set described in Chapter A5 *ARM Instruction Set Encoding*.

Thumb state The processor executes the Thumb instruction set as described in Chapter A6 *Thumb Instruction Set Encoding*.

Jazelle state The processor executes Java bytecodes as part of a *Java Virtual Machine* (JVM). For more information, see:

- *Jazelle direct bytecode execution support* on page A2-97, for application level information
- *Jazelle direct bytecode execution* on page B1-1240, for system level information.

ThumbEE state The processor executes a variation of the Thumb instruction set specifically targeted for use with dynamic compilation techniques associated with an execution environment. This can be Java or other execution environments. This feature is required in ARMv7-A, and optional in ARMv7-R. For more information, see:

- *Thumb Execution Environment* on page A2-95, for application level information
- *Thumb Execution Environment* on page B1-1239, for system level information.

Pseudocode details of ISETSTATE operations

The following pseudocode functions return the current instruction set and select a new instruction set:

```
enumeration InstrSet {InstrSet_ARM, InstrSet_Thumb, InstrSet_Jazelle, InstrSet_ThumbEE};
// CurrentInstrSet()
// =================

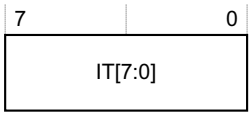
InstrSet CurrentInstrSet()
    case ISETSTATE of
        when '00'  result = InstrSet_ARM;
        when '01'  result = InstrSet_Thumb;
        when '10'  result = InstrSet_Jazelle;
        when '11'  result = InstrSet_ThumbEE;
    return result;

// SelectInstrSet()
// ================

SelectInstrSet(InstrSet iset)
    case iset of
        when InstrSet_ARM
            if CurrentInstrSet() == InstrSet_ThumbEE then
                UNPREDICTABLE;
            else
                ISETSTATE = '00';
        when InstrSet_Thumb
            ISETSTATE = '01';
        when InstrSet_Jazelle
            ISETSTATE = '10';
        when InstrSet_ThumbEE
            ISETSTATE = '11';
    return;
```

A2.5.2 IT block state register, ITSTATE

The IT block state register, ITSTATE, format is:



This field holds the If-Then execution state bits for the Thumb `IT` instruction, that applies to the *IT block* of one to four instructions that immediately follow the `IT` instruction. See *IT* on page A8-390 for a description of the `IT` instruction and the associated IT block.

ITSTATE divides into two subfields:

IT[7:5] Holds the *base condition* for the current IT block. The base condition is the top 3 bits of the condition code specified by the `<firstcond>` field of the `IT` instruction.

This subfield is `0b000` when no IT block is active.

IT[4:0] Encodes:

- The size of the IT block. This is the number of instructions that are to be conditionally executed. The size of the block is implied by the position of the least significant 1 in this field, as shown in Table A2-2 on page A2-52.
- The value of the least significant bit of the condition code for each instruction in the block.

Note

Changing the value of the least significant bit of a condition code from 0 to 1 has the effect of inverting the condition code.

This subfield is 0b00000 when no IT block is active.

When an IT instruction is executed, these bits are set according to the <firstcond> condition code in the instruction, and the *Then* and *Else* (T and E) parameters in the instruction. For more information, see *IT* on page A8-390.

When permitted, an instruction in an IT block is conditional, see *Conditional instructions* on page A4-162 and *Conditional execution* on page A8-288. The condition code used is the current value of IT[7:4]. When an instruction in an IT block completes its execution normally, ITSTATE advances to the next line of Table A2-2. A few instructions, for example BKPT, cannot be conditional and therefore are always executed, ignoring the current ITSTATE.

For details of what happens if an instruction in an IT block:

- Takes an exception see *Overview of exception entry* on page B1-1170.
- In ThumbEE state, causes a branch to a check handler, see *IT block and check handlers* on page A9-1114.

An instruction that might complete its normal execution by branching is only permitted in an IT block as the last instruction in the block. This means that normal execution of the instruction always results in ITSTATE advancing to normal execution.

Table A2-2 Effect of IT execution state bits

IT bits [a]						Note
[7:5]	[4]	[3]	[2]	[1]	[0]	
cond_base	P1	P2	P3	P4	1	Entry point for 4-instruction IT block
cond_base	P1	P2	P3	1	0	Entry point for 3-instruction IT block
cond_base	P1	P2	1	0	0	Entry point for 2-instruction IT block
cond_base	P1	1	0	0	0	Entry point for 1-instruction IT block
000	0	0	0	0	0	Normal execution, not in an IT block

a. Combinations of the IT bits not shown in this table are reserved.

On a branch or an exception return, if ITSTATE is set to a value that is not consistent with the instruction stream being branched to or returned to, then instruction execution is UNPREDICTABLE.

ITSTATE affects instruction execution only in Thumb and ThumbEE states. In ARM and Jazelle states, ITSTATE must be '00000000', otherwise the behavior is UNPREDICTABLE.

Pseudocode details of ITSTATE operations

ITSTATE advances after normal execution of an IT block instruction. This is described by the ITAdvance() pseudocode function:

```
// ITAdvance()
// ===========

ITAdvance()
    if ITSTATE<2:0> == '000' then
        ITSTATE.IT = '00000000';
    else
        ITSTATE.IT<4:0> = LSL(ITSTATE.IT<4:0>, 1);
```

The following functions test whether the current instruction is in an IT block, and whether it is the last instruction of an IT block:

```
// InITBlock()
// ===========

boolean InITBlock()
    return (ITSTATE.IT<3:0> != '0000');
```

```
// LastInITBlock()
// ===============

boolean LastInITBlock()
    return (ITSTATE.IT<3:0> == '1000');
```

A2.5.3 Endianness mapping register, ENDIANSTATE

ARMv7-A and ARMv7-R support configuration between little-endian and big-endian interpretations of data memory, as shown in Table A2-3. The endianness is controlled by ENDIANSTATE.

Table A2-3 ENDIANSTATE encoding of endianness

ENDIANSTATE	Endian mapping
0	Little-endian
1	Big-endian

The ARM and Thumb instruction sets both include an instruction to manipulate ENDIANSTATE:

`SETEND BE` Sets ENDIANSTATE to 1, for big-endian operation.

`SETEND LE` Sets ENDIANSTATE to 0, for little-endian operation.

The `SETEND` instruction is unconditional. For more information, see *SETEND* on page A8-604.

Pseudocode details of ENDIANSTATE operations

The `BigEndian()` pseudocode function tests whether big-endian memory accesses are currently selected.

```
// BigEndian()
// ===========

boolean BigEndian()
    return (ENDIANSTATE == '1');
```

A2.6 Advanced SIMD and Floating-point Extensions

Advanced SIMD and Floating-point (VFP) are two OPTIONAL extensions to ARMv7.

The Advanced SIMD Extension performs packed *Single Instruction Multiple Data* (SIMD) operations, either integer or single-precision floating-point. The Floating-point Extension performs single-precision or double-precision floating-point operations.

Both extensions permit *floating-point exceptions*, such as overflow or division by zero, to be handled without trapping. When handled in this way, a floating-point exception causes a cumulative status register bit to be set to 1 and a default result to be produced by the operation.

The ARMv7 Floating-point Extension implementation can be VFPv3 or VFPv4, see *Architecture extensions* on page A1-32. ARMv7 also defines variants of VFPv3 and VFPv4, VFPv3U and VFPv4U, that support the trapping of floating-point exceptions, see *VFPv3U and VFPv4U* on page A2-62. VFPv2 also supports the trapping of floating-point exceptions.

The Advanced SIMD implementation can be Advanced SIMDv1 or Advanced SIMDv2.

If an implementation includes both the Advanced SIMD and the Floating-point Extensions then the versions of the two extensions must align, as described in *Instruction set architecture extensions* on page A1-32.

For more information about floating-point exceptions see *Floating-point exceptions* on page A2-70.

Each version of these extensions can be implemented at a number of levels. Table A2-4 shows the permitted combinations of implementations of the two extensions.

Table A2-4 Permitted combinations of Advanced SIMD and Floating-point Extensions

Advanced SIMD	Floating-point (VFP)
Not implemented	Not implemented
Integer only	Not implemented
Integer and single-precision floating-point	Single-precision floating-point only[a]
Integer and single-precision floating-point	Single-precision and double-precision floating-point
Not implemented	Single-precision floating-point only[a]
Not implemented	Single-precision and double-precision floating-point

a. Must be able to load and store double-precision data using the bottom 16 double-precision registers, D0-D15.

The Half-precision Extension provides conversion functions in both directions between half-precision floating-point and single-precision floating-point. This extension:

- Can be implemented with any Advanced SIMDv1 or VFPv3 implementation that supports single-precision floating-point, and the Half-precision extension applies to both VFP and Advanced SIMD if they are both implemented.
- Is included in any Advanced SIMDv2 or VFPv4 implementation that supports single-precision floating-point.

For system level information about the Advanced SIMD and Floating-point Extensions see *Advanced SIMD and floating-point support* on page B1-1228.

Note

Before ARMv7, the Floating-point Extension was called the *Vector Floating-point Architecture*, and was used for vector operations. For details of these deprecated operations see Appendix K *VFP Vector Operation Support*. In ARMv7:

- ARM recommends that the Advanced SIMD Extension is used for single-precision vector floating-point operations.
- An implementation that requires support for vector operations must implement the Advanced SIMD Extension.

A2.6.1 Floating-point standards, and terminology

The ARM floating-point implementation includes support for all the required features of ANSI/IEEE Std 754-2008, *IEEE Standard for Binary Floating-Point Arithmetic*, referred to as IEEE 754-2008. However, the original implementation was based on the 1985 version of this standard, referred to as IEEE 754-1985, In this manual:

- Floating-point terminology generally uses the IEEE 754-1985 terms. This section summarizes how IEEE 754-2008 changes these terms.
- References to IEEE 754 that do not include the issue year apply to either issue of the standard.

Table A2-5 shows how the terminology in this manual differs from that used in IEEE 754-2008.

Table A2-5 Floating-point terminology

This manual, based on IEEE 754-1985[a]	IEEE 754-2008
Normalized	Normal
Denormal, or denormalized	Subnormal
Round towards Minus Infinity	roundTowardsNegative
Round towards Plus Infinity	roundTowardsPositive
Round to Zero	roundTowardZero
Round towards Nearest	roundTiesToEven
Rounding mode	Rounding-direction attribute

a. Except that *normalized number* is used in preference to *normal number*, because of the other specific uses of *normal* in this manual.

The fused multiply add operations are first defined in IEEE 754-2008, and are introduced in VFPv4 and Advanced SIMDv2. The following sections describe the instructions that perform these operations:

- *VFMA, VFMS* on page A8-892
- *VFNMA, VFNMS* on page A8-894.

All other ARMv7 floating-point operations are defined in both issues of IEEE 754.

Note

ARMv7 does not support the IEEE 754-2008 roundTiesToAway rounding mode. However, IEEE 754-compliance does not require support for this mode.

A2.6.2 Advanced SIMD and Floating-point Extension registers

From VFPv3, the Advanced SIMD and Floating-point (VFP) Extensions use the same register set. This is distinct from the ARM core register set. These registers are generally referred to as the *extension registers*.

The extension register set consists of either thirty-two or sixteen doubleword registers, as follows:

- If VFPv2 is implemented, it consists of sixteen doubleword registers.
- If VFPv3 is implemented, it consists of either thirty-two or sixteen doubleword registers. Where necessary, these two implementation options are distinguished using the terms:
  - VFPv3-D32, for an implementation with thirty-two doubleword registers
  - VFPv3-D16, for an implementation with sixteen doubleword registers.
- If VFPv4 is implemented, it consists of either thirty-two or sixteen doubleword registers. Where necessary, these two implementation options are distinguished using the terms:
  - VFPv4-D32, for an implementation with thirty-two doubleword registers
  - VFPv4-D16, for an implementation with sixteen doubleword registers.
- If Advanced SIMD is implemented, it consists of thirty-two doubleword registers.
- If Advanced SIMD and Floating-point are both implemented, Floating-point must be implemented as VFPv3-D32 or VFPv4-D32.

The Advanced SIMD and Floating-point views of the extension register set are not identical. The following sections describe these different views.

Figure A2-1 on page A2-57 shows the views of the extension register set, and the way the word, doubleword, and quadword registers overlap.

Advanced SIMD views of the extension register set

Advanced SIMD can view this register set as:

- Sixteen 128-bit quadword registers, `Q0-Q15`.
- Thirty-two 64-bit doubleword registers, `D0-D31`. This view is also available in VFPv3-D32 and VFPv4-D32.

These views can be used simultaneously. For example, a program might hold 64-bit vectors in `D0` and `D1` and a 128-bit vector in `Q1`.

Floating-point views of the extension register set

In VFPv4-D32 or VFPv3-D32, the extension register set consists of thirty-two doubleword registers, that VFP can view as:

- Thirty-two 64-bit doubleword registers, `D0-D31`. This view is also available in Advanced SIMD.
- Thirty-two 32-bit single word registers, `S0-S31`. Only half of the set is accessible in this view.

In VFPv4-D16, VFPv3-D16, and VFPv2, the extension register set consists of sixteen doubleword registers, that VFP can view as:

- Sixteen 64-bit doubleword registers, `D0-D15`.
- Thirty-two 32-bit single word registers, `S0-S31`.

In each case, the two views can be used simultaneously.

Advanced SIMD and Floating-point register mapping

Figure A2-1 shows the different views of Advanced SIMD and Floating-point register banks, and the relationship between them.

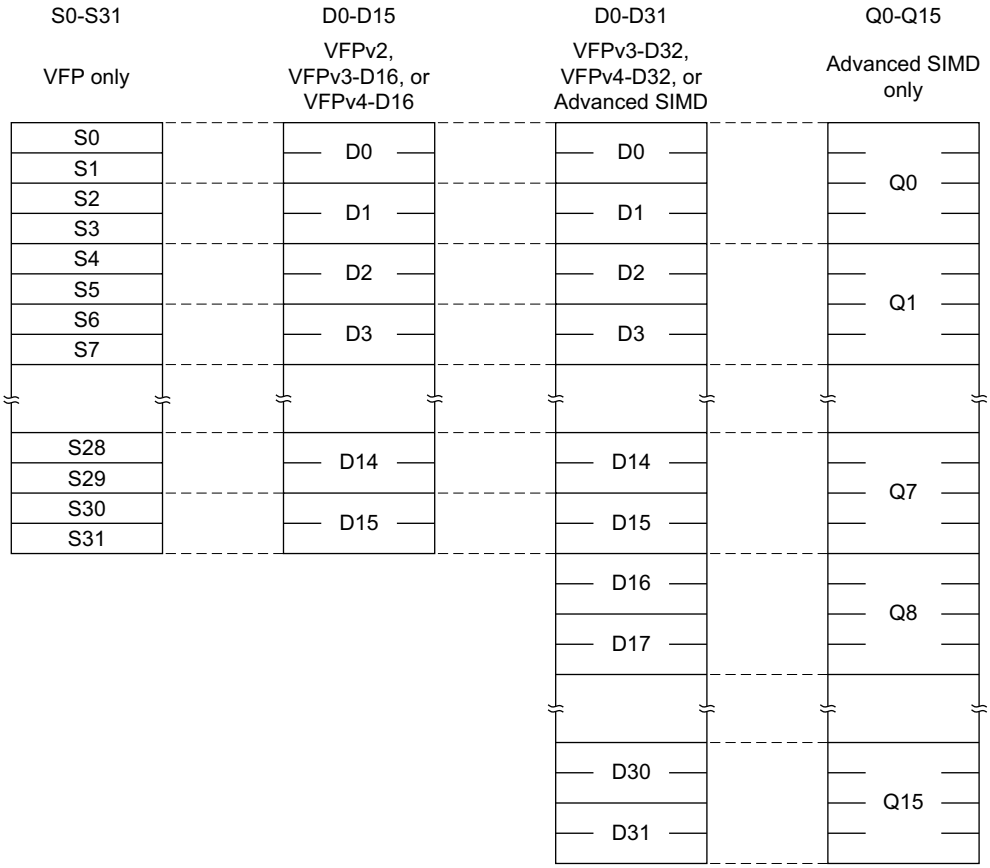


Figure A2-1 Advanced SIMD and Floating-point Extensions register set

The mapping between the registers is as follows:

- `S<2n>` maps to the least significant half of `D<n>`
- `S<2n+1>` maps to the most significant half of `D<n>`
- `D<2n>` maps to the least significant half of `Q<n>`
- `D<2n+1>` maps to the most significant half of `Q<n>`.

For example, software can access the least significant half of the elements of a vector in `Q6` by referring to `D12`, and the most significant half of the elements by referring to `D13`.

Pseudocode details of Advanced SIMD and Floating-point Extension registers

The pseudocode function `VFPSmallRegisterBank()` returns FALSE if all of the 32 registers `D0-D31` can be accessed, and TRUE if only the 16 registers `D0-D15` can be accessed:

```
boolean VFPSmallRegisterBank()
```

In more detail, `VFPSmallRegisterBank()`:

- returns TRUE for a VFPv2, VFPv3-D16, or VFPv4-D16 implementation
- for a VFPv3-D32 or VFPv4-D32 implementation:
  - returns FALSE if CPACR.D32DIS is set to 0
  - returns TRUE if CPACR.D32DIS and CPACR.ASEDIS are both set to 1
  - results in UNPREDICTABLE behavior if CPACR.D32DIS is set to 1 and CPACR.ASEDIS is set to 0.

For details of the CPACR, see either:

- *CPACR, Coprocessor Access Control Register, VMSA* on page B4-1551
- *CPACR, Coprocessor Access Control Register, PMSA* on page B6-1829.

The following functions provide the S0-S31, D0-D31, and Q0-Q15 views of the registers:

```
// The 64-bit extension register bank for Advanced SIMD and VFP.

array bits(64) _D[0..31];

// Clone the 64-bit Advanced SIMD and VFP extension register bank for use as input to
// instruction pseudocode, to avoid read-after-write for Advanced SIMD and VFP operations.

array bits(64) _Dclone[0..31];

// S[] - non-assignment form
// =========================

bits(32) S[integer n]
    assert n >= 0 && n <= 31;
    if (n MOD 2) == 0 then
        result = D[n DIV 2]<31:0>;
    else
        result = D[n DIV 2]<63:32>;
    return result;

// S[] - assignment form
// =====================

S[integer n] = bits(32) value
    assert n >= 0 && n <= 31;
    if (n MOD 2) == 0 then
        D[n DIV 2]<31:0> = value;
    else
        D[n DIV 2]<63:32> = value;
    return;

// D[] - non-assignment form
// =========================

bits(64) D[integer n]
    assert n >= 0 && n <= 31;
    if n >= 16 && VFPSmallRegisterBank() then UNDEFINED;
    return _D[n];

// D[] - assignment form
// =====================

D[integer n] = bits(64) value
    assert n >= 0 && n <= 31;
    if n >= 16 && VFPSmallRegisterBank() then UNDEFINED;
    _D[n] = value;
    return;

// Q[] - non-assignment form
// =========================

bits(128) Q[integer n]
    assert n >= 0 && n <= 15;
    return D[2*n+1]:D[2*n];
```

```
// Q[] - assignment form
// =====================

Q[integer n] = bits(128) value
    assert n >= 0 && n <= 15;
    D[2*n] = value<63:0>;
    D[2*n+1] = value<127:64>;
    return;
```

The `Din[]` function returns a Doubleword register from the `_Dclone[]` copy of the Advanced SIMD and Floating-point register bank, and the `Qin[]` function returns a Quadword register from that register bank.

Note

The `CheckAdvancedSIMDEnabled()` function copies the `_D[]` register bank to `_Dclone[]`, see *Pseudocode details of enabling the Advanced SIMD and Floating-point Extensions* on page B1-1234.

```
// Din[] - non-assignment form
// ===========================

bits(64) Din[integer n]
    assert n >= 0 && n <= 31;
    if n >= 16 && VFPSmallRegisterBank() then UNDEFINED;
    return _Dclone[n];

// Qin[] - non-assignment form
// ===========================

bits(128) Qin[integer n]
    assert n >= 0 && n <= 15;
    return Din[2*n+1]:Din[2*n];
```

A2.6.3 Data types supported by the Advanced SIMD Extension

In an implementation that includes the Advanced SIMD Extension, the Advanced SIMD instructions can operate on integer and floating-point data, and the extension defines a set of data types to represent the different data formats. Table A2-6 shows the available formats. Each instruction description specifies the data types that the instruction supports.

Table A2-6 Advanced SIMD data types

Data type specifier	Meaning
`.<size>`	Any element of `<size>` bits
`.F<size>`	Floating-point number of `<size>` bits
`.I<size>`	Signed or unsigned integer of `<size>` bits
`.P<size>`	Polynomial over {0, 1} of degree less than `<size>`
`.S<size>`	Signed integer of `<size>` bits
`.U<size>`	Unsigned integer of `<size>` bits

Polynomial arithmetic over {0, 1} on page A2-93 describes the polynomial data type.

The `.F16` data type is the half-precision data type selected by the FPSCR.AHP bit. It is supported only if an implementation includes the Half-precision extension.

The `.F32` data type is the ARM standard single-precision floating-point data type, see *Advanced SIMD and Floating-point single-precision format* on page A2-64.

The instruction definitions use a data type specifier to define the data types appropriate to the operation. Figure A2-2 shows the hierarchy of Advanced SIMD data types.

.8	.I8	.S8
		.U8
	.P8	
	-	
.16	.I16	.S16
		.U16
	.P16 †	
	.F16 ‡	
.32	.I32	.S32
		.U32
	-	
	.F32	
.64	.I64	.S64
		.U64
	-	
	-	

† Output format only. See VMULL instruction description.
‡ Supported only if the implementation includes the Half-precision Extension.

Figure A2-2 Advanced SIMD data type hierarchy

For example, a multiply instruction must distinguish between integer and floating-point data types.

An integer multiply instruction that generates a double-width (long) result must specify the input data types as signed or unsigned. However, some integer multiply instructions use modulo arithmetic, and therefore do not have to distinguish between signed and unsigned inputs.

A2.6.4 Advanced SIMD vectors

In an implementation that includes the Advanced SIMD Extension, a register can hold one or more packed elements, all of the same size and type. The combination of a register and a data type describes a vector of elements. The vector is considered to be an array of elements of the data type specified in the instruction. The number of elements in the vector is implied by the size of the data elements and the size of the register.

Vector indices are in the range 0 to (number of elements – 1). An index of 0 refers to the least significant end of the vector. Figure A2-3 on page A2-61 shows examples of Advanced SIMD vectors:

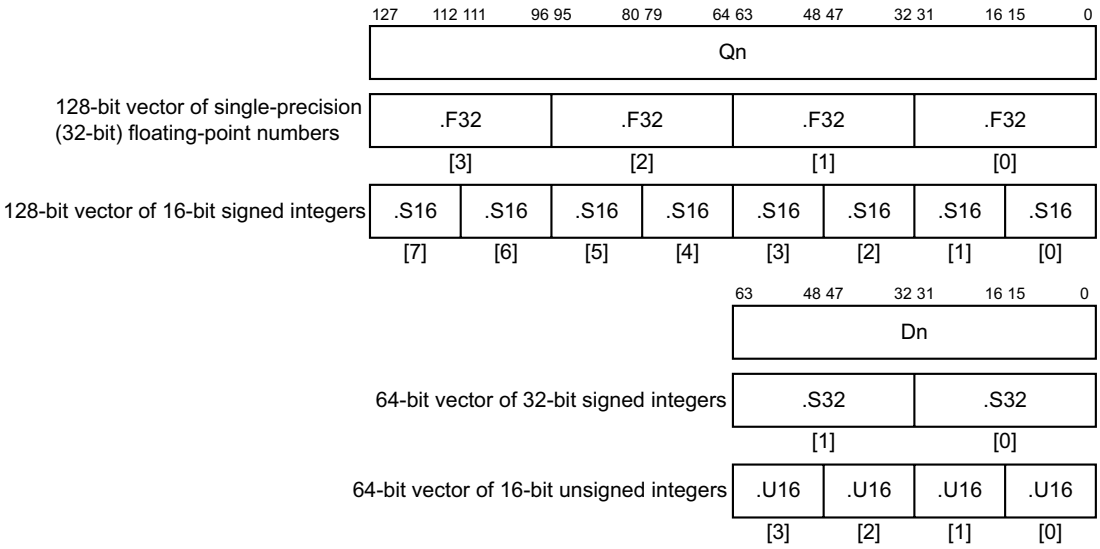

Figure A2-3 Examples of Advanced SIMD vectors

Pseudocode details of Advanced SIMD vectors

The pseudocode function `Elem[]` accesses the element of a specified index and size in a vector:

```
// Elem[] - non-assignment form
// ============================

bits(size) Elem[bits(N) vector, integer e, integer size]
    assert e >= 0 && (e+1)*size <= N;
    return vector<(e+1)*size-1:e*size>;
// Elem[] - assignment form
// ========================

Elem[bits(N) vector, integer e, integer size] = bits(size) value
    assert e >= 0 && (e+1)*size <= N;
    vector<(e+1)*size-1:e*size> = value;
    return;
```

A2.6.5 Advanced SIMD and Floating-point system registers

The Advanced SIMD and Floating-point (VFP) Extensions have a shared register space for system registers. Only one register in this space is accessible at the Application level, see either:

- *FPSCR, Floating-point Status and Control Register, VMSA* on page B4-1569
- *FPSCR, Floating-point Status and Control Register, PMSA* on page B6-1845.

Note

In this chapter, short links to the FPSCR are to the description in Chapter B4 *System Control Registers in a VMSA implementation*. The FPSCR description in Chapter B6 *System Control Registers in a PMSA implementation* is identical to this description.

Writes to the FPSCR can have side-effects on various aspects of processor operation. All of these side-effects are synchronous to the FPSCR write. This means they are guaranteed not to be visible to earlier instructions in the execution stream, and they are guaranteed to be visible to later instructions in the execution stream.

See *Advanced SIMD and Floating-point Extension system registers* on page B1-1235 for the system level view of the registers.

A2.6.6 VFPv3U and VFPv4U

The VFPv3 and VFPv4 versions of the Floating-point Extension do not support the exception trap enable bits in the FPSCR. With these versions of the Floating-point Extension, all floating-point exceptions are untrapped.

The VFPv3U variant of the VFPv3 extension, and the VFPv4U variant of the VFPv4 extension, implement exception trap enable bits in the FPSCR, and provide exception handling as described in *Floating-point support code* on page B1-1236. There is a separate trap enable bit for each of the six floating-point exceptions described in *Floating-point exceptions* on page A2-70. Except for support for this trapping mechanism:

- the VFPv3U architecture is identical to VFPv3
- the VFPv4U architecture is identical to VFPv4.

Trapped exception handling never causes the corresponding cumulative exception bit of the FPSCR to be set to 1. If this behavior is desired, the trap handler routine must use a read, modify, write sequence on the FPSCR to set the cumulative exception bit.

Both VFPv3U and VFPv4U can be implemented with either thirty-two or sixteen doubleword registers. That is:

- VFPv3U can be implemented as VFPv3U-D32, or as VFPv3U-D16
- VFPv4U can be implemented as VFPv4U-D32, or as VFPv4U-D16.

VFPv3U-D16 and VFPv4U-D16 are backwards compatible with VFPv2.

A2.7 Floating-point data types and arithmetic

The Floating-point (VFP) Extension supports single-precision (32-bit) and double-precision (64-bit) floating-point data types and arithmetic as defined by the IEEE 754 floating-point standard. It also supports the half-precision (16-bit) floating-point data type for data storage only, by supporting conversions between single-precision and half-precision data types.

ARM standard floating-point arithmetic means IEEE 754 floating-point arithmetic with the following restrictions:

- denormalized numbers are flushed to zero, see *Flush-to-zero* on page A2-68
- only default NaNs are supported, see *NaN handling and the Default NaN* on page A2-69
- the Round to Nearest rounding mode selected, by setting FPSCR.RMode to `0b00`
- untrapped exception handling selected for all floating-point exceptions, by setting FPSCR[15, 12:8] to `0b000000`.

In ARMv7 implementations, trapped floating-point exception handling is supported in the VFPv3U and VFPv4U variants of the Floating-point Extension, see *VFPv3U and VFPv4U* on page A2-62. In implementations of previous architecture versions, it is supported in VFPv2.

The Advanced SIMD Extension supports only single-precision ARM standard floating-point arithmetic.

Note

Implementations of the Floating-point Extension require *support code* to be installed in the system if trapped floating-point exception handling is required. See *Floating-point support code* on page B1-1236.

Some implementations might also require support code to support other aspects of their floating-point arithmetic. However, with the ARMv7 architecture, ARM deprecates using support code in this way.

It is IMPLEMENTATION DEFINED which aspects of Floating-point Extension floating-point arithmetic are supported in a system without support code installed.

Aspects of floating-point arithmetic that are implemented in support code are likely to run much more slowly than those that are executed in hardware.

ARM recommends that:

- To maximize the chance of getting high floating-point performance, software developers use ARM standard floating-point arithmetic.
- Software developers check whether their systems have support code installed, and if not, observe the IMPLEMENTATION DEFINED restrictions on what operations their Floating-point Extension implementation can handle without support code.
- Floating-point Extension implementation developers implement at least ARM standard floating-point arithmetic in hardware, so that it can be executed without any need for support code.

A2.7.1 ARM standard floating-point input and output values

ARM standard floating-point arithmetic supports the following input formats defined by the IEEE 754 floating-point standard:

- Zeros.
- Normalized numbers.
- Denormalized numbers are flushed to 0 before floating-point operations, see *Flush-to-zero* on page A2-68.
- NaNs.
- Infinities.

ARM standard floating-point arithmetic supports the Round to Nearest rounding mode defined by the IEEE 754 standard.

ARM standard floating-point arithmetic supports the following output result formats defined by the IEEE 754 standard:

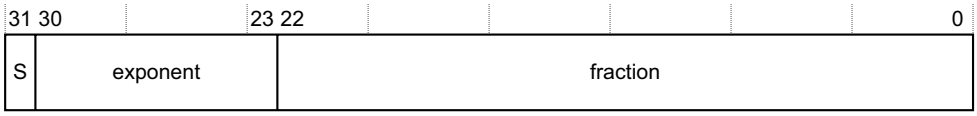
- Zeros.
- Normalized numbers.
- Results that are less than the minimum normalized number are flushed to zero, see *Flush-to-zero* on page A2-68.
- NaNs produced in floating-point operations are always the default NaN, see *NaN handling and the Default NaN* on page A2-69.
- Infinities.

A2.7.2 Advanced SIMD and Floating-point single-precision format

The single-precision floating-point format used by the Advanced SIMD and Floating-point Extensions is as defined by the IEEE 754 standard.

This description includes ARM-specific details that are left open by the standard. It is only intended as an introduction to the formats and to the values they can contain. For full details, especially of the handling of infinities, NaNs and signed zeros, see the IEEE 754 standard.

A single-precision value is a 32-bit word with the format:



The interpretation of the format depends on the value of the exponent field, bits[30:23]:

0 < exponent < `0xFF`

The value is a *normalized number* and is equal to:

$(-1)^S \times 2^{(\text{exponent} - 127)} \times (1.\text{fraction})$

The minimum positive normalized number is 2^{-126}, or approximately 1.175×10^{-38}.

The maximum positive normalized number is $(2 - 2^{-23}) \times 2^{127}$, or approximately 3.403×10^{38}.

exponent == 0

The value is either a zero or a *denormalized number*, depending on the fraction bits:

fraction == 0

The value is a zero. There are two distinct zeros:

+0 When S==0.

–0 When S==1.

These usually behave identically. In particular, the result is *equal* if +0 and –0 are compared as floating-point numbers. However, they yield different results in some circumstances. For example, the sign of the infinity produced as the result of dividing by zero depends on the sign of the zero. The two zeros can be distinguished from each other by performing an integer comparison of the two words.

fraction != 0

The value is a denormalized number and is equal to:

$(-1)^S \times 2^{-126} \times (0.\text{fraction})$

The minimum positive denormalized number is 2^{-149}, or approximately 1.401×10^{-45}.

Denormalized numbers are always flushed to zero in the Advanced SIMD Extension. They are optionally flushed to zero in the Floating-point Extension. For details see *Flush-to-zero* on page A2-68.

exponent == `0xFF`

The value is either an *infinity* or a *Not a Number* (NaN), depending on the fraction bits:

fraction == 0

The value is an infinity. There are two distinct infinities:

+infinity When S==0. This represents all positive numbers that are too big to be represented accurately as a normalized number.

-infinity When S==1. This represents all negative numbers with an absolute value that is too big to be represented accurately as a normalized number.

fraction != 0

The value is a NaN, and is either a *quiet NaN* or a *signaling NaN*.

In the Floating-point Extension, the two types of NaN are distinguished on the basis of their most significant fraction bit, bit[22]:

bit[22] == 0

The NaN is a signaling NaN. The sign bit can take any value, and the remaining fraction bits can take any value except all zeros.

bit[22] == 1

The NaN is a quiet NaN. The sign bit and remaining fraction bits can take any value.

For details of the *default NaN* see *NaN handling and the Default NaN* on page A2-69.

Note

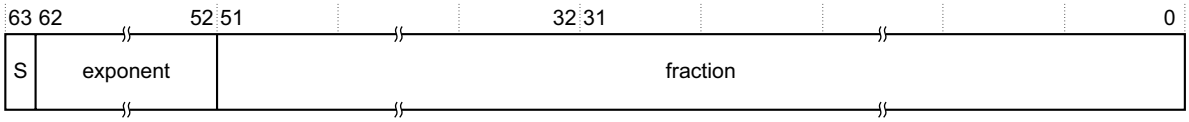
NaNs with different sign or fraction bits are distinct NaNs, but this does not mean software can use floating-point comparison instructions to distinguish them. This is because the IEEE 754 standard specifies that a NaN compares as *unordered* with everything, including itself.

A2.7.3 Floating-point double-precision format

The double-precision floating-point format used by the Floating-point Extension is as defined by the IEEE 754 standard.

This description includes Floating-point Extension-specific details that are left open by the standard. It is only intended as an introduction to the formats and to the values they can contain. For full details, especially of the handling of infinities, NaNs and signed zeros, see the IEEE 754 standard.

A double-precision value is a 64-bit doubleword, with the format:



Double-precision values represent numbers, infinities and NaNs in a similar way to single-precision values, with the interpretation of the format depending on the value of the exponent:

0 < exponent < `0x7FF`

The value is a normalized number and is equal to:

$(-1)^S \times 2^{(\text{exponent}-1023)} \times (1.\text{fraction})$

The minimum positive normalized number is 2^{-1022}, or approximately 2.225×10^{-308}.

The maximum positive normalized number is $(2 - 2^{-52}) \times 2^{1023}$, or approximately 1.798×10^{308}.

exponent == 0

The value is either a zero or a denormalized number, depending on the fraction bits:

fraction == 0

The value is a zero. There are two distinct zeros that behave analogously to the two single-precision zeros:

+0 when S==0

–0 when S==1.

fraction != 0

The value is a denormalized number and is equal to:

$(-1)^S \times 2^{-1022} \times (0.\text{fraction})$

The minimum positive denormalized number is 2^{-1074}, or approximately 4.941×10^{-324}.

Optionally, denormalized numbers are flushed to zero in the Floating-point Extension. For details see *Flush-to-zero* on page A2-68.

exponent == `0x7FF`

The value is either an infinity or a NaN, depending on the fraction bits:

fraction == 0

the value is an infinity. As for single-precision, there are two infinities:

+infinity When S==0.

-infinity When S==1.

fraction != 0

The value is a NaN, and is either a *quiet NaN* or a *signaling NaN*.

In the Floating-point Extension, the two types of NaN are distinguished on the basis of their most significant fraction bit, bit[19] of the most significant word:

bit[19] == 0

The NaN is a signaling NaN. The sign bit can take any value, and the remaining fraction bits can take any value except all zeros.

bit[19] == 1

The NaN is a quiet NaN. The sign bit and the remaining fraction bits can take any value.

For details of the *default NaN* see *NaN handling and the Default NaN* on page A2-69.

Note

NaNs with different sign or fraction bits are distinct NaNs, but this does not mean software can use floating-point comparison instructions to distinguish them. This is because the IEEE 754 standard specifies that a NaN compares as *unordered* with everything, including itself.

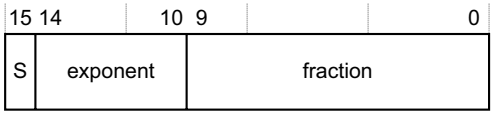
A2.7.4 Advanced SIMD and Floating-point half-precision formats

The Half-precision Extension to the Advanced SIMD and Floating-point Extensions uses two half-precision floating-point formats:

- IEEE half-precision, as described in the IEEE 754-2008 standard
- Alternative half-precision.

The description of IEEE half-precision includes ARM-specific details that are left open by the standard, and is only an introduction to the formats and to the values they can contain. For more information, especially on the handling of infinities, NaNs and signed zeros, see the IEEE 754 standard.

For both half-precision floating-point formats, the layout of the 16-bit number is the same. The format is:



The interpretation of the format depends on the value of the exponent field, bits[14:10] and on which half-precision format is being used.

0 < exponent < `0x1F`

The value is a normalized number and is equal to:

$(-1)^S \times 2^{(exponent-15)} \times (1.fraction)$

The minimum positive normalized number is 2^{-14}, or approximately 6.104×10^{-5}.

The maximum positive normalized number is $(2 - 2^{-10}) \times 2^{15}$, or 65504.

Larger normalized numbers can be expressed using the alternative format when the exponent == `0x1F`.

exponent == 0

The value is either a zero or a denormalized number, depending on the fraction bits:

fraction == 0

The value is a zero. There are two distinct zeros:

+0 when S==0

–0 when S==1.

fraction != 0

The value is a denormalized number and is equal to:

$(-1)^S \times 2^{-14} \times (0.fraction)$

The minimum positive denormalized number is 2^{-24}, or approximately 5.960×10^{-8}.

exponent == `0x1F`

The value depends on which half-precision format is being used:

IEEE half-precision

The value is either an infinity or a Not a Number (NaN), depending on the fraction bits:

fraction == 0

The value is an infinity. There are two distinct infinities:

+infinity When S==0. This represents all positive numbers that are too big to be represented accurately as a normalized number.

-infinity When S==1. This represents all negative numbers with an absolute value that is too big to be represented accurately as a normalized number.

fraction != 0

The value is a NaN, and is either a quiet NaN or a signaling NaN. The two types of NaN are distinguished by their most significant fraction bit, bit[9]:

bit[9] == 0 The NaN is a signaling NaN. The sign bit can take any value, and the remaining fraction bits can take any value except all zeros.

bit[9] == 1 The NaN is a quiet NaN. The sign bit and remaining fraction bits can take any value.

Alternative half-precision

The value is a normalized number and is equal to:

$-1^S \times 2^{16} \times (1.fraction)$

The maximum positive normalized number is $(2\text{-}2^{-10}) \times 2^{16}$ or 131008.

A2.7.5 Flush-to-zero

The performance of floating-point implementations can be significantly reduced when performing calculations involving denormalized numbers and Underflow exceptions. In particular this occurs for implementations that only handle normalized numbers and zeros in hardware, and invoke support code to handle any other types of value. For an algorithm where a significant number of the operands and intermediate results are denormalized numbers, this can result in a considerable loss of performance.

In many of these algorithms, this performance can be recovered, without significantly affecting the accuracy of the final result, by replacing the denormalized operands and intermediate results with zeros. To permit this optimization, Floating-point Extension implementations have a special processing mode called *Flush-to-zero* mode. Advanced SIMD implementations always use Flush-to-zero mode.

Behavior in Flush-to-zero mode differs from normal IEEE 754 arithmetic in the following ways:

- All inputs to floating-point operations that are double-precision denormalized numbers or single-precision denormalized numbers are treated as though they were zero. This causes an Input Denormal exception, but does not cause an Inexact exception. The Input Denormal exception occurs only in Flush-to-zero mode.

  Note

  Combinations of exceptions on page A2-71 defines the floating-point operations.

  The FPSCR contains a cumulative exception bit FPSCR.IDC and trap enable bit FPSCR.IDE corresponding to the Input Denormal exception.

  The occurrence of all exceptions except Input Denormal is determined using the input values after flush-to-zero processing has occurred.

- The result of a floating-point operation is flushed to zero if the result of the operation before rounding satisfies the condition:

  $0 < \texttt{Abs(result)} <$ MinNorm, where:

  — MinNorm is 2^{-126} for single-precision

  — MinNorm is 2^{-1022} for double-precision.

  This causes the FPSCR.UFC bit to be set to 1, and prevents any Inexact exception from occurring for the operation.

  Underflow exceptions occur only when a result is flushed to zero.

  In a VFPv2, VFPv3U, or VFPv4U implementation Underflow exceptions that occur in Flush-to-zero mode are always treated as untrapped, even when the Underflow trap enable bit, FPSCR.UFE, is set to 1.

- An Inexact exception does not occur if the result is flushed to zero, even though the final result of zero is not equivalent to the value that would be produced if the operation were performed with unbounded precision and exponent range.

When an input or a result is flushed to zero the value of the sign bit of the zero is determined as follows:

- In VFPv4, VFPv4U, VFPv3, or VFPv3U, it is preserved. That is, the sign bit of the zero matches the sign bit of the input or result that is being flushed to zero.
- In VFPv2, it is IMPLEMENTATION DEFINED whether it is preserved or always positive. The same choice must be made for all cases of flushing an input or result to zero.

Flush-to-zero mode has no effect on half-precision numbers that are inputs to floating-point operations, or results from floating-point operations.

Note

Flush-to-zero mode is incompatible with the IEEE 754 standard, and must not be used when IEEE 754 compatibility is a requirement. Flush-to-zero mode must be used with care. Although it can improve performance on some algorithms, there are significant limitations on its use. These are application dependent:

- On many algorithms, it has no noticeable effect, because the algorithm does not normally use denormalized numbers.
- On other algorithms, it can cause exceptions to occur or seriously reduce the accuracy of the results of the algorithm.

A2.7.6 NaN handling and the Default NaN

The IEEE 754 standard specifies that:

- an operation that produces an Invalid Operation floating-point exception generates a quiet NaN as its result if that exception is untrapped
- an operation involving a quiet NaN operand, but not a signaling NaN operand, returns an input NaN as its result.

The Floating-point Extension behavior when Default NaN mode is disabled adheres to this, with the following additions:

- If an untrapped Invalid Operation floating-point exception is produced, the quiet NaN result is derived from:
  - the first signaling NaN operand, if the exception was produced because at least one of the operands is a signaling NaN
  - otherwise, the default NaN
- If an untrapped Invalid Operation floating-point exception is not produced, but at least one of the operands is a quiet NaN, the result is derived from the first quiet NaN operand.

Depending on the operation, the exact value of a derived quiet NaN result may differ in both sign and number of fraction bits from its source.For a quiet NaN result derived from signaling NaN operand, the most-significant fraction bit is set to 1.

Note

- In these descriptions, *first operand* relates to the left-to-right ordering of the arguments to the pseudocode function that describes the operation.
- The IEEE 754 standard specifies that the sign bit of a NaN has no significance.

The Floating-point Extension behavior when Default NaN mode is enabled, and the Advanced SIMD behavior in all circumstances, is that the Default NaN is the result of all floating-point operations that either:

- generate untrapped Invalid Operation floating-point exceptions
- have one or more quiet NaN inputs, but no signaling NaN inputs.

Table A2-7 on page A2-70 shows the format of the default NaN for ARM floating-point processors.

Default NaN mode is selected for the Floating-point Extension by setting the FPSCR.DN bit to 1.

Other aspects of the functionality of the Invalid Operation exception are not affected by Default NaN mode. These are that:

- If untrapped, it causes the FPSCR.IOC bit be set to 1.
- If trapped, it causes a user trap handler to be invoked. This is only possible in VFPv2, VFPv3U, and VFPv4U.

Table A2-7 Default NaN encoding

	Half-precision, IEEE Format	Single-precision	Double-precision
Sign bit	0	0[a]	0[a]
Exponent	0x1F	0xFF	0x7FF
Fraction	Bit[9] == 1, bits[8:0] == 0	bit[22] == 1, bits[21:0] == 0	bit[51] == 1, bits[50:0] == 0

a. In VFPv2, the sign bit of the Default NaN is UNKNOWN.

A2.7.7 Floating-point exceptions

The Advanced SIMD and Floating-point Extensions record the following floating-point exceptions in the FPSCR cumulative bits:

FPSCR.IOC Invalid Operation. The bit is set to 1 if the result of an operation has no mathematical value or cannot be represented. Cases include, for example:

- (infinity) × 0
- (+infinity) + (–infinity).

These tests are made after flush-to-zero processing. For example, if flush-to-zero mode is selected, multiplying a denormalized number and an infinity is treated as (0 × infinity), and causes an Invalid Operation floating-point exception.

IOC is also set on any floating-point operation with one or more signaling NaNs as operands, except for negation and absolute value, as described in *Floating-point negation and absolute value* on page A2-75.

FPSCR.DZC Division by Zero. The bit is set to 1 if a divide operation has a zero divisor and a dividend that is not zero, an infinity or a NaN. These tests are made after flush-to-zero processing, so if flush-to-zero processing is selected, a denormalized dividend is treated as zero and prevents Division by Zero from occurring, and a denormalized divisor is treated as zero and causes Division by Zero to occur if the dividend is a normalized number.

For the reciprocal and reciprocal square root estimate functions the dividend is assumed to be +1.0. This means that a zero or denormalized operand to these functions sets the DZC bit.

FPSCR.OFC Overflow. The bit is set to 1 if the absolute value of the result of an operation, produced after rounding, is greater than the maximum positive normalized number for the destination precision.

FPSCR.UFC Underflow. The bit is set to 1 if the absolute value of the result of an operation, produced before rounding, is less than the minimum positive normalized number for the destination precision, and the rounded result is inexact.

The criteria for the Underflow exception to occur are different in Flush-to-zero mode. For details, see *Flush-to-zero* on page A2-68.

FPSCR.IXC Inexact. The bit is set to 1 if the result of an operation is not equivalent to the value that would be produced if the operation were performed with unbounded precision and exponent range.

The criteria for the Inexact exception to occur are different in Flush-to-zero mode. For details, see *Flush-to-zero* on page A2-68.

FPSCR.IDC Input Denormal. The bit is set to 1 if a denormalized input operand is replaced in the computation by a zero, as described in *Flush-to-zero* on page A2-68.

With the Advanced SIMD Extension and the VFPv3 or VFPv4 versions of the Floating-point Extension these are non-trapping exceptions and the data-processing instructions do not generate any trapped exceptions.

With the VFPv2, VFPv3U, and VFPv4U versions of the Floating-point Extension:

- These exceptions can be trapped, by setting trap enable bits in the FPSCR, see *VFPv3U and VFPv4U* on page A2-62. The way in which trapped floating-point exceptions are delivered to user software is IMPLEMENTATION DEFINED. However, ARM recommends use of the VFP subarchitecture defined in Appendix F *Common VFP Subarchitecture Specification*.
- The definition of the Underflow exception is different in the trapped and cummulative exception cases. In the trapped case, meaning for VFPv2, VFPv3U, or VFPv4U, the definition is:
  - the trapped Underflow exception occurs if the absolute value of the result of an operation, produced before rounding, is less than the minimum positive normalized number for the destination precision, regardless of whether the rounded result is inexact.
- As with cumulative exceptions, higher priority trapped exceptions can prevent lower priority exceptions from occurring, as described in *Combinations of exceptions*.

Table A2-8 shows the results of untrapped floating-point exceptions:

Table A2-8 Results of untrapped floating-point exceptions

Exception type	Default result for positive sign	Default result for negative sign
IOC, Invalid Operation	Quiet NaN	Quiet NaN
DZC, Division by Zero	+infinity	-infinity
OFC, Overflow	RN, RP: +infinity RM, RZ: +MaxNorm	RN, RM: -infinity RP, RZ: -MaxNorm
UFC, Underflow	Normal rounded result	Normal rounded result
IXC, Inexact	Normal rounded result	Normal rounded result
IDC, Input Denormal	Normal rounded result	Normal rounded result

In Table A2-8:

MaxNorm The maximum normalized number of the destination precision.
RM Round towards Minus Infinity mode, as defined in the IEEE 754 standard.
RN Round to Nearest mode, as defined in the IEEE 754 standard.
RP Round towards Plus Infinity mode, as defined in the IEEE 754 standard.
RZ Round towards Zero mode, as defined in the IEEE 754 standard.

- For Invalid Operation exceptions, for details of which quiet NaN is produced as the default result see *NaN handling and the Default NaN* on page A2-69.
- For Division by Zero exceptions, the sign bit of the default result is determined normally for a division. This means it is the exclusive OR of the sign bits of the two operands.
- For Overflow exceptions, the sign bit of the default result is determined normally for the overflowing operation.

Combinations of exceptions

The following pseudocode functions perform *floating-point operations*:

```
FixedToFP()
FPAdd()
FPCompare()
FPCompareEQ()
FPCompareGE()
FPCompareGT()
FPDiv()
```

```
FPDoubleToSingle()
FPHalfToSingle()
FPMax()
FPMin()
FPMul()
FPMulAdd()
FPRecipEstimate()
FPRecipStep()
FPRSqrtEstimate()
FPRSqrtStep()
FPSingleToDouble()
FPSingleToHalf()
FPSqrt()
FPSub()
FPToFixed()
```

All of these operations can generate floating-point exceptions.

Note

`FPAbs()` and `FPNeg()` are not classified as *floating-point operations* because:

- they cannot generate floating-point exceptions
- the floating-point operation behavior described in the following sections does not apply to them:
  - — *Flush-to-zero* on page A2-68
  - — *NaN handling and the Default NaN* on page A2-69.

More than one exception can occur on the same operation. The only combinations of exceptions that can occur are:

- Overflow with Inexact
- Underflow with Inexact
- Input Denormal with other exceptions.

When none of the exceptions caused by an operation are trapped, any exception that occurs causes the associated cumulative bit in the FPSCR to be set.

When one or more exceptions caused by an operation are trapped, the behavior of the instruction depends on the priority of the exceptions. The Inexact exception is treated as lowest priority, and Input Denormal as highest priority:

- If the higher priority exception is trapped, its trap handler is called. It is IMPLEMENTATION DEFINED whether the parameters to the trap handler include information about the lower priority exception. Apart from this, the lower priority exception is ignored in this case.
- If the higher priority exception is untrapped, its cumulative bit is set to 1 and its default result is evaluated. Then the lower priority exception is handled normally, using this default result.

Some floating-point instructions specify more than one floating-point operation, as indicated by the pseudocode descriptions of the instruction. In such cases, an exception on one operation is treated as higher priority than an exception on another operation if the occurrence of the second exception depends on the result of the first operation. Otherwise, it is UNPREDICTABLE which exception is treated as higher priority.

For example, a `VMLA.F32` instruction specifies a floating-point multiplication followed by a floating-point addition. The addition can generate Overflow, Underflow and Inexact exceptions, all of which depend on both operands to the addition and so are treated as lower priority than any exception on the multiplication. The same applies to Invalid Operation exceptions on the addition caused by adding opposite-signed infinities. The addition can also generate an Input Denormal exception, caused by the addend being a denormalized number while in Flush-to-zero mode. It is UNPREDICTABLE which of an Input Denormal exception on the addition and an exception on the multiplication is treated as higher priority, because the occurrence of the Input Denormal exception does not depend on the result of the multiplication. The same applies to an Invalid Operation exception on the addition caused by the addend being a signaling NaN.

Note

- The VFMA instruction performs a vector addition and a vector multiplication as a single operation. The VFMS instruction performs a vector subtraction and a vector multiplication as a single operation.
- Like other details of Floating-point instruction execution, these rules about exception handling apply to the overall results produced by an instruction when the system uses a combination of hardware and support code to implement it. See *Floating-point support code* on page B1-1236 for more information.

  These principles also apply to the multiple floating-point operations generated by Floating-point instructions in the deprecated VFP vector mode of operation. For details of this mode of operation see Appendix K *VFP Vector Operation Support*.

A2.7.8 Pseudocode details of floating-point operations

The following subsections contain pseudocode definitions of the floating-point functionality supported by the ARMv7 architecture:

- *Generation of specific floating-point values*
- *Floating-point negation and absolute value* on page A2-75
- *Floating-point value unpacking* on page A2-75
- *Floating-point exception and NaN handling* on page A2-76
- *Floating-point rounding* on page A2-78
- *Selection of ARM standard floating-point arithmetic* on page A2-79
- *Floating-point comparisons* on page A2-80
- *Floating-point maximum and minimum* on page A2-81
- *Floating-point addition and subtraction* on page A2-82
- *Floating-point multiplication and division* on page A2-83
- *Floating-point fused multiply-add* on page A2-84
- *Floating-point reciprocal estimate and step* on page A2-85
- *Floating-point square root* on page A2-87
- *Floating-point reciprocal square root estimate and step* on page A2-87
- *Floating-point conversions* on page A2-90.

Generation of specific floating-point values

The following pseudocode functions generate specific floating-point values. The sign argument of FPInfinity(), FPMaxNormal(), and FPZero() is '0' for the positive version and '1' for the negative version.

```
// FPZero()
// ========

bits(N) FPZero(bit sign, integer N)
    assert N IN {16,32,64};
    if N == 16 then
        return sign : '00000 0000000000';
    elsif N == 32 then
        return sign : '00000000 00000000000000000000000';
    else
        return sign : '00000000000 0000000000000000000000000000000000000000000000000000';
// FPTwo()
// =======

bits(N) FPTwo(integer N)
    assert N IN {32,64};
    if N == 32 then
        return '0 10000000 00000000000000000000000';
    else
        return '0 10000000000 0000000000000000000000000000000000000000000000000000';
```

```
// FPThree()
// =========

bits(N) FPThree(integer N)
    assert N IN {32,64};
    if N == 32 then
        return '0 10000000 10000000000000000000000';
    else
        return '0 10000000000 1000000000000000000000000000000000000000000000000000';

// FPMaxNormal()
// =============

bits(N) FPMaxNormal(bit sign, integer N)
    assert N IN {16,32,64};
    if N == 16 then
        return sign : '11110 1111111111';
    elsif N == 32 then
        return sign : '11111110 11111111111111111111111';
    else
        return sign : '11111111110 1111111111111111111111111111111111111111111111111111';

// FPInfinity()
// ============

bits(N) FPInfinity(bit sign, integer N)
    assert N IN {16,32,64};
    if N == 16 then
        return sign : '11111 0000000000';
    elsif N == 32 then
        return sign : '11111111 00000000000000000000000';
    else
        return sign : '11111111111 0000000000000000000000000000000000000000000000000000';

// FPDefaultNaN()
// ==============

bits(N) FPDefaultNaN(integer N)
    assert N IN {16,32,64};
    if N == 16 then
        return '0 11111 1000000000';
    elsif N == 32 then
        return '0 11111111 10000000000000000000000';
    else
        return '0 11111111111 1000000000000000000000000000000000000000000000000000';
```

Note

This definition of `FPDefaultNaN()` applies to VFPv4, VFPv4U, VFPv3, and VFPv3U implementations. For VFPv2, the sign bit of the result is a single-bit UNKNOWN value, instead of 0.

Floating-point negation and absolute value

The floating-point negation and absolute value operations only affect the sign bit. They do not treat NaN operands specially, nor denormalized number operands when flush-to-zero is selected.

```
// FPNeg()
// =======

bits(N) FPNeg(bits(N) operand)
    assert N IN {32,64};
    return NOT(operand<N-1>) : operand<N-2:0>;

// FPAbs()
// =======

bits(N) FPAbs(bits(N) operand)
    assert N IN {32,64};
    return '0' : operand<N-2:0>;
```

Floating-point value unpacking

The `FPUnpack()` function determines the type and numerical value of a floating-point number. It also does flush-to-zero processing on input operands.

```
enumeration FPType {FPType_Nonzero, FPType_Zero, FPType_Infinity, FPType_QNaN, FPType_SNaN};
// FPUnpack()
// ==========
//
// Unpack a floating-point number into its type, sign bit and the real number
// that it represents. The real number result has the correct sign for numbers
// and infinities, is very large in magnitude for infinities, and is 0.0 for
// NaNs. (These values are chosen to simplify the description of comparisons
// and conversions.)
//
// The 'fpscr_val' argument supplies FPSCR control bits. Status information is
// updated directly in the FPSCR where appropriate.

(FPType, bit, real) FPUnpack(bits(N) fpval, bits(32) fpscr_val)
    assert N IN {16,32,64};

    if N == 16 then
        sign = fpval<15>;
        exp = fpval<14:10>;
        frac = fpval<9:0>;
        if IsZero(exp) then
            // Produce zero if value is zero
            if IsZero(frac) then
                type = FPType_Zero;  value = 0.0;
            else
                type = FPType_Nonzero;  value = 2^-14 * (UInt(frac) * 2^-10);
        elsif IsOnes(exp) && fpscr_val<26> == '0' then  // Infinity or NaN in IEEE format
            if IsZero(frac) then
                type = FPType_Infinity;  value = 2^1000000;
            else
                type = if frac<9> == '1' then FPType_QNaN else FPType_SNaN;
                value = 0.0;
        else
            type = FPType_Nonzero;  value = 2^(UInt(exp)-15) * (1.0 + UInt(frac) * 2^-10);

    elsif N == 32 then

        sign = fpval<31>;
        exp  = fpval<30:23>;
        frac = fpval<22:0>;
        if IsZero(exp) then
            // Produce zero if value is zero or flush-to-zero is selected.
```

```
            if IsZero(frac) || fpscr_val<24> == '1' then
                type = FPType_Zero;  value = 0.0;
                if !IsZero(frac) then  // Denormalized input flushed to zero

    if sign == '1' then value = -value;
    return (type, sign, value);
```

Floating-point exception and NaN handling

The `FPProcessException()` procedure checks whether a floating-point exception is trapped, and handles it accordingly:

```
enumeration FPExc {FPExc_InvalidOp, FPExc_DivideByZero, FPExc_Overflow,
                   FPExc_Underflow, FPExc_Inexact, FPExc_InputDenorm};
// FPProcessException()
// ====================
//
// The 'fpscr_val' argument supplies FPSCR control bits. Status information is
// updated directly in the FPSCR where appropriate.

FPProcessException(FPExc exception, bits(32) fpscr_val)
    // Get appropriate FPSCR bit numbers
    case exception of
        when FPExc_InvalidOp     enable = 8;   cumul = 0;
        when FPExc_DivideByZero  enable = 9;   cumul = 1;
        when FPExc_Overflow      enable = 10;  cumul = 2;
        when FPExc_Underflow     enable = 11;  cumul = 3;
        when FPExc_Inexact       enable = 12;  cumul = 4;
        when FPExc_InputDenorm   enable = 15;  cumul = 7;
    if fpscr_val<enable> then
        IMPLEMENTATION_DEFINED floating-point trap handling;
    else
        FPSCR<cumul> = '1';
```

```
    return;
```

The FPProcessNaN() function processes a NaN operand, producing the correct result value and generating an Invalid Operation exception if necessary:

```
// FPProcessNaN()
// ==============
//
// The 'fpscr_val' argument supplies FPSCR control bits. Status information is
// updated directly in the FPSCR where appropriate.

bits(N) FPProcessNaN(FPType type, bits(N) operand, bits(32) fpscr_val)
    assert N IN {32,64};
    topfrac = if N == 32 then 22 else 51;
    result = operand;
    if type == FPType_SNaN then
        result<topfrac> = '1';
        FPProcessException(FPExc_InvalidOp, fpscr_val);
    if fpscr_val<25> == '1' then  // DefaultNaN requested
        result = FPDefaultNaN(N);
    return result;
```

The FPProcessNaNs() function performs the standard NaN processing for a two-operand operation:

```
// FPProcessNaNs()
// ===============
//
// The boolean part of the return value says whether a NaN has been found and
// processed. The bits(N) part is only relevant if it has and supplies the
// result of the operation.
//
// The 'fpscr_val' argument supplies FPSCR control bits. Status information is
// updated directly in the FPSCR where appropriate.

(boolean, bits(N)) FPProcessNaNs(FPType type1, FPType type2,
                                 bits(N) op1, bits(N) op2,
                                 bits(32) fpscr_val)
    assert N IN {32,64};
    if type1 == FPType_SNaN then
        done = TRUE;  result = FPProcessNaN(type1, op1, fpscr_val);
    elsif type2 == FPType_SNaN then
        done = TRUE;  result = FPProcessNaN(type2, op2, fpscr_val);
    elsif type1 == FPType_QNaN then
        done = TRUE;  result = FPProcessNaN(type1, op1, fpscr_val);
    elsif type2 == FPType_QNaN then
        done = TRUE;  result = FPProcessNaN(type2, op2, fpscr_val);
    else
        done = FALSE;  result = Zeros(N);  // 'Don't care' result
    return (done, result);
```

The FPProcessNaNs3() function performs the standard NaN processing for a three-operand operation:

```
// FPProcessNaNs3()
// ================
//
// The boolean part of the return value says whether a NaN has been found and
// processed. The bits(N) part is only relevant if it has and supplies the
// result of the operation.
//
// The 'fpscr_val' argument supplies FPSCR control bits. Status information is
// updated directly in the FPSCR where appropriate.

(boolean, bits(N)) FPProcessNaNs3(FPType type1, FPType type2, FPType type3,
                                  bits(N) op1, bits(N) op2, bits(N) op3,
                                  bits(32) fpscr_val)
    assert N IN {32,64};
    if type1 == FPType_SNaN then
        done = TRUE;  result = FPProcessNaN(type1, op1, fpscr_val);
    elsif type2 == FPType_SNaN then
```

```
        done = TRUE;  result = FPProcessNaN(type2, op2, fpscr_val);
    elsif type3 == FPType_SNaN then
        done = TRUE;  result = FPProcessNaN(type3, op3, fpscr_val);
    elsif type1 == FPType_QNaN then
        done = TRUE;  result = FPProcessNaN(type1, op1, fpscr_val);
    elsif type2 == FPType_QNaN then
        done = TRUE;  result = FPProcessNaN(type2, op2, fpscr_val);
    elsif type3 == FPType_QNaN then
        done = TRUE;  result = FPProcessNaN(type3, op3, fpscr_val);
    else
        done = FALSE;  result = Zeros(N);  // 'Don't care' result
    return (done, result);
```

Floating-point rounding

The `FPRound()` function rounds and encodes a floating-point result value to a specified destination format. This includes processing Overflow, Underflow and Inexact floating-point exceptions and performing flush-to-zero processing on result values.

```
// FPRound()
// =========
//
// The 'fpscr_val' argument supplies FPSCR control bits. Status information is
// updated directly in the FPSCR where appropriate.

bits(N) FPRound(real result, integer N, bits(32) fpscr_val)
    assert N IN {16,32,64};
    assert result != 0.0;

    // Obtain format parameters - minimum exponent, numbers of exponent and fraction bits.
    if N == 16 then
        minimum_exp = -14;  E = 5;  F = 10;
    elsif N == 32 then
        minimum_exp = -126;  E = 8;  F = 23;
    else  // N == 64
        minimum_exp = -1022;  E = 11;  F = 52;

    // Split value into sign, unrounded mantissa and exponent.
    if result < 0.0 then
        sign = '1';  mantissa = -result;
    else
        sign = '0';  mantissa = result;
    exponent = 0;
    while mantissa < 1.0 do
        mantissa = mantissa * 2.0;  exponent = exponent - 1;
    while mantissa >= 2.0 do
        mantissa = mantissa / 2.0;  exponent = exponent + 1;

    // Deal with flush-to-zero.
    if fpscr_val<24> == '1' && N != 16 && exponent < minimum_exp then
        result = FPZero(sign, N);
        FPSCR.UFC = '1';  // Flush-to-zero never generates a trapped exception
    else

        // Start creating the exponent value for the result. Start by biasing the actual exponent
        // so that the minimum exponent becomes 1, lower values 0 (indicating possible underflow).
        biased_exp = Max(exponent - minimum_exp + 1, 0);
        if biased_exp == 0 then mantissa = mantissa / 2^(minimum_exp - exponent);

        // Get the unrounded mantissa as an integer, and the "units in last place" rounding error.
        int_mant = RoundDown(mantissa * 2^F);  // < 2^F if biased_exp == 0, >= 2^F if not
        error = mantissa * 2^F - int_mant;

        // Underflow occurs if exponent is too small before rounding, and result is inexact or
        // the Underflow exception is trapped.
        if biased_exp == 0 && (error != 0.0 || fpscr_val<11> == '1') then
            FPProcessException(FPExc_Underflow, fpscr_val);
```

```
    // Round result according to rounding mode.
    case fpscr_val<23:22> of
        when '00'  // Round to Nearest (rounding to even if exactly halfway)
            round_up = (error > 0.5 || (error == 0.5 && int_mant<0> == '1'));
            overflow_to_inf = TRUE;
        when '01'  // Round towards Plus Infinity
            round_up = (error != 0.0 && sign == '0');
            overflow_to_inf = (sign == '0');
        when '10'  // Round towards Minus Infinity
            round_up = (error != 0.0 && sign == '1');
            overflow_to_inf = (sign == '1');
        when '11'  // Round towards Zero
            round_up = FALSE;
            overflow_to_inf = FALSE;
    if round_up then
        int_mant = int_mant + 1;
        if int_mant == 2^F then      // Rounded up from denormalized to normalized
            biased_exp = 1;
        if int_mant == 2^(F+1) then  // Rounded up to next exponent
            biased_exp = biased_exp + 1;  int_mant = int_mant DIV 2;

    // Deal with overflow and generate result.
    if N != 16 || fpscr_val<26> == '0' then  // Single, double or IEEE half precision
        if biased_exp >= 2^E - 1 then
            result = if overflow_to_inf then FPInfinity(sign, N) else FPMaxNormal(sign, N);
            FPProcessException(FPExc_Overflow, fpscr_val);
            error = 1.0;  // Ensure that an Inexact exception occurs
        else
            result = sign : biased_exp<E-1:0> : int_mant<F-1:0>;
    else                                     // Alternative half precision
        if biased_exp >= 2^E then
            result = sign : Ones(15);
            FPProcessException(FPExc_InvalidOp, fpscr_val);
            error = 0.0;  // Ensure that an Inexact exception does not occur
        else
            result = sign : biased_exp<E-1:0> : int_mant<F-1:0>;

    // Deal with Inexact exception.
    if error != 0.0 then
        FPProcessException(FPExc_Inexact, fpscr_val);

return result;
```

Selection of ARM standard floating-point arithmetic

The `StandardFPSCRValue()` function returns the FPSCR value that selects ARM standard floating-point arithmetic. Most of the arithmetic functions have a Boolean `fpscr_controlled` argument that is `TRUE` for Floating-point operations and `FALSE` for Advanced SIMD operations, and that selects between using the real FPSCR value and this value.

```
// StandardFPSCRValue()
// ====================

bits(32) StandardFPSCRValue()
    return '00000' : FPSCR<26> : '1100000000000000000000000';
```

Floating-point comparisons

The FPCompare() function compares two floating-point numbers, producing a {N, Z, C, V} condition flags result as shown in Table A2-9:

Table A2-9 Effect of a Floating-point comparison on the condition flags

Comparison result	N	Z	C	V
Equal	0	1	1	0
Less than	1	0	0	0
Greater than	0	0	1	0
Unordered	0	0	1	1

This result defines the operation of the VCMP instruction in the Floating-point Extension. The VCMP instruction writes these flag values in the FPSCR. After using a VMRS instruction to transfer them to the APSR, they can control conditional execution as shown in Table A8-1 on page A8-288.

```
// FPCompare()
// ===========

(bit, bit, bit, bit) FPCompare(bits(N) op1, bits(N) op2, boolean quiet_nan_exc,
                               boolean fpscr_controlled)
    assert N IN {32,64};
    fpscr_val = if fpscr_controlled then FPSCR else StandardFPSCRValue();
    (type1,sign1,value1) = FPUnpack(op1, fpscr_val);
    (type2,sign2,value2) = FPUnpack(op2, fpscr_val);
    if type1==FPType_SNaN || type1==FPType_QNaN || type2==FPType_SNaN || type2==FPType_QNaN then
        result = ('0','0','1','1');
        if type1==FPType_SNaN || type2==FPType_SNaN || quiet_nan_exc then
            FPProcessException(FPExc_InvalidOp, fpscr_val);
    else
        // All non-NaN cases can be evaluated on the values produced by FPUnpack()
        if value1 == value2 then
            result = ('0','1','1','0');
        elsif value1 < value2 then
            result = ('1','0','0','0');
        else  // value1 > value2
            result = ('0','0','1','0');
    return result;
```

The FPCompareEQ(), FPCompareGE() and FPCompareGT() functions describe the operation of Advanced SIMD instructions that perform floating-point comparisons.

```
// FPCompareEQ()
// =============

boolean FPCompareEQ(bits(32) op1, bits(32) op2, boolean fpscr_controlled)
    fpscr_val = if fpscr_controlled then FPSCR else StandardFPSCRValue();
    (type1,sign1,value1) = FPUnpack(op1, fpscr_val);
    (type2,sign2,value2) = FPUnpack(op2, fpscr_val);
    if type1==FPType_SNaN || type1==FPType_QNaN || type2==FPType_SNaN || type2==FPType_QNaN then
        result = FALSE;
        if type1==FPType_SNaN || type2==FPType_SNaN then
            FPProcessException(FPExc_InvalidOp, fpscr_val);
    else
        // All non-NaN cases can be evaluated on the values produced by FPUnpack()
        result = (value1 == value2);
    return result;
```

```
// FPCompareGE()
// =============

boolean FPCompareGE(bits(32) op1, bits(32) op2, boolean fpscr_controlled)
    fpscr_val = if fpscr_controlled then FPSCR else StandardFPSCRValue();
    (type1,sign1,value1) = FPUnpack(op1, fpscr_val);
    (type2,sign2,value2) = FPUnpack(op2, fpscr_val);
    if type1==FPType_SNaN || type1==FPType_QNaN || type2==FPType_SNaN || type2==FPType_QNaN then
        result = FALSE;
        FPProcessException(FPExc_InvalidOp, fpscr_val);
    else
        // All non-NaN cases can be evaluated on the values produced by FPUnpack()
        result = (value1 >= value2);
    return result;

// FPCompareGT()
// =============

boolean FPCompareGT(bits(32) op1, bits(32) op2, boolean fpscr_controlled)
    fpscr_val = if fpscr_controlled then FPSCR else StandardFPSCRValue();
    (type1,sign1,value1) = FPUnpack(op1, fpscr_val);
    (type2,sign2,value2) = FPUnpack(op2, fpscr_val);
    if type1==FPType_SNaN || type1==FPType_QNaN || type2==FPType_SNaN || type2==FPType_QNaN then
        result = FALSE;
        FPProcessException(FPExc_InvalidOp, fpscr_val);
    else
        // All non-NaN cases can be evaluated on the values produced by FPUnpack()
        result = (value1 > value2);
    return result;
```

Floating-point maximum and minimum

```
// FPMax()
// =======

bits(N) FPMax(bits(N) op1, bits(N) op2, boolean fpscr_controlled)
    assert N IN {32,64};
    fpscr_val = if fpscr_controlled then FPSCR else StandardFPSCRValue();

Floating-point reciprocal estimate and step

The Advanced SIMD Extension includes instructions that support Newton-Raphson calculation of the reciprocal of a number.

The VRECPE instruction produces the initial estimate of the reciprocal. It uses the following pseudocode functions:

```
// FPRecipEstimate()
// =================

bits(32) FPRecipEstimate(bits(32) operand)

    (type,sign,value) = FPUnpack(operand, StandardFPSCRValue());
    if type == FPType_SNaN || type == FPType_QNaN then
        result = FPProcessNaN(type, operand, StandardFPSCRValue());
    elsif type == FPType_Infinity then
        result = FPZero(sign, 32);
    elsif type == FPType_Zero then
        result = FPInfinity(sign, 32);
        FPProcessException(FPExc_DivideByZero, StandardFPSCRValue());
    elsif Abs(value) >= 2^126 then  // Result underflows to zero of correct sign
        result = FPZero(sign, 32);
        FPProcessException(FPExc_Underflow, StandardFPSCRValue());
    else
        // Operand must be normalized, since denormalized numbers are flushed to zero. Scale to a
        // double-precision value in the range 0.5 <= x < 1.0, and calculate result exponent.
        // Scaled value is positive, with:
        //   exponent = 1022 = double-precision representation of 2^(-1)
        //   fraction = original fraction extended with zeros.
        scaled = '0 01111111110' : operand<22:0> : Zeros(29);
        result_exp = 253 - UInt(operand<30:23>);   // In range 253-252 = 1 to 253-1 = 252

        // Call C function to get reciprocal estimate of scaled value.
        estimate = recip_estimate(scaled);

        // Result is double-precision and a multiple of 1/256 in the range 1 to 511/256. Convert
        // to scaled single-precision result with the original sign bit, the copied high-order
        // fraction bits, and the exponent calculated above.
        result = sign : result_exp<7:0> : estimate<51:29>;

    return result;

// UnsignedRecipEstimate()
// =======================

bits(32) UnsignedRecipEstimate(bits(32) operand)

    if operand<31> == '0' then  // Operands <= 0x7FFFFFFF produce 0xFFFFFFFF
        result = Ones(32);
    else
        // Generate double-precision value = operand * 2^(-32). This has zero sign bit, with:
        //     exponent = 1022 = double-precision representation of 2^(-1)
        //     fraction taken from operand, excluding its most significant bit.
        dp_operand = '0 01111111110' : operand<30:0> : Zeros(21);

        // Call C function to get reciprocal estimate of scaled value.
        estimate = recip_estimate(dp_operand);

        // Result is double-precision and a multiple of 1/256 in the range 1 to 511/256.
        // Multiply by 2^31 and convert to an unsigned integer - this just involves
        // concatenating the implicit units bit with the top 31 fraction bits.
        result = '1' : estimate<51:21>;

    return result;
```

where recip_estimate() is defined by the following C function:

```
double recip_estimate(double a)
{
  int q, s;
  double r;
  q = (int)(a * 512.0);         /* a in units of 1/512 rounded down */
  r = 1.0 / (((double)q + 0.5) / 512.0);  /* reciprocal r */
  s = (int)(256.0 * r + 0.5);   /* r in units of 1/256 rounded to nearest */
  return (double)s / 256.0;
}
```

Table A2-10 shows the results where input values are out of range.

            FPProcessException(FPExc_InvalidOp, fpscr_val);
    elsif type == FPType_Infinity then
        result = FPInfinity(sign, 32);
    elsif type == FPType_Zero then
        result = FPZero(sign, 32);
    else
        result = FPRound(value, 32, fpscr_val);
    return result;
```

The following functions perform conversions between floating-point numbers and integers or fixed-point numbers:

```
// FPToFixed()
// ===========

bits(M) FPToFixed(bits(N) operand, integer M, integer fraction_bits, boolean unsigned,
                  boolean round_towards_zero, boolean fpscr_controlled)
    assert N IN {32,64};
    fpscr_val = if fpscr_controlled then FPSCR else StandardFPSCRValue();
    if round_towards_zero then fpscr_val<23:22> = '11';
    (type,sign,value) = FPUnpack(operand, fpscr_val);

    // For NaNs and infinities, FPUnpack() has produced a value that will round to the
    // required result of the conversion. Also, the value produced for infinities will
    // cause the conversion to overflow and signal an Invalid Operation floating-point
    // exception as required. NaNs must also generate such a floating-point exception.
    if type == FPType_SNaN || type == FPType_QNaN then
        FPProcessException(FPExc_InvalidOp, fpscr_val);

    // Scale value by specified number of fraction bits, then start rounding to an integer
    // and determine the rounding error.
    value = value * 2^fraction_bits;
    int_result = RoundDown(value);
    error = value - int_result;

    // Apply the specified rounding mode.
    case fpscr_val<23:22> of
        when '00'  // Round to Nearest (rounding to even if exactly halfway)
            round_up = (error > 0.5 || (error == 0.5 && int_result<0> == '1'));
        when '01'  // Round towards Plus Infinity
            round_up = (error != 0.0);
        when '10'  // Round towards Minus Infinity
            round_up = FALSE;
        when '11'  // Round towards Zero
            round_up = (error != 0.0 && int_result < 0);
    if round_up then int_result = int_result + 1;

    // Bitstring result is the integer result saturated to the destination size, with
    // saturation indicating overflow of the conversion (signaled as an Invalid
    // Operation floating-point exception).
    (result, overflow) = SatQ(int_result, M, unsigned);
    if overflow then
        FPProcessException(FPExc_InvalidOp, fpscr_val);
    elsif error != 0 then
        FPProcessException(FPExc_Inexact, fpscr_val);

    return result;

// FixedToFP()
// ===========

bits(N) FixedToFP(bits(M) operand, integer N, integer fraction_bits, boolean unsigned,
                  boolean round_to_nearest, boolean fpscr_controlled)
    assert N IN {32,64};
    fpscr_val = if fpscr_controlled then FPSCR else StandardFPSCRValue();
    if round_to_nearest then fpscr_val<23:22> = '00';
    int_operand = if unsigned then UInt(operand) else SInt(operand);
    real_operand = int_operand / 2^fraction_bits;
    if real_operand == 0.0 then
        result = FPZero('0', N);
    else
        result = FPRound(real_operand, N, fpscr_val);
    return result;
```

A2.8 Polynomial arithmetic over {0, 1}

Some Advanced SIMD instructions can operate on polynomials over {0, 1}, see *Data types supported by the Advanced SIMD Extension* on page A2-59. The polynomial data type represents a polynomial in x of the form $b_{n-1}x^{n-1} + \ldots + b_1x + b_0$ where b_k is bit[k] of the value.

The coefficients 0 and 1 are manipulated using the rules of Boolean arithmetic:

- $0 + 0 = 1 + 1 = 0$
- $0 + 1 = 1 + 0 = 1$
- $0 \times 0 = 0 \times 1 = 1 \times 0 = 0$
- $1 \times 1 = 1$.

That is:

- adding two polynomials over {0, 1} is the same as a bitwise exclusive OR
- multiplying two polynomials over {0, 1} is the same as integer multiplication except that partial products are exclusive-ORed instead of being added.

Note

The instructions that can perform polynomials arithmetic over {0, 1} are `VMUL` and `VMULL`, see *VMUL, VMULL (integer and polynomial)* on page A8-958.

A2.8.1 Pseudocode details of polynomial multiplication

In pseudocode, polynomial addition is described by the EOR operation on bitstrings.

Polynomial multiplication is described by the `PolynomialMult()` function:

```
// PolynomialMult()
// ================

bits(M+N) PolynomialMult(bits(M) op1, bits(N) op2)
    result = Zeros(M+N);
    extended_op2 = Zeros(M) : op2;
    for i=0 to M-1
        if op1<i> == '1' then
            result = result EOR LSL(extended_op2, i);
    return result;
```

A2.9 Coprocessor support

The ARM architecture supports coprocessors, to extend the functionality of an ARM processor. The coprocessor instructions summarized in *Coprocessor instructions* on page A4-180 provide access to sixteen coprocessors, described as CP0 to CP15. The following coprocessors are reserved by ARM for specific purposes:

- Coprocessor 15 (CP15) provides system control functionality. This includes architecture and feature identification, as well as control, status information and configuration support.

  For a VMSA implementation, the following sections give a general description of CP15:
  - *About the system control registers for VMSA* on page B3-1444
  - *Organization of the CP15 registers in a VMSA implementation* on page B3-1469
  - *Functional grouping of VMSAv7 system control registers* on page B3-1491.

  For a PMSA implementation, the following sections give a general description of CP15:
  - *About the system control registers for PMSA* on page B5-1772
  - *Organization of the CP15 registers in a PMSA implementation* on page B5-1785
  - *Functional grouping of PMSAv7 system control registers* on page B5-1797.

  CP15 also provides performance monitor registers, see Chapter C12 *The Performance Monitors Extension*.

- Coprocessor 14 (CP14) supports:
  - debug, see Chapter C6 *Debug Register Interfaces*
  - the Thumb Execution Environment, see *Thumb Execution Environment* on page A2-95
  - direct Java bytecode execution, see *Jazelle direct bytecode execution support* on page A2-97.

- Coprocessors 10 and 11 (CP10 and CP11) together support floating-point and vector operations, and the control and configuration of the Floating-point and Advanced SIMD architecture extensions.

- Coprocessors 8, 9, 12, and 13 are reserved for future use by ARM. Any coprocessor access instruction attempting to access one of these coprocessors is UNDEFINED.

Note

In an implementation that includes either or both of the Advanced SIMD Extension and the Floating-point (VFP) Extension, to permit execution of any floating-point or Advanced SIMD instructions, software must enable access to both CP10 and CP11, see *Enabling Advanced SIMD and floating-point support* on page B1-1228.

The following sections give information more information about permitted accesses to coprocessors CP14 and CP15:

- *UNPREDICTABLE and UNDEFINED behavior for CP14 and CP15 accesses* on page B3-1446, for a VMSA implementation

- *UNPREDICTABLE and UNDEFINED behavior for CP14 and CP15 accesses* on page B5-1774, for a PMSA implementation.

Most CP14 and CP15 functions cannot be accessed by software executing at PL0. This manual clearly identifies those functions that can be accessed at PL0.

Software executing at PL1 can enable the unprivileged execution of all load, store, branch and data operation instructions associated with floating-point, Advanced SIMD and execution environment support.

Coprocessors 0 to 7 can provide vendor-specific features.

A2.10 Thumb Execution Environment

Thumb Execution Environment (ThumbEE) is a variant of the Thumb instruction set designed as a target for dynamically generated code. This is code that is compiled on the device, from a portable bytecode or other intermediate or native representation, either shortly before or during execution. ThumbEE provides support for *Just-In-Time* (JIT), *Dynamic Adaptive Compilation* (DAC), and *Ahead-Of-Time* (AOT) compilers, but cannot interwork freely with the ARM and Thumb instruction sets.

From the publication of issue C.a of this manual, ARM deprecates any use of the ThumbEE instruction set.

ThumbEE is particularly suited to languages that feature managed pointers and array types. The processor executes ThumbEE instructions when it is in the ThumbEE instruction set state. For information about instruction set states see *Instruction set state register, ISETSTATE* on page A2-50.

ThumbEE is both the name of the instruction set and the name of the extension that provides support for that instruction set. The ThumbEE Extension is:

- required in implementations of the ARMv7-A profile
- optional in implementations of the ARMv7-R profile.

See *Thumb Execution Environment* on page B1-1239 for system level information about ThumbEE.

A2.10.1 ThumbEE instructions

In ThumbEE state, the processor executes almost the same instruction set as in Thumb state. However some instructions behave differently, some are removed, and some ThumbEE instructions are added.

The key differences are:

- additional instructions to change instruction set in both Thumb state and ThumbEE state
- new ThumbEE instructions to branch to handlers
- null pointer checking on load/store instructions executed in ThumbEE state
- an additional instruction in ThumbEE state to check array bounds
- some other modifications to load, store, and control flow instructions.

For more information about the ThumbEE instructions see Chapter A9 *The ThumbEE Instruction Set*.

A2.10.2 ThumbEE configuration

ThumbEE introduces two new CP14 registers, that Table A2-14 shows. These are 32-bit registers:

Table A2-14 ThumbEE register summary

Name, VMSA[a]	Name, PMSA[a]	CRn	opc1	CRm	opc2	Width	Type	Description
TEECR	TEECR	c0	6	c0	0	32-bit	RW	ThumbEE Configuration Register
TEEHBR	TEEHBR	c1	6	c0	0	32-bit	RW	ThumbEE Handler Base Register

a. VMSA and PMSA definitions of the register fields are identical. These columns link to the descriptions in Chapter B4 and in Chapter B6.

ThumbEE is an unprivileged, user-level facility, and there are no special provisions for using it securely. For more information, see *ThumbEE and the Security Extensions and Virtualization Extensions* on page B1-1239.

Use of HandlerBase

ThumbEE handlers are entered by reference to a HandlerBase address, defined by the TEEHBR. In addition to the handlers for IndexCheck and NullCheck, there are 256 handlers, Handler_00 to Handler_FF, at 32-byte offsets from HandlerBase. Table A2-15 shows the arrangement of handlers relative to the value of HandlerBase:

Table A2-15 Access to ThumbEE handlers

Offset from HandlerBase	Name	Value stored
-0x0008	IndexCheck	Branch to IndexCheck handler
-0x0004	NullCheck	Branch to NullCheck handler
0x0000	Handler_00	Implementation of Handler_00
0x0020	Handler_01	Implementation of Handler_01
…	…	…
0x1FC0	Handler_FE	Implementation of Handler_FE
0x1FE0	Handler_FF	Implementation of Handler_FF

The IndexCheck occurs when a CHKA instruction detects an index out of range. For more information, see *CHKA* on page A9-1124.

The NullCheck occurs when any memory access instruction is executed with a value of 0 in the base register. For more information, see *Null checking* on page A9-1113.

Note

Checks are similar to conditional branches, with the added property that they clear the IT bits when taken.

The other handlers are called using explicit handler call instructions:

- HB and HBL can call any handler, that is, can call Handler_00-Handler_FF
- HBLP and HBP can call only Handler_00-Handler_31.

For more information see the following instruction descriptions:

- *HB, HBL* on page A9-1125
- *HBLP* on page A9-1126
- *HBP* on page A9-1127.

A2.11 Jazelle direct bytecode execution support

From ARMv5TEJ, the architecture requires every system to include an implementation of the Jazelle extension. The Jazelle extension provides architectural support for hardware acceleration of bytecode execution by a *Java Virtual Machine* (JVM).

In the simplest implementations of the Jazelle extension, the processor does not accelerate the execution of any bytecodes, and the JVM uses software routines to execute all bytecodes. Such an implementation is called a *trivial implementation* of the Jazelle extension, and has minimal additional cost compared with not implementing the Jazelle extension at all. An implementation that provides hardware acceleration of bytecode execution is a non-trivial Jazelle implementation.

The Virtualization Extensions require that the Jazelle implementation is the trivial Jazelle implementation.

These requirements for the Jazelle extension mean a JVM can be written to both:

- function correctly on all processors that include a Jazelle extension implementation
- automatically take advantage of the accelerated bytecode execution provided by a processor that includes a non-trivial implementation.

A non-trivial implementation of the Jazelle extension implements a subset of the bytecodes in hardware, choosing bytecodes that:

- can have simple hardware implementations
- account for a large percentage of bytecode execution time.

The required features of a non-trivial implementation are:

- provision of the Jazelle state
- a new instruction, `BXJ`, to enter Jazelle state
- system support that enables an operating system to regulate the use of the Jazelle extension hardware
- system support that enables a JVM to configure the Jazelle extension hardware to its specific needs.

The required features of a trivial implementation are:

- Normally, the Jazelle instruction set state is never entered. In some implementations, an incorrect exception return can cause entry to the Jazelle instruction set state. If this happens, the next instruction executed is treated as UNDEFINED. For more information, see *Unimplemented instruction sets* on page B1-1155.
- The `BXJ` instruction behaves as a `BX` instruction.
- Configuration support that maintains the interface to the Jazelle extension is permanently disabled.

For more information about trivial implementations see *Trivial implementation of the Jazelle extension* on page B1-1244.

A JVM that has been written to take advantage automatically of hardware-accelerated bytecode execution is called an *Enabled JVM* (EJVM).

A2.11.1 Subarchitectures

A processor implementation that includes the Jazelle extension expects the ARM core register values and other resources of the ARM processor to conform to an interface standard defined by the Jazelle implementation when Jazelle state is entered and exited. For example, a specific ARM core register might be reserved for use as the pointer to the current bytecode.

For an EJVM, and any associated debug support, to function correctly, it must be written to comply with the interface standard defined by the acceleration hardware at Jazelle state execution entry and exit points.

An implementation of the Jazelle extension might define other configuration registers in addition to the architecturally defined ones.

The interface standard and any additional configuration registers used for communication with the Jazelle extension are known collectively as the *subarchitecture* of the implementation. They are not described in this manual. Only EJVM implementations and debug or similar software can depend on the subarchitecture. All other software must rely only on the architectural definition of the Jazelle extension given in this manual. A particular subarchitecture is identified by reading the JIDR.

A2.11.2 Jazelle state

While the processor is in Jazelle state, it executes bytecode programs. A bytecode program is defined as an executable object that comprises one or more `class` files, or is derived from and functionally equivalent to one or more `class` files. See *The Java Virtual Machine Specification* for the definition of `class` files.

While the processor is in Jazelle state, the PC identifies the next JVM bytecode to be executed. A JVM bytecode is a bytecode defined in *The Java Virtual Machine Specification*, or a functionally equivalent transformed version of a bytecode defined in that specification.

For the Jazelle extension, the functionality of *Native methods*, as described in *The Java Virtual Machine Specification*, must be specified using only instructions from the ARM, Thumb, and ThumbEE instruction sets.

An implementation of the Jazelle extension must not be documented or promoted as performing any task while it is in Jazelle state other than the acceleration of bytecode programs in accordance with this section and the descriptions in the *The Java Virtual Machine Specification*.

A2.11.3 Jazelle state entry instruction, `BXJ`

ARMv7 includes an ARM instruction similar to `BX`. The `BXJ` instruction has a single register operand that specifies a target instruction set state, ARM state or Thumb state, and branch target address for use if entry to Jazelle state is not available. For more information, see *BXJ* on page A8-354.

Correct entry into Jazelle state involves the EJVM executing the `BXJ` instruction at a time when both:

- the Jazelle extension Control and Configuration registers are initialized correctly, see *Application level configuration and control of the Jazelle extension* on page A2-99
- application level registers and any additional configuration registers are initialized as required by the subarchitecture of the implementation.

Executing `BXJ` with Jazelle extension enabled

Executing a `BXJ` instruction when the JMCR.JE bit is 1 causes the Jazelle hardware to do one of the following:

- enter Jazelle state and start executing bytecodes directly from a SUBARCHITECTURE DEFINED address
- branch to a SUBARCHITECTURE DEFINED handler.

Which of these occurs is SUBARCHITECTURE DEFINED.

The Jazelle subarchitecture can use Application level registers, but not System level registers, to transfer information between the Jazelle extension and the EJVM. There are SUBARCHITECTURE DEFINED restrictions on what Application level registers must contain when a BXJ instruction is executed, and Application level registers have SUBARCHITECTURE DEFINED values when Jazelle state execution ends and ARM or Thumb state execution resumes.

Jazelle subarchitectures and implementations must not use any unallocated bits in Application level registers such as the CPSR or FPSCR. All such bits are reserved for future expansion of the ARM architecture.

Executing `BXJ` with Jazelle extension disabled

If a `BXJ` instruction is executed when the JMCR.JE bit is 0, it is executed identically to a `BX` instruction with the same register operand.

This means that BXJ instructions can be executed freely when the JMCR.JE bit is 0. In particular, if an EJVM determines that it is executing on a processor whose Jazelle extension implementation is trivial or uses an incompatible subarchitecture, it can set JE to 0 and execute correctly. In this case it executes without the benefit of any Jazelle hardware acceleration that might be present.

A2.11.4 Application level configuration and control of the Jazelle extension

The Jazelle extension registers are implemented as CP14 registers. Table A2-16 summarizes the architecturally-defined Jazelle registers. Additional SUBARCHITECTURE DEFINED configuration registers might be provided.

Table A2-16 Jazelle architecturally-defined registers summary

Name, VMSA[a]	Name, PMSA[a]	CRn	opc1	CRm	opc2	Width	Type[b]	Description
JIDR	JIDR	c0	7	c0	0	32-bit	RO	Jazelle ID Register
JOSCR	JOSCR	c1	7	c0	0	32-bit	RW	Jazelle OS Control Register
JMCR	JMCR	c2	7	c0	0	32-bit	RW	Jazelle Main Configuration Register

a. VMSA and PMSA definitions of the register fields are identical. These columns link to the descriptions in Chapter B4 and Chapter B6.

b. Type, for a non-trivial Jazelle implementation. *Trivial implementation of the Jazelle extension* on page B1-1244 describes the register requirements for a trivial Jazelle implementation.

An EJVM can read the JIDR to determine the architecture and subarchitecture under which it is running, and:

- the JMCR gives application level control of Jazelle operation
- the JOSCR gives OS level control of Jazelle operation

The following rules apply to all Jazelle extension control and configuration registers, including any SUBARCHITECTURE DEFINED registers:

- Registers are accessed by CP14 MRC and MCR instructions with <opc1> set to 7.
- The values contained in configuration registers are changed only by the execution of MCR instructions. In particular, they are never changed by Jazelle state execution of bytecodes.
- The access policy for each architecturally-defined register is fully defined in the register description. The access policy of other configuration registers is SUBARCHITECTURE DEFINED.

  When execution is unprivileged, MRC and MCR accesses that are restricted to execution at PL1 or higher are UNDEFINED.

  For more information see *Access to Jazelle registers* on page A2-100.
- In an implementation that includes the Security Extensions, the registers are Common registers, meaning they are common to the Secure and Non-secure security states. For more information, see *Classification of system control registers* on page B3-1451.
- When a configuration register is readable, reading the register:
  - returns the last value written to it
  - has no side-effects.

  When a configuration register is not readable, attempting to read it returns an UNKNOWN value.
- When a configuration register can be written, the effect of writing to it must be idempotent. That is, the overall effect of writing the same value more than once must not differ from the effect of writing it once.

Changes to these CP14 registers have the same synchronization requirements as changes to the CP15 registers. These are described in:

- *Synchronization of changes to system control registers* on page B3-1461 for a VMSA implementation
- *Synchronization of changes to system control registers* on page B5-1777 for a PMSA implementation.

For more information, see *Jazelle state configuration and control* on page B1-1242.

A2.11.5 Access to Jazelle registers

For a non-trivial Jazelle implementation, Table A2-17 shows the access permissions for the Jazelle registers, and how unprivileged access to the registers depends on the value of the JOSCR.

Table A2-17 Access to Jazelle registers in a non-trivial Jazelle implementation

Jazelle register		Unprivileged access		Access at PL1
VMSA	PMSA	JOSCR.CD is 0	JOSCR.CD is 1	
JOSCR	JOSCR	Read and write access UNDEFINED	Read and write access UNDEFINED	Read and write access permitted
JIDR	JIDR	Read access permitted	Read access UNDEFINED	Read access permitted
		Write access UNDEFINED	Write access UNDEFINED	Write access UNPREDICTABLE
JMCR	JMCR	Read access UNDEFINED	Read and write access UNDEFINED	Read and write access permitted
		Write access permitted		
SUBARCHITECTURE DEFINED configuration registers		Read access UNDEFINED	Read and write access UNDEFINED	Read access SUBARCHITECTURE DEFINED
		Write access permitted		Write access permitted

Trivial implementation of the Jazelle extension on page B1-1244 describes the required behavior of Jazelle register accesses for a trivial Jazelle implementation.

A2.11.6 EJVM operation

The following subsections summarize how an EJVM must operate, to meet the requirements of the architecture:

- *Initialization*
- *Bytecode execution*
- *Jazelle exception conditions* on page A2-101
- *Other considerations* on page A2-101.

Initialization

During initialization, the EJVM must first check which subarchitecture is present, by checking the Implementer and Subarchitecture codes in the value read from the JIDR.

If the EJVM is incompatible with the subarchitecture, it must do one of the following:

- write to the JMCR with JE set to 0
- if unaccelerated bytecode execution is unacceptable, generate an error.

If the EJVM is compatible with the subarchitecture, it must write its required configuration to the JMCR and any SUBARCHITECTURE DEFINED configuration registers.

Bytecode execution

The EJVM must contain a handler for each bytecode.

The EJVM initiates bytecode execution by executing a `BXJ` instruction with:

- the register operand specifying the target address of the bytecode handler for the first bytecode of the program
- the Application level registers set up in accordance with the SUBARCHITECTURE DEFINED interface standard.

The bytecode handler:

- performs the data-processing operations required by the bytecode indicated

- determines the address of the next bytecode to be executed
- determines the address of the handler for that bytecode
- performs a `BXJ` to that handler address with the registers again set up to the SUBARCHITECTURE DEFINED interface standard.

Jazelle exception conditions

During bytecode execution, the EJVM might encounter SUBARCHITECTURE DEFINED Jazelle exception conditions that must be resolved by a software handler. For example, in the case of a *configuration invalid* handler, the handler rewrites the desired configuration to the JMCR and to any SUBARCHITECTURE DEFINED configuration registers.

On entry to a Jazelle exception condition handler the contents of the Application level registers are SUBARCHITECTURE DEFINED. This interface to the Jazelle exception condition handler might differ from the interface standard for the bytecode handler, in order to supply information about the Jazelle exception condition.

The Jazelle exception condition handler:

- resolves the Jazelle exception condition
- determines the address of the next bytecode to be executed
- determines the address of the handler for that bytecode
- performs a `BXJ` to that handler address with the registers again set up to the SUBARCHITECTURE DEFINED interface standard.

Other considerations

To ensure application execution and correct interaction with an operating system, an EJVM must only perform operations that are permitted in unprivileged operation. In particular, for register accesses they must only:

- read the JIDR,
- write to the JMCR, and other configuration registers.

An EJVM must not attempt to access the JOSCR.

A2.12 Exceptions, debug events and checks

ARMv7 uses the following terms to describe various types of exceptional condition:

Exceptions In the ARM architecture, an *exception* causes entry into a processor mode that executes software at PL1 or PL2, and execution of a software handler for the exception.

Note

The terms *floating-point exception* and *Jazelle exception condition* do not use this meaning of *exception*. These terms are described later in this list.

Exceptions include:

- reset
- interrupts
- memory system aborts
- undefined instructions
- supervisor calls (SVCs), Secure Monitor calls (SMCs), and hypervisor calls (HVCs).

Most details of exception handling are not visible to application level software, and are described in *Exception handling* on page B1-1164. Aspects that are visible to application level software are:

- The `SVC` instruction causes a Supervisor Call exception. This provides a mechanism for unprivileged software to make a call to the operating system, or other system component that is accessible only at PL1.
- In an implementation that includes the Security Extensions, the `SMC` instruction causes a Secure Monitor Call exception, but only if software execution is at PL1 or higher. Unprivileged software can only cause a Secure Monitor Call exception by methods defined by the operating system, or by another component of the software system that executes at PL1 or higher.
- In an implementation that includes the Virtualization Extensions, the `HVC` instruction causes a Hypervisor Call exception, but only if software execution is at PL1 or higher. Unprivileged software can only cause a Hypervisor Call exception by methods defined by the hypervisor, or by another component of the software system that executes at PL1 or higher.
- The `WFI` instruction provides a hint that nothing needs to be done until the processor takes an interrupt or similar exception, see *Wait For Interrupt* on page B1-1202. This permits the processor to enter a low-power state until that happens.
- The `WFE` instruction provides a hint that nothing needs to be done until either an `SEV` instruction generates an *event*, or the processor takes an interrupt or similar exception, see *Wait For Event and Send Event* on page B1-1199. This permits the processor to enter a low-power state until one of these happens.

Floating-point exceptions

These relate to exceptional conditions encountered during floating-point arithmetic, such as division by zero or overflow. For more information see:

- *Floating-point exceptions* on page A2-70
- *FPSCR, Floating-point Status and Control Register, VMSA* on page B4-1569, or *FPSCR, Floating-point Status and Control Register, PMSA* on page B6-1845
- ANSI/IEEE Std. 754, *IEEE Standard for Binary Floating-Point Arithmetic*.

Jazelle exception conditions

These are conditions that cause Jazelle hardware acceleration to exit into a software handler, as described in *Jazelle exception conditions* on page A2-101.

Debug events These are conditions that cause a debug system to take action. Most aspects of debug events are not visible to application level software, and are described in Chapter C3 *Debug Events*. Aspects that are visible to application level software include:

- The `BKPT` instruction causes a BKPT instruction debug event to occur, see *BKPT instruction debug events* on page C3-2038.
- The `DBG` instruction provides a hint to the debug system.

Checks These are provided in the ThumbEE Extension. A check causes an unconditional branch to a specific handler entry point. The base address of the ThumbEE check handlers is held in the TEEHBR.

Chapter A3
Application Level Memory Model

This chapter gives an application level view of the memory model. It contains the following sections:

- *Address space* on page A3-106
- *Alignment support* on page A3-108
- *Endian support* on page A3-110
- *Synchronization and semaphores* on page A3-114
- *Memory types and attributes and the memory order model* on page A3-125
- *Access rights* on page A3-141
- *Virtual and physical addressing* on page A3-144
- *Memory access order* on page A3-145
- *Caches and memory hierarchy* on page A3-155.

Note

In this chapter, system register names usually link to the description of the register in Chapter B4 *System Control Registers in a VMSA implementation*, for example SCTLR. If the register is included in a PMSA implementation, then it is also described in Chapter B6 *System Control Registers in a PMSA implementation*.

A3.1 Address space

The ARM architecture Application level memory model uses a single, flat address space of 2^{32} 8-bit bytes, covering 4GBytes. Byte addresses are treated as unsigned numbers, running from 0 to 2^{32} - 1. The address space is also regarded as:

- 2^{30} 32-bit words:
  - the address of each word is word-aligned, meaning that the address is divisible by 4 and the least significant bits of the address are `0b00`
  - the word at word-aligned address A consists of the four bytes with addresses A, A+1, A+2 and A+3.
- 2^{31} 16-bit halfwords:
  - the address of each halfword is halfword-aligned, meaning that the address is divisible by 2 and the least significant bit of the address is 0
  - the halfword at halfword-aligned address A consists of the two bytes with addresses A and A+1.

In some situations the ARM architecture supports accesses to halfwords and words that are not aligned to the appropriate access size, see *Alignment support* on page A3-108.

Normally, address calculations are performed using ordinary integer instructions. This means that the address wraps around if the calculation overflows or underflows the address space. Another way of describing this is that any address calculation is reduced modulo 2^{32}.

A3.1.1 Address space overflow or underflow

Address space overflow occurs when the memory address increments beyond the top byte of the address space at `0xFFFFFFFF`. When this happens, the address wraps round, so that, for example, incrementing `0xFFFFFFFF` by 2 gives a result of `0x00000001`.

Address space underflow occurs when the memory address decrements below the first byte of the address space at `0x00000000`. When this happens, the address wraps round, so that, for example, decrementing `0x00000002` by 4 gives a result of `0xFFFFFFFE`.

When a processor performs normal sequential execution of instructions, after each instruction it finds the address of the next instruction by calculating:

```
(address_of_current_instruction) + (size_of_executed_instruction)
```

This calculation can result in address space overflow.

Note

The size of the executed instruction depends on the current instruction set, and can depend on the instruction executed.

Any multi-byte memory access that depends on address space overflow or underflow is UNPREDICTABLE. This applies to both data and instruction accesses.

The following rules define the accesses that are UNPREDICTABLE:

1. If the processor executes an instruction for which the instruction address, size, and alignment mean it contains the bytes `0xFFFFFFFF` and `0x00000000`, the result is UNPREDICTABLE.

   Examples of this UNPREDICTABLE behavior include:
   - relying on sequential execution of the instruction at `0x00000000` after any of:
     - executing a 4-byte instruction at `0xFFFFFFFC`
     - executing a 2-byte instruction at `0xFFFFFFFE`
     - executing a 1-byte instruction at `0xFFFFFFFF`.

- attempting to execute an instruction that spans the top of memory, for example:
  - a 4-byte instruction at `0xFFFFFFFE`
  - a 2-byte instruction at `0xFFFFFFFF`.

2. If the processor executes a load or store instruction for which the computed address, total access size, and alignment mean it accesses the bytes `0xFFFFFFFF` and `0x00000000`, the result is UNPREDICTABLE.

   Examples of this UNPREDICTABLE behavior include:

   - attempting to perform an unaligned load or store operation that spans the top of memory, for example:
     - a word load or store from or to address `0xFFFFFFFD`
     - a halfword load or store from or to address `0xFFFFFFFF`
   - attempting to perform a multiple load or store operation that spans the top of memory, for example:
     - a two-word load or store from or to addresses `0xFFFFFFFC` and `0x00000000`
     - an Advanced SIMD multiple-element load or store that includes bytes `0xFFFFFFFF` and `0x00000000`.

This UNPREDICTABLE behavior only applies to instructions that are executed, including those that fail their condition code check. Most ARM implementations fetch instructions ahead of the currently-executing instruction. If this *prefetching* overflows the top of the address space, it does not cause UNPREDICTABLE behavior unless the prefetched instruction with an overflowed address is executed.

Note

In some cases, instructions that operate on multiple words can decrement the memory address by 4 after each word access. If this calculation underflows the address space, the result is UNPREDICTABLE.

A3.2 Alignment support

Instructions in the ARM architecture are aligned as follows:

- ARM instructions are word-aligned
- Thumb and ThumbEE instructions are halfword-aligned
- Java bytecodes are byte-aligned.

In the ARMv7 architecture, some load and store instructions support unaligned data accesses, as described in *Unaligned data access*.

For more information about the alignment support in previous versions of the ARM architecture, see *Alignment* on page AppxL-2504.

A3.2.1 Unaligned data access

An ARMv7 implementation must support unaligned data accesses by some load and store instructions, as Table A3-1 shows. Software can set the SCTLR.A bit to control whether a misaligned access by one of these instructions causes an Alignment fault Data Abort exception.

Table A3-1 Alignment requirements of load/store instructions

Instructions	Alignment check	Result if check fails when:	
		SCTLR.A is 0	SCTLR.A is 1
LDRB, LDREXB, LDRBT, LDRSB, LDRSBT, STRB, STREXB, STRBT, SWPB, TBB	None	-	-
LDRH, LDRHT, LDRSH, LDRSHT, STRH, STRHT, TBH	Halfword	Unaligned access	Alignment fault
LDREXH, STREXH	Halfword	Alignment fault	Alignment fault
LDR, LDRT, STR, STRT PUSH, encodings T3 and A2 only POP, encodings T3 and A2 only	Word	Unaligned access	Alignment fault
LDREX, STREX	Word	Alignment fault	Alignment fault
LDREXD, STREXD	Doubleword	Alignment fault	Alignment fault
All forms of LDM and STM, LDRD, RFE, SRS, STRD, SWP PUSH, except for encodings T3 and A2 POP, except for encodings T3 and A2	Word	Alignment fault	Alignment fault
LDC, LDC2, STC, STC2	Word	Alignment fault	Alignment fault
VLDM, VLDR, VPOP, VPUSH, VSTM, VSTR	Word	Alignment fault	Alignment fault
VLD1, VLD2, VLD3, VLD4, VST1, VST2, VST3, VST4, all with standard alignment[a]	Element size	Unaligned access	Alignment fault
VLD1, VLD2, VLD3, VLD4, VST1, VST2, VST3, VST4, all with :<align> specified[a, b]	As specified by :<align>	Alignment fault	Alignment fault

a. These element and structure load/store instructions are only in the Advanced SIMD Extension to the ARMv7 ARM and Thumb instruction sets. ARMv7 does not support the pre-ARMv6 alignment model, so software cannot use that model with these instructions.

b. Previous versions of this document used @<align> to specify alignment. Both forms are supported, see *Advanced SIMD addressing mode* on page A7-277 for more information.

A3.2.2 Cases where unaligned accesses are UNPREDICTABLE

The following cases cause the resulting unaligned accesses to be UNPREDICTABLE, and overrule any permitted load or store behavior shown in Table A3-1 on page A3-108:

- Any load instruction that is not faulted by the alignment restrictions shown in Table A3-1 on page A3-108 and that loads the PC has UNPREDICTABLE behavior if the address it loads from is not word-aligned.
- In an implementation that does not include the Virtualization Extensions, any unaligned access that is not faulted by the alignment restrictions shown in Table A3-1 on page A3-108 and that accesses memory with the Strongly-ordered or Device memory attribute has UNPREDICTABLE behavior.

Note

— In an implementation that includes the Virtualization Extensions, such an unaligned access to Device or Strongly-ordered memory generates an Alignment fault, see *Alignment faults* on page B3-1402.

— *Memory types and attributes and the memory order model* on page A3-125 describes the Strongly-ordered and Device memory attributes.

A3.2.3 Unaligned data access restrictions in ARMv7 and ARMv6

ARMv7 and ARMv6 have the following restrictions on unaligned data accesses:

- Accesses are not guaranteed to be single-copy atomic except at the byte access level, see *Atomicity in the ARM architecture* on page A3-127. An access can be synthesized out of a series of aligned operations in a shared memory system without guaranteeing locked transaction cycles.
- Unaligned accesses typically take a number of additional cycles to complete compared to a naturally aligned transfer. The real-time implications must be analyzed carefully and key data structures might need to have their alignment adjusted for optimum performance.
- An operation that performs an unaligned access can abort on any memory access that it makes, and can abort on more than one access. This means that an unaligned access that occurs across a page boundary can generate an abort on either side of the boundary, or on both sides of the boundary.

Shared memory schemes must not rely on seeing single-copy atomic updates of unaligned data of loads and stores for data items larger than byte wide. For more information, see *Atomicity in the ARM architecture* on page A3-127.

Unaligned access operations must not be used for accessing memory-mapped registers in a Device or Strongly-ordered memory region.

A3.3 Endian support

The rules in *Address space* on page A3-106 require that for a word-aligned address A:

- the doubleword at address A comprises the bytes at addresses A, A+1, A+2, A+3, A+4, A+5, A+6, and A+7
- the word:
  - at address A comprises the bytes at addresses A, A+1, A+2 and A+3
  - at address A+4 comprises the bytes at addresses A+4, A+5, A+6 and A+7
- the halfword:
  - at address A comprises the bytes at addresses A and A+1
  - at address A+2 comprises the bytes at addresses A+2 and A+3
  - at address A+4 comprises the bytes at addresses A+4 and A+5
  - at address A+6 comprises the bytes at addresses A+6 and A+7
- this means that:
  - the doubleword at address A comprises the words at addresses A and A+4
  - the word at address A comprises the halfwords at addresses A and A+2
  - the word at address A+4 comprises the halfwords at addresses A+4 and A+6.

However, this does not specify completely the mappings between words, halfwords, and bytes.

A memory system uses one of the two following mapping schemes. This choice is called the endianness of the memory system.

In a *little-endian* memory system:

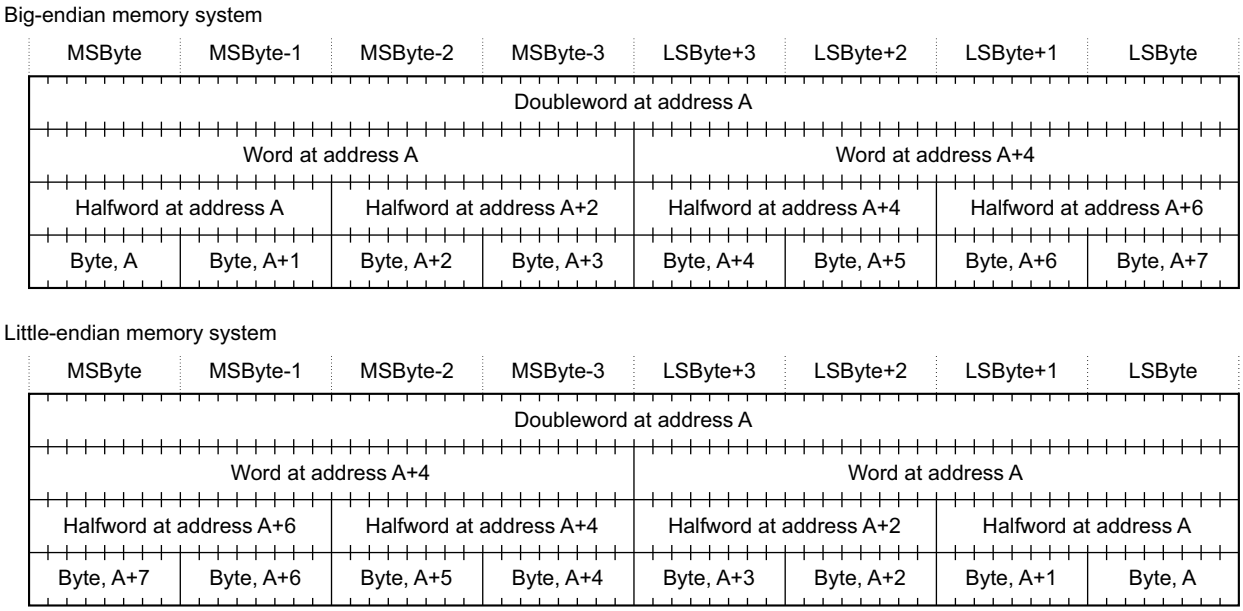
- the byte, halfword, or word at an address is the least significant byte, halfword, or word in the doubleword at that address
- the byte or halfword at an address is the least significant byte or halfword in the word at that address
- the byte at an address is the least significant byte in the halfword at that address.

In a *big-endian* memory system:

- the byte, halfword, or word at an address is the most significant byte, halfword or word in the doubleword at that address
- the byte or halfword at an address is the most significant byte or halfword in the word at that address
- the byte at an address is the most significant byte in the halfword at that address.

For an address A, Figure A3-1 on page A3-111 shows, for big-endian and little-endian memory systems, the relationship between:

- the doubleword at address A
- the words at addresses A and A+4
- the halfwords at addresses A, A+2, A+4, and A+6
- the bytes at addresses A, A+1, A+2, A+3, A+4, A+5, A+6, and A+7.



In this figure, *Byte, A+1* is an abbreviation for *Byte at address A+1*

Figure A3-1 Endianness relationships

The big-endian and little-endian mapping schemes determine the order in which the bytes of a doubleword, word or halfword are interpreted. For example, a load of a word from address `0x1000` always results in an access to the bytes at memory locations `0x1000`, `0x1001`, `0x1002`, and `0x1003`. The endianness mapping scheme determines the significance of these four bytes.

A3.3.1 Instruction endianness

In ARMv7-A, the mapping of instruction memory is always little-endian. In ARMv7-R, instruction endianness can be controlled at the system level, see *Instruction endianness static configuration, ARMv7-R only* on page A3-112.

Note

For information about data memory endianness control, see *Endianness mapping register, ENDIANSTATE* on page A2-53.

Before ARMv7, the ARM architecture included legacy support for an alternative big-endian memory model, described as BE-32 and controlled by SCTLR.B bit, bit[7] of the register, see *Endian configuration and control* on page AppxL-2516. ARMv7 does not support BE-32 operation, and bit SCTLR[7] is RAZ/SBZP.

Where legacy object code for ARM processors contains instructions with a big-endian byte order, the removal of support for BE-32 operation requires the instructions in the object files to have their bytes reversed for the code to be executed on an ARMv7 processor. This means that:

- each Thumb instruction, whether a 32-bit Thumb instruction or a 16-bit Thumb instruction, must have the byte order of each halfword of instruction reversed
- each ARM instruction must have the byte order of each word of instruction reversed.

For most situations, this can be handled in the link stage of a tool-flow, provided the object files include sufficient information to permit this to happen. In practice, this is the situation for all applications with the ARMv7-A profile.

For applications of the ARMv7-R profile, there are some legacy code situations where the arrangement of the bytes in the object files cannot be adjusted by the linker. For these object files to be used by an ARMv7-R processor the byte order of the instructions must be reversed by the processor at runtime. Therefore, the ARMv7-R profile permits configuration of the instruction endianness.

Instruction endianness static configuration, ARMv7-R only

To provide support for legacy big-endian object code, the ARMv7-R profile supports optional byte order reversal hardware as a static option from reset. The ARMv7-R profile includes a read-only bit in the CP15 Control Register, SCTLR.IE, bit[31], that indicates the instruction endianness configuration.

A3.3.2 Element size and endianness

The effect of the endianness mapping on data transfers depends on the size of the data element or elements transferred by the load/store instructions. Table A3-2 lists the element sizes of all the load/store instructions, for all instruction sets.

Table A3-2 Element size of load/store instructions

Instructions	Element size
LDRB, LDREXB, LDRBT, LDRSB, LDRSBT, STRB, STREXB, STRBT, SWPB, TBB	Byte
LDRH, LDREXH, LDRHT, LDRSH, LDRSHT, STRH, STREXH, STRHT, TBH	Halfword
LDR, LDRT, LDREX, STR, STRT, STREX	Word
LDRD, LDREXD, STRD, STREXD	Word
All forms of LDM, PUSH, POP, RFE, SRS, all forms of STM, SWP	Word
LDC, LDC2, STC, STC2	Word
Forms of VLDM, VLDR, VPOP, VPUSH, VSTM, VSTR that transfer 32-bit Si registers	Word
Forms of VLDM, VLDR, VPOP, VPUSH, VSTM, VSTR that transfer 64-bit Di registers	Doubleword
VLD1, VLD2, VLD3, VLD4, VST1, VST2, VST3, VST4	Element size of the Advanced SIMD access

A3.3.3 Instructions to reverse bytes in an ARM core register

An application or device driver might have to interface to memory-mapped peripheral registers or shared memory structures that are not the same endianness as the internal data structures. Similarly, the endianness of the operating system might not match that of the peripheral registers or shared memory. In these cases, the processor requires an efficient method to transform explicitly the endianness of the data.

In ARMv7, in the ARM and Thumb instruction sets, the following instructions provide this functionality:

`REV` Reverse word (four bytes) register, for transforming big-endian and little-endian 32-bit representations, see *REV* on page A8-562.

`REVSH` Reverse halfword and sign-extend, for transforming signed 16-bit representations, see *REVSH* on page A8-566.

`REV16` Reverse packed halfwords in a register for transforming big-endian and little-endian 16-bit representations, see *REV16* on page A8-564.

A3.3.4 Endianness in Advanced SIMD

Advanced SIMD element load/store instructions transfer vectors of elements between memory and the Advanced SIMD register bank. An instruction specifies both the length of the transfer and the size of the data elements being transferred. This information is used by the processor to load and store data correctly in both big-endian and little-endian systems.

Consider, for example, the instruction:

```
VLD1.16 {D0}, [R1]
```

This loads a 64-bit register with four 16-bit values. The four elements appear in the register in array order, with the lowest indexed element fetched from the lowest address. The order of bytes in the elements depends on the endianness configuration, as shown in Figure A3-2. Therefore, the order of the elements in the registers is the same regardless of the endianness configuration.

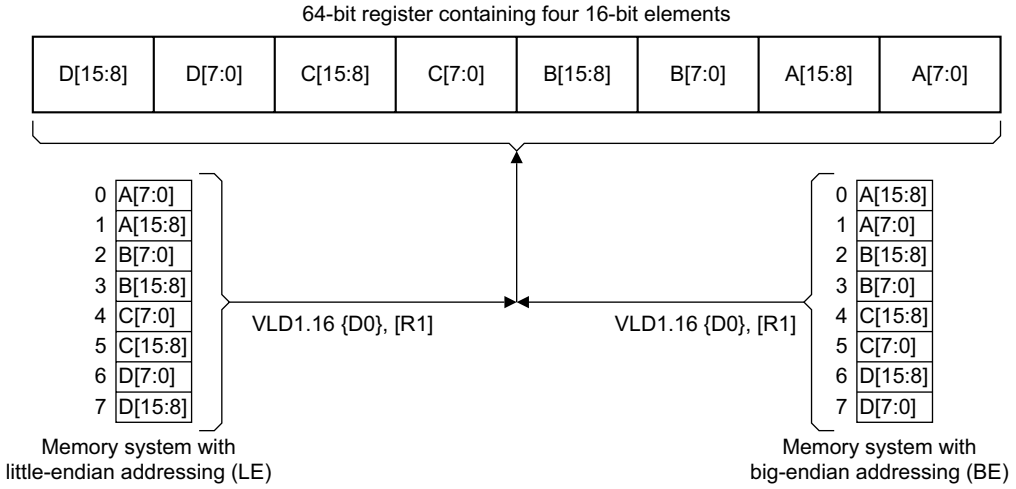


Figure A3-2 Advanced SIMD byte order example

For information about the alignment of Advanced SIMD instructions see *Unaligned data access* on page A3-108.

A3.4 Synchronization and semaphores

In architecture versions before ARMv6, support for the synchronization of shared memory depends on the SWP and SWPB instructions. These are read-locked-write operations that swap register contents with memory, and are described in *SWP, SWPB* on page A8-722. These instructions support basic busy/free semaphore mechanisms, but do not support mechanisms that require calculation to be performed on the semaphore between the read and write phases.

From ARMv6, ARM deprecates any use of SWP or SWPB, and the ARMv7 Virtualization Extensions make these instructions OPTIONAL and deprecated.

Note

- ARM strongly recommends that all software uses the synchronization primitives described in this section, rather than SWP or SWPB.
- If an implementation does not support the SWP and SWPB instructions, the ID_ISAR0.Swap_instrs and ID_ISAR4.SWP_frac fields are zero, see *About the Instruction Set Attribute registers* on page B7-1950.

ARMv6 introduced a new mechanism to support more comprehensive non-blocking synchronization of shared memory, using *synchronization primitives* that scale for multiprocessor system designs. ARMv7 extends support for this mechanism, and provides the following synchronization primitives in the ARM and Thumb instruction sets:

- Load-Exclusives:
  - LDREX, see *LDREX* on page A8-432
  - LDREXB, see *LDREXB* on page A8-434
  - LDREXD, see *LDREXD* on page A8-436
  - LDREXH, see *LDREXH* on page A8-438
- Store-Exclusives:
  - STREX, see *STREX* on page A8-690
  - STREXB, see *STREXB* on page A8-692
  - STREXD, see *STREXD* on page A8-694
  - STREXH, see *STREXH* on page A8-696
- Clear-Exclusive, CLREX, see *CLREX* on page A8-360.

Note

This section describes the operation of a Load-Exclusive/Store-Exclusive pair of synchronization primitives using, as examples, the LDREX and STREX instructions. The same description applies to any other pair of synchronization primitives:

- LDREXB used with STREXB
- LDREXD used with STREXD
- LDREXH used with STREXH.

Software must use a Load-Exclusive instruction only with the corresponding Store-Exclusive instruction.

The model for the use of a Load-Exclusive/Store-Exclusive instruction pair, accessing a non-aborting memory address x is:

- The Load-Exclusive instruction reads a value from memory address x.
- The corresponding Store-Exclusive instruction succeeds in writing back to memory address x only if no other observer, process, or thread has performed a more recent store to address x. The Store-Exclusive operation returns a status bit that indicates whether the memory write succeeded.

A Load-Exclusive instruction tags a small block of memory for exclusive access. The size of the tagged block is IMPLEMENTATION DEFINED, see *Tagging and the size of the tagged memory block* on page A3-121. A Store-Exclusive instruction to the same address clears the tag.

Note

In this section, the term processor includes any observer that can generate a Load-Exclusive or a Store-Exclusive.

A3.4.1 Exclusive access instructions and Non-shareable memory regions

For memory regions that do not have the *Shareable* attribute, the exclusive access instructions rely on a *local monitor* that tags any address from which the processor executes a Load-Exclusive. Any non-aborted attempt by the same processor to use a Store-Exclusive to modify any address is guaranteed to clear the tag.

A Load-Exclusive performs a load from memory, and:

- the executing processor tags the physical memory address for exclusive access
- the local monitor of the executing processor transitions to the Exclusive Access state.

A Store-Exclusive performs a conditional store to memory, that depends on the state of the local monitor:

If the local monitor is in the Exclusive Access state

- If the address of the Store-Exclusive is the same as the address that has been tagged in the monitor by an earlier Load-Exclusive, then the store occurs, otherwise it is IMPLEMENTATION DEFINED whether the store occurs.
- A status value is returned to a register:
  - if the store took place the status value is 0
  - otherwise, the status value is 1.
- The local monitor of the executing processor transitions to the Open Access state.

If the local monitor is in the Open Access state

- no store takes place
- a status value of 1 is returned to a register.
- the local monitor remains in the Open Access state.

The Store-Exclusive instruction defines the register to which the status value is returned.

When a processor writes using any instruction other than a Store-Exclusive:

- if the write is to a physical address that is not covered by its local monitor the write does not affect the state of the local monitor
- if the write is to a physical address that is covered by its local monitor it is IMPLEMENTATION DEFINED whether the write affects the state of the local monitor.

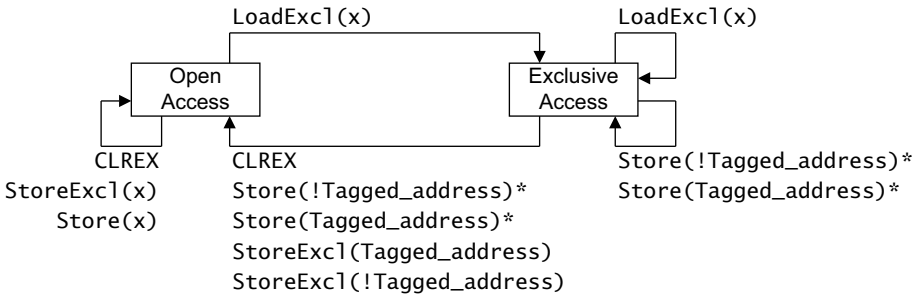
If the local monitor is in the Exclusive Access state and the processor performs a Store-Exclusive to any address other than the last one from which it performed a Load-Exclusive, it is IMPLEMENTATION DEFINED whether the store updates memory, but in all cases the local monitor is reset to the Open Access state. This mechanism:

- is used on a context switch, see *Context switch support* on page A3-122
- must be treated as a software programming error in all other cases.

Note

It is IMPLEMENTATION DEFINED whether a store to a tagged physical address causes a tag in the local monitor to be cleared if that store is by an observer other than the one that caused the physical address to be tagged.

Figure A3-3 on page A3-116 shows the state machine for the local monitor. Table A3-3 on page A3-116 shows the effect of each of the operations shown in the figure.



Operations marked * are possible alternative IMPLEMENTATION DEFINED options.
In the diagram: `LoadExcl` represents any Load-Exclusive instruction
`StoreExcl` represents any Store-Exclusive instruction
`Store` represents any other store instruction.

Any `LoadExcl` operation updates the tagged address to the most significant bits of the address x used for the operation.

Figure A3-3 Local monitor state machine diagram

For more information about tagging see *Tagging and the size of the tagged memory block* on page A3-121.

Note

For the local monitor state machine, as shown in Figure A3-3:

- The IMPLEMENTATION DEFINED options for the local monitor are consistent with the local monitor being constructed so that it does not hold any physical address, but instead treats any access as matching the address of the previous `LoadExcl`.
- A local monitor implementation can be unaware of Load-Exclusive and Store-Exclusive operations from other processors.
- The architecture does not require a load instruction by another processor, that is not a Load-Exclusive instruction, to have any effect on the local monitor.
- It is IMPLEMENTATION DEFINED whether the transition from Exclusive Access to Open Access state occurs when the `Store` or `StoreExcl` is from another observer.

Table A3-3 shows the effect of the operations shown in Figure A3-3.

Table A3-3 Effect of Exclusive instructions and write operations on the local monitor

Initial state	Operation[a]	Effect	Final state
Open Access	`CLREX`	No effect	Open Access
	`StoreExcl(x)`	Does not update memory, returns status 1	Open Access
	`LoadExcl(x)`	Loads value from memory, tags address x	Exclusive Access
	`Store(x)`	Updates memory, no effect on monitor	Open Access
Exclusive Access	`CLREX`	Clears tagged address	Open Access
	`StoreExcl(t)`	Updates memory, returns status 0	Open Access
	`StoreExcl(!t)`	Updates memory, returns status 0[b]	Open Access
		Does not update memory, returns status 1[b]	
	`LoadExcl(x)`	Loads value from memory, changes tag to address x	Exclusive Access

Table A3-3 Effect of Exclusive instructions and write operations on the local monitor (continued)

Initial state	Operation[a]	Effect	Final state
Exclusive Access	`Store(!t)`	Updates memory	Exclusive Access[b]
			Open Access[b]
	`Store(t)`	Updates memory	Exclusive Access[b]
			Open Access[b]

a. In the table:
`LoadExcl` represents any Load-Exclusive instruction
`StoreExcl` represents any Store-Exclusive instruction
`Store` represents any store operation other than a Store-Exclusive operation.
t is the tagged address, bits[31:a] of the address of the last Load-Exclusive instruction. For more information, see *Tagging and the size of the tagged memory block* on page A3-121.

b. IMPLEMENTATION DEFINED alternative actions.

Note

Normal memory that is Inner Non-cacheable, Outer Non-cacheable is inherently coherent between different processors, and it is IMPLEMENTATION DEFINED whether such memory, if it does not have the Shareable attribute, is treated as Non-shareable or as Shareable.

Changes to the local monitor state resulting from speculative execution

The architecture permits a local monitor to transition to the Open Access state as a result of speculation, or from some other cause. This is in addition to the transitions to Open Access state caused by the architectural execution of an operation shown in Table A3-3 on page A3-116.

An implementation must ensure that:

- the local monitor cannot be seen to transition to the Exclusive Access state except as a result of the architectural execution of one of the operations shown in Table A3-3 on page A3-116
- any transition of the local monitor to the Open Access state not caused by the architectural execution of an operation shown in Table A3-3 on page A3-116 must not indefinitely delay forward progress of execution.

A3.4.2 Exclusive access instructions and Shareable memory regions

For memory regions that have the *Shareable* attribute, exclusive access instructions rely on:

- A *local monitor* for each processor in the system, that tags any address from which the processor executes a Load-Exclusive. The local monitor operates as described in *Exclusive access instructions and Non-shareable memory regions* on page A3-115, except that for Shareable memory any Store-Exclusive is then subject to checking by the global monitor if it is described in that section as doing at least one of:
  - updating memory
  - returning a status value of 0.

  The local monitor can ignore accesses from other processors in the system.
- A *global monitor* that tags a physical address as exclusive access for a particular processor. This tag is used later to determine whether a Store-Exclusive to that address that has not been failed by the local monitor can occur. Any successful write to the tagged address by any other observer in the shareability domain of the memory location is guaranteed to clear the tag. For each processor in the system, the global monitor:
  - can hold at least one tagged address
  - maintains a state machine for each tagged address it can hold.

Note

For each processor, the architecture only requires global monitor support for a single tagged address. Any situation that might benefit from the use of multiple tagged addresses on a single processor is UNPREDICTABLE, see *Load-Exclusive and Store-Exclusive usage restrictions* on page A3-122.

In addition, in an implementation that includes the Large Physical Address Extension, when the implementation is using the Short-descriptor translation table format, it is IMPLEMENTATION DEFINED whether Load-Exclusive and Store-Exclusive accesses to Non-shareable regions with the Normal, Inner Non-cacheable, Outer Non-cacheable attribute use the global monitor in addition to the local monitor.

Note

The global monitor can either reside in a processor block or exist as a secondary monitor at the memory interfaces.The IMPLEMENTATION DEFINED aspects of the monitors mean that the global monitor and local monitor can be combined into a single unit, provided that unit performs the global monitor and local monitor functions defined in this manual.

For Shareable regions of memory, in some implementations and for some memory types, the properties of the global monitor can be met only by functionality outside the processor. Some system implementations might not implement this functionality for all regions of memory, In particular, this can apply to:

- any type of memory in the system implementation that does not support hardware cache coherency
- Non-cacheable memory, or memory treated as Non-cacheable, in an implementation that does support hardware cache coherency.

In such a system, it is defined by the system:

- whether the global monitor is implemented
- if the global monitor is implemented, which address ranges or memory types it monitors.

The behavior of Load Exclusive and Store Exclusive instructions when accessing a memory address not monitored by the global monitor is UNPREDICTABLE.

Note

An implementation can combine the functionality of the global and local monitors into a single unit.

Operation of the global monitor

A Load-Exclusive from Shareable memory performs a load from memory, and causes the physical address of the access to be tagged as exclusive access for the requesting processor. This access also causes the exclusive access tag to be removed from any other physical address that has been tagged by the requesting processor.

The global monitor only supports a single outstanding exclusive access to Shareable memory per processor. A Load-Exclusive by one processor has no effect on the global monitor state for any other processor.

Store-Exclusive performs a conditional store to memory:

- The store is guaranteed to succeed only if the physical address accessed is tagged as exclusive access for the requesting processor and both the local monitor and the global monitor state machines for the requesting processor are in the Exclusive Access state. In this case:
  - a status value of 0 is returned to a register to acknowledge the successful store
  - the final state of the global monitor state machine for the requesting processor is IMPLEMENTATION DEFINED
  - if the address accessed is tagged for exclusive access in the global monitor state machine for any other processor then that state machine transitions to Open Access state.

- If no address is tagged as exclusive access for the requesting processor, the store does not succeed:
  - a status value of 1 is returned to a register to indicate that the store failed
  - the global monitor is not affected and remains in Open Access state for the requesting processor.
- If a different physical address is tagged as exclusive access for the requesting processor, it is IMPLEMENTATION DEFINED whether the store succeeds or not:
  - if the store succeeds a status value of 0 is returned to a register, otherwise a value of 1 is returned
  - if the global monitor state machine for the processor was in the Exclusive Access state before the Store-Exclusive it is IMPLEMENTATION DEFINED whether that state machine transitions to the Open Access state.

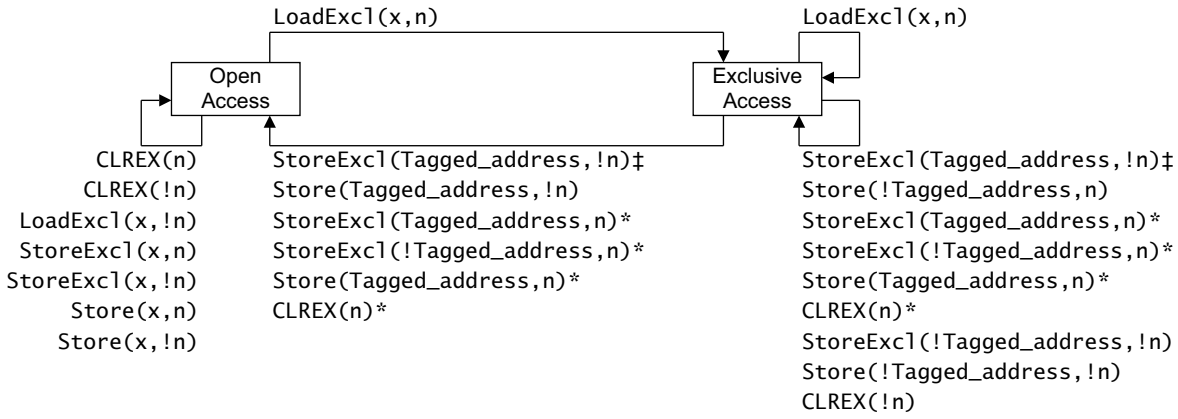
The Store-Exclusive instruction defines the register to which the status value is returned.

In a shared memory system, the global monitor implements a separate state machine for each processor in the system. The state machine for accesses to Shareable memory by processor (n) can respond to all the Shareable memory accesses visible to it. This means it responds to:

- accesses generated by the associated processor (n)
- accesses generated by the other observers in the shareability domain of the memory location (!n).

In a shared memory system, the global monitor implements a separate state machine for each observer that can generate a Load-Exclusive or a Store-Exclusive in the system.

Figure A3-4 shows the state machine for processor(n) in a global monitor. Table A3-4 on page A3-120 shows the effect of each of the operations shown in the figure.



‡StoreExcl(Tagged_Address,!n) clears the monitor only if the StoreExcl updates memory
Operations marked * are possible alternative IMPLEMENTATION DEFINED options.
In the diagram: LoadExcl represents any Load-Exclusive instruction
StoreExcl represents any Store-Exclusive instruction
Store represents any other store instruction.

Any LoadExcl operation updates the tagged address to the most significant bits of the address x used for the operation.

Figure A3-4 Global monitor state machine diagram for processor(n) in a multiprocessor system

For more information about tagging see *Tagging and the size of the tagged memory block* on page A3-121.

Note

For the global monitor state machine, as shown in Figure A3-4 on page A3-119:

- The architecture does not require a load instruction by another processor, that is not a Load-Exclusive instruction, to have any effect on the global monitor.
- Whether a Store-Exclusive successfully updates memory or not depends on whether the address accessed matches the tagged Shareable memory address for the processor issuing the Store-Exclusive instruction. For this reason, Figure A3-4 on page A3-119 and Table A3-4 only show how the (!n) entries cause state transitions of the state machine for processor(n).
- An Load-Exclusive can only update the tagged Shareable memory address for the processor issuing the Load-Exclusive instruction.
- The effect of the CLREX instruction on the global monitor is IMPLEMENTATION DEFINED.
- It is IMPLEMENTATION DEFINED:
  - whether a modification to a non-shareable memory location can cause a global monitor to transition from Exclusive Access to Open Access state
  - whether a Load-Exclusive to a non-shareable memory location can cause a global monitor to transition from Open Access to Exclusive Access state.

Table A3-4 shows the effect of the operations shown in Figure A3-4 on page A3-119.

Table A3-4 Effect of load/store operations on global monitor for processor(n)

Initial state	Operation[a]	Effect	Final state
Exclusive Access	`LoadExcl(x, n)`	Loads value from memory, tags address x	Exclusive Access
	`CLREX(n)`	None. Effect on the final state is IMPLEMENTATION DEFINED.	Exclusive Access[d]
			Open Access[d]
	`CLREX(!n)`	None	Exclusive Access
	`StoreExcl(t, !n)`	Updates memory, returns status 0[b]	Open Access
		Does not update memory, returns status 1[b]	Exclusive Access
	`StoreExcl(t, n)`	Updates memory, returns status 0[c]	Open Access
			Exclusive Access
	`StoreExcl(!t, n)`	Updates memory, returns status 0[d]	Open Access
			Exclusive Access
		Does not update memory, returns status 1[d]	Open Access
			Exclusive Access
	`StoreExcl(!t, !n)`	Depends on state machine and tag address for processor issuing STREX	Exclusive Access
	`Store(t, n)`	Updates memory	Exclusive Access[d]
			Open Access[d]
	`Store(t, !n)`	Updates memory	Open Access
	`Store(!t, n)`, `Store(!t, !n)`	Updates memory, no effect on monitor	Exclusive Access

Table A3-4 Effect of load/store operations on global monitor for processor(n) (continued)

Initial state	Operation[a]	Effect	Final state
Open Access	`CLREX(n)`, `CLREX(!n)`	None	Open Access
	`StoreExcl(x, n)`	Does not update memory, returns status 1	Open Access
	`LoadExcl(x, !n)`	Loads value from memory, no effect on tag address for processor(n)	Open Access
	`StoreExcl(x, !n)`	Depends on state machine and tag address for processor issuing `STREX`[b]	Open Access
	`Store(x, n)`, `Store(x, !n)`	Updates memory, no effect on monitor	Open Access
	`LoadExcl(x, n)`	Loads value from memory, tags address x	Exclusive Access

a. In the table:

`LoadExcl` represents any Load-Exclusive instruction

`StoreExcl` represents any Store-Exclusive instruction

`Store` represents any store operation other than a Store-Exclusive operation.

t is the tagged address for processor(n), bits[31:a] of the address of the last Load-Exclusive instruction issued by processor(n), see *Tagging and the size of the tagged memory block*.

b. The result of a `STREX(x, !n)` or a `STREX(t, !n)` operation depends on the state machine and tagged address for the processor issuing the `STREX` instruction. This table shows how each possible outcome affects the state machine for processor(n).

c. After a successful `STREX` to the tagged address, the state of the state machine is IMPLEMENTATION DEFINED. However, this state has no effect on the subsequent operation of the global monitor.

d. Effect is IMPLEMENTATION DEFINED. The table shows all permitted implementations.

A3.4.3 Tagging and the size of the tagged memory block

As stated in the footnotes to Table A3-3 on page A3-116 and Table A3-4 on page A3-120, when a Load-Exclusive instruction is executed, the resulting tag address ignores the least significant bits of the memory address.

```
Tagged_address = Memory_address[31:a]
```

The value of a in this assignment is IMPLEMENTATION DEFINED, between a minimum value of 3 and a maximum value of 11. For example, in an implementation where a is 4, a successful `LDREX` of address `0x000341B4` gives a tag value of bits[31:4] of the address, giving `0x000341B`. This means that the four words of memory from `0x000341B0` to `0x000341BF` are tagged for exclusive access.

The size of the tagged memory block is called the *Exclusives Reservation Granule*. The Exclusives Reservation Granule is IMPLEMENTATION DEFINED in the range 2-512 words:

- 2 words in an implementation where a is 3
- 512 words in an implementation where a is 11.

In some implementations the CTR identifies the Exclusives Reservation Granule, see either:

- *CTR, Cache Type Register, VMSA* on page B4-1556
- *CTR, Cache Type Register, PMSA* on page B6-1833.

A3.4.4 Context switch support

After a context switch, software must ensure that the local monitor is in the Open Access state. This requires it to either:

- execute a CLREX instruction
- execute a dummy STREX to a memory address allocated for this purpose.

Note

- Using a dummy STREX for this purpose is backwards-compatible with the ARMv6 implementation of the exclusive operations. The CLREX instruction is introduced in ARMv6K.
- Context switching is not an application level operation. However, this information is included here to complete the description of the exclusive operations.

The STREX or CLREX instruction that follows a context switch might cause a subsequent Store-Exclusive to fail, requiring a Load-Exclusive … Store-Exclusive sequence to be repeated. To minimize the possibility of this happening, ARM recommends that the Store-Exclusive instruction is kept as close as possible to the associated Load-Exclusive instruction, see *Load-Exclusive and Store-Exclusive usage restrictions*.

A3.4.5 Load-Exclusive and Store-Exclusive usage restrictions

The Load-Exclusive and Store-Exclusive instructions are intended to work together, as a pair, for example a LDREX/STREX pair or a LDREXB/STREXB pair. To support different implementations of these functions, software must follow the notes and restrictions given here.

These notes describe use of an LDREX/STREX pair, but apply equally to any other Load-Exclusive/Store-Exclusive pair:

- The exclusives support a single outstanding exclusive access for each processor thread that is executed. The architecture makes use of this by not requiring an address or size check as part of the IsExclusiveLocal() function. If the target virtual address of an STREX is different from the virtual address of the preceding LDREX in the same thread of execution, behavior can be UNPREDICTABLE. As a result, an LDREX/STREX pair can only be relied upon to eventually succeed if they are executed with the same address. Where a context switch or exception might change the thread of execution, a CLREX instruction or a dummy STREX instruction must be executed to avoid unwanted effects, as described in *Context switch support*. Using an STREX in this way is the only occasion where software can program an STREX with a different address from the previously executed LDREX.
- If two STREX instructions are executed without an intervening LDREX the second STREX returns a status value of 1. This means that:
  - ARM recommends that, in a given thread of execution, every STREX has a preceding LDREX associated with it
  - it is not necessary for every LDREX to have a subsequent STREX.
- An implementation of the Load-Exclusive and Store-Exclusive instructions can require that, in any thread of execution, the transaction size of a Store-Exclusive is the same as the transaction size of the preceding Load-Exclusive executed in that thread. If the transaction size of a Store-Exclusive is different from the preceding Load-Exclusive in the same thread of execution, behavior can be UNPREDICTABLE. As a result, software can rely on an LDREX/STREX pair to eventually succeed only if they have the same size. Where a context switch or exception might change the thread of execution, the software must execute a CLREX instruction, or a dummy STREX instruction, to avoid unwanted effects, as described in *Context switch support*. Using an STREX in this way is the only occasion where software can use a Store-Exclusive instruction with a different transaction size from the previously executed Load-Exclusive instruction.
- An implementation might clear an exclusive monitor between the LDREX and the STREX, without any application-related cause. For example, this might happen because of cache evictions. Software written for such an implementation must, in any single thread of execution, avoid having any explicit memory accesses or cache maintenance operations between the LDREX instruction and the associated STREX instruction.

- In some implementations, an access to Strongly-ordered or Device memory might clear the exclusive monitor. Therefore, software must not place a load or a store to Strongly-ordered or Device memory between an LDREX and an STREX in a single thread of execution.
- Implementations can benefit from keeping the LDREX and STREX operations close together in a single thread of execution. This minimizes the likelihood of the exclusive monitor state being cleared between the LDREX instruction and the STREX instruction. Therefore, for best performance, ARM strongly recommends a limit of 128 bytes between LDREX and STREX instructions in a single thread of execution.
- The architecture sets an upper limit of 2048 bytes on the size of a region that can be marked as exclusive. Software can read the implemented size of the Exclusives reservation granule from the CTR.ERG field, see:
  - — *CTR, Cache Type Register, VMSA* on page B4-1556 for a VMSA implementation.
  - — *CTR, Cache Type Register, PMSA* on page B6-1833 for a PMSA implementation.

  In a heavily contended system, having multiple objects that are in the same exclusive reservation granule accessed by exclusive accesses can lead to starvation of a process accessing that granule. Therefore, in such systems, ARM recommends that objects that are accessed by exclusive accesses are separated by the size of the Exclusive Reservation Granule.
- It is IMPLEMENTATION DEFINED whether LDREX and STREX operations can be performed to a memory region with the Device or Strongly-ordered memory attribute. Unless the implementation documentation explicitly states that LDREX and STREX operations to a memory region with the Device or Strongly-ordered attribute are permitted, the effect of such operations is UNPREDICTABLE.
- After taking a Data Abort exception, the state of the exclusive monitors is UNKNOWN. Therefore ARM strongly recommends that the abort handling software performs a CLREX instruction, or a dummy STREX instruction, to clear the monitor state.
- If the memory attributes for the memory being accessed by an LDREX/STREX pair are changed between the LDREX and the STREX, behavior is UNPREDICTABLE.
- The effect of a data or unified cache invalidate instruction on a local or global exclusive monitor that is in the Exclusive Access state is UNPREDICTABLE. The operation might clear the monitor, or it might leave it in the Exclusive Access state. For address-based invalidation this also applies to the monitors of other processors in the same shareability domain as the processor executing the cache invalidation instruction, as determined by the shareability domain of the address being invalidated.

  Note

  ARM strongly recommends that implementations ensure that the use of such maintenance operations by a processor in the Non-secure state cannot cause a denial of service on a processor in the Secure state.

Note

In the event of repeatedly-contending load-exclusive/store-exclusive sequences from multiple processors, an implementation must ensure that forward progress is made by at least one processor.

A3.4.6 Semaphores

The Swap (SWP) and Swap Byte (SWPB) instructions must be used with care to ensure that expected behavior is observed. Two examples are as follows:

1. A system with multiple bus masters that uses Swap instructions to implement semaphores that control interactions between different bus masters.

   In this case, the semaphores must be placed in an uncached region of memory, where any buffering of writes occurs at a point common to all bus masters using the mechanism. The Swap instruction then causes a locked read-write bus transaction.

2. A system with multiple threads running on a uniprocessor that uses Swap instructions to implement semaphores that control interaction of the threads.

In this case, the semaphores can be placed in a cached region of memory, and a locked read-write bus transaction might or might not occur. The Swap and Swap Byte instructions are likely to have better performance on such a system than they do on a system with multiple bus masters, such as that described in example 1.

Note

From ARMv6, ARM deprecates use of the Swap and Swap Byte instructions, and strongly recommends that all new software uses the Load-Exclusive and Store-Exclusive synchronization primitives described in *Synchronization and semaphores* on page A3-114, for example `LDREX` and `STREX`.

A3.4.7 Synchronization primitives and the memory order model

The synchronization primitives follow the memory order model of the memory type accessed by the instructions. For this reason:

- Portable software for claiming a spin-lock must include a *Data Memory Barrier* (DMB) operation, performed by a `DMB` instruction, between claiming the spin-lock and making any access that makes use of the spin-lock.
- Portable software for releasing a spin-lock must include a `DMB` instruction before writing to clear the spin-lock.

This requirement applies to software using:

- the Load-Exclusive/Store-Exclusive instruction pairs, for example `LDREX`/`STREX`
- the deprecated synchronization primitives, `SWP`/`SWPB`.

A3.4.8 Use of WFE and SEV instructions by spin-locks

ARMv7 and ARMv6K provide Wait For Event and Send Event instructions, `WFE` and `SEV`, that can assist with reducing power consumption and bus contention caused by processors repeatedly attempting to obtain a spin-lock. These instructions can be used at the application level, but a complete understanding of what they do depends on system level understanding of exceptions. They are described in *Wait For Event and Send Event* on page B1-1199.

A3.5 Memory types and attributes and the memory order model

ARMv6 defined a set of memory attributes with the characteristics required to support the memory and devices in the system memory map. In ARMv7 this set of attributes is extended by the addition of the Outer Shareable attribute for Normal memory and, in an implementation that does not include the Large Physical Address Extension, for Device memory.

Note

Whether an ARMv7 implementation distinguishes between Inner Shareable and Outer Shareable memory is IMPLEMENTATION DEFINED.

The ordering of accesses for regions of memory, referred to as the memory order model, is defined by the memory attributes. This model is described in the following sections:

- *Memory types*
- *Summary of ARMv7 memory attributes* on page A3-126
- *Atomicity in the ARM architecture* on page A3-127
- *Concurrent modification and execution of instructions* on page A3-129
- *Normal memory* on page A3-131
- *Device and Strongly-ordered memory* on page A3-135
- *Memory access restrictions* on page A3-137
- *The effect of the Security Extensions* on page A3-140.

A3.5.1 Memory types

For each memory region, the most significant memory attribute specifies the memory type. There are three mutually exclusive memory types:

- Normal
- Device
- Strongly-ordered.

Normal and Device memory regions have additional attributes.

Usually, memory used for programs and for data storage is suitable for access using the Normal memory attribute. Examples of memory technologies for which the Normal memory attribute is appropriate are:

- programmed Flash ROM

  Note

  During programming, Flash memory can be ordered more strictly than Normal memory.

- ROM
- SRAM
- DRAM and DDR memory.

System peripherals (I/O) generally conform to different access rules. Examples of I/O accesses are:

- FIFOs where consecutive accesses:
  - add queued values on write accesses
  - remove queued values on read accesses.
- interrupt controller registers where an access can be used as an interrupt acknowledge, changing the state of the controller itself
- memory controller configuration registers that are used for setting up the timing and correctness of areas of Normal memory
- memory-mapped peripherals, where accessing a memory location can cause side-effects in the system.

In ARMv7, the Strongly-ordered or Device memory attribute provides suitable access control for such peripherals. To ensure correct system behavior, the access rules for Device and Strongly-ordered memory are more restrictive than those for Normal memory, so that:

- Neither read nor write accesses can be performed speculatively.

  Note

  However, translation table walks can be made speculatively to memory marked as Device or Strongly-ordered, see *Device and Strongly-ordered memory* on page A3-135.

- Read and write accesses cannot be repeated, for example, on return from an exception.
- The number, order and sizes of the accesses are maintained.

For more information, see *Device and Strongly-ordered memory* on page A3-135.

A3.5.2 Summary of ARMv7 memory attributes

Table A3-5 summarizes the memory attributes. For more information about these attributes see:

- *Normal memory* on page A3-131 and *Shareable attribute for Device memory regions* on page A3-136, for the *shareability* attribute
- *Write-Through Cacheable, Write-Back Cacheable and Non-cacheable Normal memory* on page A3-133, for *cacheability* and *cache allocation hint* attributes.

Note

The cacheability and cache allocation hint attributes apply only to Normal memory. Device and Strongly-ordered memory regions are Non-cacheable.

In this table:

Shareability Applies only to Normal memory, and to Device memory in an implementation that does not include the Large Physical Address Extensions. In an implementation that includes the Large Physical Address Extensions, Device memory is always Outer Shareable,

When it is possible to assign a shareability attribute to Device memory, ARM deprecates assigning any attribute other than Shareable or Outer Shareable, see *Shareable attribute for Device memory regions* on page A3-136

Whether an ARMv7 implementation distinguishes between Inner Shareable and Outer Shareable memory is IMPLEMENTATION DEFINED.

Cacheability Applies only to Normal memory, and can be defined independently for Inner and Outer cache regions. Some cacheability attributes can be complemented by a *cache allocation hint*. This is an indication to the memory system of whether allocating a value to a cache is likely to improve performance. For more information see *Cacheability and cache allocation hint attributes* on page B2-1264.

An implementation might not make any distinction between memory regions with attributes that differ only in their cache allocation hint.

Table A3-5 Memory attribute summary

Memory type	Implementation includes LPAE[a]?	Shareability	Cacheability
Strongly- ordered	-	-	-

Table A3-5 Memory attribute summary (continued)

Memory type	Implementation includes LPAE[a]?	Shareability	Cacheability
Device	Yes	Outer Shareable	-
	No	Outer Shareable	
		Inner Shareable	
		Non-shareable	
Normal	-	Outer Shareable	One of: • Non-cacheable • Write-Through Cacheable • Write-Back Cacheable.
		Inner Shareable	
		Non-shareable	

a. LPAE means the Large Physical Address Extension.

Memory model and memory ordering on page AppxO-2593 compares these attributes with the memory attributes in architecture versions before ARMv6.

A3.5.3 Atomicity in the ARM architecture

Atomicity is a feature of memory accesses, described as *atomic* accesses. The ARM architecture description refers to two types of atomicity, defined in:

- *Single-copy atomicity*
- *Multi-copy atomicity* on page A3-129.

Single-copy atomicity

A read or write operation is *single-copy atomic* if the following conditions are both true:

- After any number of write operations to a memory location, the value of the memory location is the value written by one of the write operations. It is impossible for part of the value of the memory location to come from one write operation and another part of the value to come from a different write operation.
- When a read operation and a write operation are made to the same memory location, the value obtained by the read operation is one of:
  - the value of the memory location before the write operation
  - the value of the memory location after the write operation.

  It is never the case that the value of the read operation is partly the value of the memory location before the write operation and partly the value of the memory location after the write operation.

In ARMv7, the single-copy atomic processor accesses are:

- all byte accesses
- all halfword accesses to halfword-aligned locations
- all word accesses to word-aligned locations
- memory accesses caused by `LDREXD` and `STREXD` instructions to doubleword-aligned locations.

`LDM`, `LDC`, `LDC2`, `LDRD`, `STM`, `STC`, `STC2`, `STRD`, `PUSH`, `POP`, `RFE`, `SRS`, `VLDM`, `VLDR`, `VSTM`, and `VSTR` instructions are executed as a sequence of word-aligned word accesses. Each 32-bit word access is guaranteed to be single-copy atomic. The architecture does not require subsequences of two or more word accesses from the sequence to be single-copy atomic.

In an implementation that includes the Large Physical Address Extension, LDRD and STRD accesses to 64-bit aligned locations are 64-bit single-copy atomic as seen by translation table walks and accesses to translation tables.

Note

The Large Physical Address Extension adds this requirement to avoid the need for complex measures to avoid atomicity issues when changing translation table entries, without creating a requirement that all locations in the memory system are 64-bit single-copy atomic. This addition means:

- The system designer must ensure that all writable memory locations that might be used to hold translations, such as bulk SDRAM, can be accessed with 64-bit single-copy atomicity.
- Software must ensure that translation tables are not held in memory locations that cannot meet this atomicity requirement, such as peripherals that are typically accessed using a narrow bus.

This requirement places no burden on read-only memory locations for which reads have no side effects, since it is impossible to detect the size of memory accesses to such locations.

Advanced SIMD element and structure loads and stores are executed as a sequence of accesses of the element or structure size. The architecture requires the element accesses to be single-copy atomic if and only if both:

- the element size is 32 bits, or smaller
- the elements are naturally aligned.

Accesses to 64-bit elements or structures that are at least word-aligned are executed as a sequence of 32-bit accesses, each of which is single-copy atomic.The architecture does not require subsequences of two or more 32-bit accesses from the sequence to be single-copy atomic.

When a store that, by the rules given in this section, would be single-copy atomic is made to a memory location at a time when there is at least one store to the same memory location that has not completed and that would be single-copy atomic at a different size, then the architecture does not give any assurance of atomicity between accesses to the bytes of that location.

When an access is not single-copy atomic, it is executed as a sequence of smaller accesses, each of which is single-copy atomic, at least at the byte level.

Note

In this section, the terms *before the write operation* and *after the write operation* mean before or after the write operation has had its effect on the coherence order of the bytes of the memory location accessed by the write operation.

If, according to these rules, an instruction is executed as a sequence of accesses, some exceptions can be taken during that sequence. Such an exception causes execution of the instruction to be abandoned. These exceptions are:

- Synchronous Data Abort exceptions.
- The following, if low interrupt latency configuration is selected and the accesses are to Normal memory:
  - IRQ interrupts
  - FIQ interrupts
  - asynchronous aborts.

  For more information about this configuration, see *Low interrupt latency configuration* on page B1-1197.

If any of these exceptions are returned from using their preferred return address, the instruction that generated the sequence of accesses is re-executed and so any access that had been performed before the exception was taken is repeated.

Note

The exception behavior for these multiple access instructions means they are not suitable for use for writes to memory for the purpose of software synchronization.

For implicit accesses:

- Cache linefills and evictions have no effect on the single-copy atomicity of explicit transactions or instruction fetches.
- Instruction fetches are single-copy atomic:
  - at 32-bit granularity in ARM state
  - at 16-bit granularity in Thumb and ThumbEE states
  - at 8-bit granularity in Jazelle state.

  Concurrent modification and execution of instructions describes additional constraints on the behavior of instruction fetches.
- Translation table walks are performed using accesses that are single-copy atomic:
  - at 32-bit granularity when using Short-descriptor format translation tables
  - at 64-bit granularity when using Long-descriptor format translation tables.

Multi-copy atomicity

In a multiprocessing system, writes to a memory location are *multi-copy atomic* if the following conditions are both true:

- All writes to the same location are *serialized*, meaning they are observed in the same order by all observers, although some observers might not observe all of the writes.
- A read of a location does not return the value of a write until all observers observe that write.

Writes to Normal memory are not multi-copy atomic.

All writes to Device and Strongly-ordered memory that are single-copy atomic are also multi-copy atomic.

All write accesses to the same location are serialized. Write accesses to Normal memory can be repeated up to the point that another write to the same address is observed.

For Normal memory, serialization of writes does not prohibit the merging of writes.

A3.5.4 Concurrent modification and execution of instructions

The ARMv7 architecture limits the set of instructions that can be executed by one thread of execution as they are being modified by another thread of execution without requiring explicit synchronization.

Except for the instructions identified in this section, the effect of the concurrent modification and execution of an instruction is UNPREDICTABLE.

For the following instructions only, the architecture guarantees that, after modification of the instruction, behavior is consistent with execution of either:

- The instruction originally fetched.
- A fetch of the new instruction. That is, a fetch of the instruction that results from the modification.

The instructions to which this guarantee applies are:

In the Thumb instruction set

The 16-bit encodings of the `B`, `NOP`, `BKPT`, and `SVC` instructions.

In addition:

- The most-significant halfword of a `BL` instruction can be concurrently modified to the most significant halfword of another `BL` instruction.

  The most-significant halfword of a `BLX` instruction can be concurrently modified to the most significant halfword of another `BLX` instruction.

  These cases mean that the most significant bits of the immediate value can be modified.
- The most-significant halfword of a `BL` or `BLX` instruction can be concurrently modified to a 16-bit `B`, `BKPT`, or `SVC` instruction.

- The least-significant halfword of a BL instruction can be concurrently modified to the least significant halfword of another BL instruction.

  The least-significant halfword of a BLX instruction can be concurrently modified to the least significant halfword of another BLX instruction.

  These cases mean that the least significant bits of the immediate value can be modified.
- The least-significant halfword of a 32-bit B immediate instruction:
  - with a condition field can be concurrently modified to the least significant halfword of another 32-bit B immediate instruction with a condition field
  - without a condition field can be concurrently modified to the least significant halfword of another 32-bit B immediate instruction without a condition field.

  These cases mean that the least significant bits of the immediate value can be modified.
- A 16-bit B, BKPT, or SVC instruction can be concurrently modified to the most-significant halfword of a BL instruction.

Note

In the Thumb instruction set:
- the only encodings of BKPT and SVC are 16-bit
- the only encoding of BL is 32-bit.

In the ARM instruction set

The B, BL, NOP, BKPT, SVC, HVC, and SMC instructions.

For all other instructions, to avoid UNPREDICTABLE behavior, instruction modifications must be explicitly synchronized before they are executed. The required synchronization is as follows:

1. To ensure that the modified instructions are observable, the thread of execution that is modifying the instructions must issue the following sequence of instructions and operations:

```
DCCMVAU [instruction location]  ; Clean data cache by MVA to point of unification
   DSB                          ; Ensure visibility of the data cleaned from the cache
   ICIMVAU [instruction location]  ; Invalidate instruction cache by MVA to PoU
   BPIMVAU [instruction location]  ; Invalidate branch predictor by MVA to PoU
   DSB                          ; Ensure completion of the invalidations
```

2. Once the modified instructions are observable, the thread of execution that is executing the modified instructions must issue the following instructions or operations to ensure execution of the modified instructions:

```
ISB                          ; Synchronize fetched instruction stream
```

Note

Issue C.a of this manual first describes this behavior, but the description applies to all ARMv7 implementations.

In addition, for both instruction sets, if one thread of execution changes a conditional branch instruction to another conditional branch instruction, and the change affects both the condition field and the branch target, execution of the changed instruction by another thread of execution before the change is synchronized can lead to either:
- the old condition being associated with the new target address
- the new condition being associated with the old target address.

These possibilities apply regardless of whether the condition, either before or after the change to the branch instruction, is the always condition.

A3.5.5 Normal memory

Accesses to normal memory region are idempotent, meaning that they exhibit the following properties:

- read accesses can be repeated with no side-effects
- repeated read accesses return the last value written to the resource being read
- read accesses can fetch additional memory locations with no side-effects
- write accesses can be repeated with no side-effects in the following cases:
  - if the contents of the location accessed are unchanged between the repeated writes
  - as the result of an exception, as described in this section
- unaligned accesses can be supported
- accesses can be merged before accessing the target memory system.

Normal memory can be read/write or read-only, and a Normal memory region is defined as being either Shareable or Non-shareable. For Shareable Normal memory, whether a VMSA implementation distinguishes between Inner Shareable and Outer Shareable is IMPLEMENTATION DEFINED. A PMSA implementation makes no distinction between Inner Shareable and Outer Shareable regions.

The Normal memory type attribute applies to most memory used in a system.

Accesses to Normal Memory have a weakly consistent model of memory ordering. See a standard text describing memory ordering issues for a description of weakly consistent memory models, for example chapter 2 of *Memory Consistency Models for Shared Memory-Multiprocessors*. In general, for Normal memory, barrier operations are required where the order of memory accesses observed by other observers must be controlled. This requirement applies regardless of the cacheability and shareability attributes of the Normal memory region.

The ordering requirements of accesses described in *Ordering requirements for memory accesses* on page A3-148 apply to all explicit accesses.

An instruction that generates a sequence of accesses as described in *Atomicity in the ARM architecture* on page A3-127 might be abandoned as a result of an exception being taken during the sequence of accesses. On return from the exception the instruction is restarted, and therefore one or more of the memory locations might be accessed multiple times. This can result in repeated write accesses to a location that has been changed between the write accesses.

The architecture permits speculative accesses to memory locations marked as Normal if the access permissions and domain permit an access to the locations.

A Normal memory region has shareability attributes that define the data coherency properties of the region. These attributes do not affect the coherency requirements of:

- Instruction fetches, see *Instruction coherency issues* on page A3-157.
- Translation table walks for VMSA implementations of:
  - ARMv7-A without the Multiprocessing extensions
  - versions of the architecture before ARMv7.

  For more information, see *TLB maintenance operations and the memory order model* on page B3-1383.

Non-shareable Normal memory

For a Normal memory region, the Non-shareable attribute identifies Normal memory that is likely to be accessed only by a single processor.

A region of Normal memory with the Non-shareable attribute does not have any requirement to make data accesses by different observers coherent, unless the memory is Non-cacheable. If other observers share the memory system, software must use cache maintenance operations if the presence of caches might lead to coherency issues when communicating between the observers. This cache maintenance requirement is in addition to the barrier operations that are required to ensure memory ordering.

For Non-shareable Normal memory, it is IMPLEMENTATION DEFINED whether the Load-Exclusive and Store-Exclusive synchronization primitives take account of the possibility of accesses by more than one observer.

Shareable, Inner Shareable, and Outer Shareable Normal memory

For Normal memory, the Shareable and Outer Shareable memory attributes describe Normal memory that is expected to be accessed by multiple processors or other system masters:

- In a VMSA implementation, Normal memory that has the Shareable attribute but not the Outer Shareable attribute assigned is described as having the Inner Shareable attribute.
- In a PMSA implementation, no distinction is made between Inner Shareable and Outer Shareable Normal memory.

A region of Normal memory with the Shareable attribute is one for which data accesses to memory by different observers within the same shareability domain are coherent.

The Outer Shareable attribute is introduced in ARMv7, and can be applied only to a Normal memory region in a VMSA implementation that has the Shareable attribute assigned. It creates three levels of shareability for a Normal memory region:

Non-shareable A Normal memory region that does not have the Shareable attribute assigned.

Inner Shareable A Normal memory region that has the Shareable attribute assigned, but not the Outer Shareable attribute.

Outer Shareable A Normal memory region that has both the Shareable and the Outer Shareable attributes assigned.

These attributes can define sets of observers for which the shareability attributes make the data or unified caches transparent for data accesses. The sets of observers that are affected by the shareability attributes are described as *shareability domains*. The details of the use of these attributes are system-specific. Example A3-1 shows how they might be used:

Example A3-1 Use of shareability attributes

In a VMSA implementation, a particular subsystem with two clusters of processors has the requirement that:

- in each cluster, the data or unified caches of the processors in the cluster are transparent for all data accesses with the Inner Shareable attribute
- however, between the two clusters, the caches:
  - are not transparent for data accesses that have only the Inner Shareable attribute
  - are transparent for data accesses that have the Outer Shareable attribute.

In this system, each cluster is in a different shareability domain for the Inner Shareable attribute, but all components of the subsystem are in the same shareability domain for the Outer Shareable attribute.

A system might implement two such subsystems. If the data or unified caches of one subsystem are not transparent to the accesses from the other subsystem, this system has two Outer Shareable shareability domains.

However, for a Normal memory region that is Non-cacheable, as described in *Write-Through Cacheable, Write-Back Cacheable and Non-cacheable Normal memory* on page A3-133, the only significance of the Shareability attribute is the behavior of Load-Exclusive and Store-Exclusive instructions. For more information about this behavior see *Synchronization and semaphores* on page A3-114.

Having two levels of shareability attribute means system designers can reduce the performance and power overhead for shared memory regions that do not need to be part of the Outer Shareable shareability domain.

In a VMSA implementation, for Shareable Normal memory, whether there is a distinction between Inner Shareable and Outer Shareable is IMPLEMENTATION DEFINED.

For Shareable Normal memory, the Load-Exclusive and Store-Exclusive synchronization primitives take account of the possibility of accesses by more than one observer in the same Shareability domain.

Note

- System designers can use the Shareable concept to specify the locations in Normal memory that must have coherency requirements. However, to facilitate porting of software, software developers must not assume that specifying a memory region as Non-shareable permits software to make assumptions about the incoherency of memory locations between different processors in a shared memory system. Such assumptions are not portable between different multiprocessing implementations that make use of the Shareable concept. Any multiprocessing implementation might implement caches that, inherently, are shared between different processing elements.
- This architecture is written with an expectation that all processors using the same operating system or hypervisor are in the same Inner Shareable shareability domain.

Write-Through Cacheable, Write-Back Cacheable and Non-cacheable Normal memory

In addition to being Outer Shareable, Inner Shareable or Non-shareable, each region of Normal memory is assigned a cacheability attribute that is one of:

- Write-Through Cacheable
- Write-Back Cacheable
- Non-cacheable.

Also, for cacheable Normal memory regions:

- a region might be assigned a cache allocation hint
- in an ARMv7-A implementation that includes the Large Physical Address Extension, it is IMPLEMENTATION DEFINED whether the Write-Through Cacheable and Write-Back Cacheable attributes can have an additional attribute of Transient or Non-transient, see *Transient cacheability attribute, Large Physical Address Extension* on page A3-134.

A memory location can be marked as having different cacheability attributes, for example when using aliases in a virtual to physical address mapping:

- if the attributes differ only in the cache allocation hint this does not affect the behavior of accesses to that location
- for other cases see *Mismatched memory attributes* on page A3-138.

The cacheability attributes provide a mechanism of coherency control with observers that lie outside the shareability domain of a region of memory. In some cases, the use of Write-Through Cacheable or Non-cacheable regions of memory might provide a better mechanism for controlling coherency than the use of hardware coherency mechanisms or the use of cache maintenance routines. To this end, the architecture requires the following properties for Non-cacheable or Write-Through Cacheable memory:

- a completed write to a memory location that is Non-cacheable or Write-Through Cacheable for a level of cache made by an observer accessing the memory system inside the level of cache is visible to all observers accessing the memory system outside the level of cache without the need of explicit cache maintenance
- a completed write to a memory location that is Non-cacheable for a level of cache made by an observer accessing the memory system outside the level of cache is visible to all observers accessing the memory system inside the level of cache without the need of explicit cache maintenance.

Note

Implementations can use the cache allocation hints to indicate a probable performance benefit of caching. For example, a programmer might know that a piece of memory is not going to be accessed again and would be better treated as Non-cacheable. The distinction between memory regions with attributes that differ only in the cache allocation hints exists only as a hint for performance.

The ARM architecture provides independent cacheability attributes for Normal memory for two conceptual levels of cache, the *inner* and the *outer* cache. The relationship between these conceptual levels of cache and the implemented physical levels of cache is IMPLEMENTATION DEFINED, and can differ from the boundaries between the Inner and Outer Shareability domains. However:

- inner refers to the innermost caches, and always includes the lowest level of cache
- no cache controlled by the Inner cacheability attributes can lie outside a cache controlled by the Outer cacheability attributes
- an implementation might not have any outer cache.

Example A3-2, Example A3-3, and Example A3-4 describe the possible ways of implementing a system with three levels of cache, *level 1* (L1) to *level 3* (L3).

Note

- L1 cache is the level closest to the processor, see *Memory hierarchy* on page A3-155.
- When managing coherency, system designs must consider both the inner and outer cacheability attributes, as well as the shareability attributes. This is because hardware might have to manage the coherency of caches at one conceptual level, even when another conceptual level has the Non-cacheable attribute.

Example A3-2 Implementation with two inner and one outer cache levels

Implement the three levels of cache in the system, L1 to L3, with:

- the Inner cacheability attribute applied to L1 and L2 cache
- the Outer cacheability attribute applied to L3 cache.

Example A3-3 Implementation with three inner and no outer cache levels

Implement the three levels of cache in the system, L1 to L3, with the Inner cacheability attribute applied to L1, L2, and L3 cache. Do not use the Outer cacheability attribute.

Example A3-4 Implementation with one inner and two outer cache levels

Implement the three levels of cache in the system, L1 to L3, with:

- the Inner cacheability attribute applied to L1 cache
- the Outer cacheability attribute applied to L2 and L3 cache.

Transient cacheability attribute, Large Physical Address Extension

For an ARMv7-A implementation that includes the Large Physical Address Extension, it is IMPLEMENTATION DEFINED whether a Transient attribute is supported for cacheable Normal memory regions. If an implementation supports this attribute, the set of possible cacheability attributes for a Normal memory region becomes:

- Write-Through Cacheable, Non-transient
- Write-Back Cacheable, Non-transient
- Write-Through Cacheable, Transient
- Write-Back Cacheable, Transient
- Non-cacheable.

The cacheability attribute can be defined independently for the inner and outer levels of caching.

The transient attribute indicates that the benefit of caching is for a relatively short period, and that therefore it might be better to restrict allocation, to avoid possibly casting-out other, less transient, entries.

Note

The architecture does not specify what is meant by a *relatively short period*.

The description of the MAIR*n* registers includes the assignment of the Transient attribute in an implementation that supports this option.

A3.5.6 Device and Strongly-ordered memory

The Device and Strongly-ordered memory type attributes define memory locations where an access to the location can cause side-effects, or where the value returned for a load can vary depending on the number of loads performed. In ARMv7, Device and Strongly-ordered memory differ only in their shareability options, as this section describes.

Note

See *Ordering of instructions that change the CPSR interrupt masks* on page AppxL-2506 for additional requirements that apply to accesses to Strongly-ordered memory in ARMv6.

Examples of memory regions normally marked as being Device or Strongly-ordered memory are Memory-mapped peripherals and I/O locations.

For explicit accesses from the processor to memory marked as Device or Strongly-ordered:

- all accesses occur at their program size
- the number of accesses is the number specified by the program.

An implementation must not perform more accesses to a Device or Strongly-ordered memory location than are specified by a simple sequential execution of the program, except as a result of an exception. This section describes this permitted effect of an exception.

The architecture does not permit speculative data accesses to memory marked as Device or Strongly-ordered. However, it does not prohibit speculative translation table walks to Device or Strongly-ordered memory.

Note

- For an implementation that includes the Virtualization Extensions, for accesses from an application running in Non-secure state, a speculative translation table walk to Device or Strongly-ordered memory might result from the second stage of address translation defined by a hypervisor. For more information, see *Overlaying the memory type attribute* on page B3-1376.
- For information about restrictions on speculative instruction fetching see:
  - *Execute-never restrictions on instruction fetching* on page B3-1359 for a VMSA implementation
  - *The XN (Execute-never) attribute and instruction fetching* on page B5-1759 for a PMSA implementation.

The architecture permits an Advanced SIMD element or structure load instruction to access bytes in Device or Strongly-ordered memory that are not explicitly accessed by the instruction, provided the bytes accessed are in a 16-byte window, aligned to 16-bytes, that contains at least one byte that is explicitly accessed by the instruction.

Address locations marked as Device or Strongly-ordered are never held in a cache.

Address locations marked as Strongly-ordered, and on an implementation that includes the Large Physical Address Extension, address locations marked as Device, are always treated as Shareable. For more information about the effect of the Large Physical Address Extension on the shareability of these locations see *Device and Strongly-ordered memory shareability, Large Physical Address Extension* on page A3-137.

On an implementation that does not include the Large Physical Address Extension, the shareability of an address location marked as Device is configurable, as described in *Shareable attribute for Device memory regions* on page A3-136.

All explicit accesses to Device or Strongly-ordered memory must comply with the ordering requirements of accesses described in *Ordering requirements for memory accesses* on page A3-148. On an implementation that does not include the Large Physical Address Extension, the requirements for Device memory depend on the shareability of the Device memory locations.

An instruction that generates a sequence of accesses as described in *Atomicity in the ARM architecture* on page A3-127 might be abandoned as a result of an exception being taken during the sequence of accesses. On return from the exception the instruction is restarted, and therefore one or more of the memory locations might be accessed multiple times. This can result in repeated write accesses to a location that has been changed between the write accesses.

Note

Software must not use an instruction that generates a sequence of accesses to access Device or Strongly-ordered memory if the instruction might generate a synchronous Data Abort exception on any access other than the first one.

The only architecturally-required difference between Device and Strongly-ordered memory is that:

- a write to Strongly-ordered memory can complete only when it reaches the peripheral or memory component accessed by the write
- a write to Device memory is permitted to complete before it reaches the peripheral or memory component accessed by the write.

Note

In addition, as described in *Shareable attribute for Device memory regions*, in an implementation that does not include the Large Physical Address Extension, Device memory has Shareability attributes, the interpretation of which is IMPLEMENTATION DEFINED, and might mean a Device memory region is not shareable.

The architecture does not permit unaligned accesses to Strongly-ordered or Device memory. *Memory access restrictions* on page A3-137 summarizes the behavior of such accesses.

Shareable attribute for Device memory regions

In an implementation that does not include the Large Physical Address Extension, Device memory regions can be given the Shareable attribute. When a Device memory region is give the Shareable attribute it can also be given the Outer Shareable attribute. This means that a region of Device memory can be described as one of:

- Outer Shareable Device memory
- Inner Shareable Device memory
- Non-shareable Device memory.

Some implementations make no distinction between Outer Shareable Device memory and Inner Shareable Device memory, and refer to both memory types as Shareable Device memory.

Some implementations make no distinction between Shareable Device memory and Non-shareable Device memory, and refer to both memory types as Shareable Device memory.

For Device memory regions, the significance of shareability is IMPLEMENTATION DEFINED. However, an example of a system supporting Shareable and Non-shareable Device memory is an implementation that supports both:

- a local bus for its private peripherals
- system peripherals implemented on the main shared system bus.

Such a system might have more predictable access times for local peripherals such as watchdog timers or interrupt controllers. In particular, a specific address in a Non-shareable Device memory region might access a different physical peripheral for each processor.

ARM deprecates the marking of Device memory with a shareability attribute other than Outer Shareable or Shareable. This means ARM strongly recommends that Device memory is never assigned a shareability attribute of Non-shareable or Inner Shareable.

Device and Strongly-ordered memory shareability, Large Physical Address Extension

In an implementation that includes the Large Physical Address Extension, the Long-descriptor translation table format does not distinguish between Shareable and Non-shareable Device memory.

In an implementation that includes the Large Physical Address Extension and is using the Short-descriptor translation table format:

- An address-based cache maintenance operation for an addresses in a region with the Strongly-ordered or Device memory type applies to all processors in the same Outer Shareable domain, regardless of any shareability attributes applied to the region.
- Device memory transactions to a single peripheral must not be reordered, regardless of any shareability attributes that are applied to the corresponding Device memory region.

  Any single peripheral has an IMPLEMENTATION DEFINED size of not less than 1KB.

A3.5.7 Memory access restrictions

The following restrictions apply to memory accesses:

- For accesses to any two bytes, *p* and *q*, that are generated by the same instruction:
  - The bytes *p* and *q* must have the same memory type and shareability attributes, otherwise the results are UNPREDICTABLE. For example, an `LDC`, `LDM`, `LDRD`, `STC`, `STM`, `STRD`, or unaligned load or store that spans a boundary between Normal and Device memory is UNPREDICTABLE.
  - Except for possible differences in the cache allocation hints, ARM deprecates having different cacheability attributes for the bytes *p* and *q*.
- *Unaligned data access* on page A3-108 identifies the instructions that can make an unaligned memory access, and the required configuration setting. If such an access is to Device or Strongly-ordered memory then:
  - if the implementation does not include the Large Physical Address Extension, the effect is UNPREDICTABLE
  - if the implementation includes the Large Physical Address Extension, the access generates an Alignment fault.
- An instruction that causes multiple accesses to Device or Strongly-ordered memory must not cross a 4KB address boundary, otherwise the effect is UNPREDICTABLE. For this reason, it is important that an access to a volatile memory device is not made using a single instruction that crosses a 4KB address boundary.

  ARM expects this restriction to impose constraints on the placing of volatile memory devices in the memory map of a system, rather than expecting a compiler to be aware of the alignment of memory accesses.
- For any instruction that generates accesses to Device or Strongly-ordered memory, implementations must not change the sequence of accesses specified by the pseudocode of the instruction. This includes not changing:
  - how many accesses there are
  - the time order of the accesses at any particular memory-mapped peripheral
  - the data size and other properties of each access.

  In addition, processor implementations expect any attached memory system to be able to identify the memory type of accesses, and to obey similar restrictions with regard to the number, time order, data sizes and other properties of the accesses.

  Exceptions to this rule are:
  - An implementation of a processor can break this rule, provided that the original number, time order, and other details of the accesses can be reconstructed from the information it supplies to the memory system. In addition, the implementation must place a requirement on attached memory systems to do this reconstruction when the accesses are to Device or Strongly-ordered memory.

For example, an implementation with a 64-bit bus might pair the word loads generated by an `LDM` into 64-bit accesses. This is because the instruction semantics ensure that the 64-bit access is always a word load from the lower address followed by a word load from the higher address. However the implementation must permit the memory systems to unpack the two word loads when the access is to Device or Strongly-ordered memory.

— An Advanced SIMD element or structure load instruction can access bytes in Device or Strongly-ordered memory that are not explicitly accessed by the instruction, provided the bytes accessed are within a 16-byte window, aligned to 16-bytes, that contains at least one byte that is explicitly accessed by the instruction.

— There is no requirement for the memory system to be able to identify the size of the elements accessed by an Advanced SIMD element or structure load/store instruction.

- In a PMSA implementation, and in a VMSA implementation when any associated MMU is enabled, any multi-access instruction that loads or stores the PC must access only Normal memory. If the instruction accesses Device or Strongly-ordered memory the result is UNPREDICTABLE.
- Any instruction fetch must access only Normal memory. If it accesses Device or Strongly-ordered memory, the result is UNPREDICTABLE.
- If a single physical memory location has more than one set of attributes assigned to it, ARM strongly recommends that software ensures that the sets of attributes are identical. For more information see *Mismatched memory attributes*.

  An example of where multiple sets of attributes might be assigned to the same physical memory location is the use of aliases in a virtual to physical address mapping.

Mismatched memory attributes

A physical memory location is accessed with *mismatched attributes* if all accesses to the location do not use a common definition of all of the following attributes of that location:

- memory type, Strongly-ordered, Device, or Normal
- shareability
- cacheability, for both the inner and outer levels of cache, but excluding any cache allocation hints.

The following rules apply when a physical memory location is accessed with mismatched attributes:

1. When a memory location is accessed with mismatched attributes the only software visible effects are one or more of the following:
   - Uniprocessor semantics for reads and writes to that memory location might be lost. This means:
     — a read of the memory location by a thread of execution might not return the value most recently written to that memory location by that thread of execution
     — multiple writes to the memory location by a thread of execution, that use different memory attributes, might not be ordered in program order.
   - There might be a loss of coherency when multiple threads of execution attempt to access a memory location.
   - There might be a loss of properties derived from the memory type, see rule 2.
   - If multiple threads of execution attempt to use Load-Exclusive or Store-Exclusive instructions to access a location with different memory attributes, the exclusive monitor state becomes UNKNOWN.
2. The loss of properties associated with mismatched memory type attributes refers only to the following properties of Strongly-ordered or Device memory, that are additional to the properties of Normal memory:
   - prohibition of speculative accesses
   - preservation of the size of accesses
   - preservation of the order of accesses
   - the guarantee that the write acknowledgement comes from the endpoint of the access.

If the only memory type mismatch is between Strongly-ordered and Device memory, then the only property that can be lost is:

- the guarantee that the write acknowledgement comes from the endpoint of the access.

3. If all aliases of a memory location that permit write access to the location assign the same shareability and cacheability attributes to that location, and all these aliases use a definition of the shareability attribute that includes all the threads of execution that can access the location, then any thread of execution that reads the memory location using these shareability and cacheability attributes accesses it coherently, to the extent required by that common definition of the memory attributes.

4. The possible loss of properties caused by mismatched attributes for a memory location are defined more precisely if all of the mismatched attributes define the memory location as one of:
   - Strongly-ordered memory
   - Device memory
   - Normal Inner Non-cacheable, Outer Non-cacheable memory.

   In these cases, the only possible software-visible effects of the mismatched attributes are one or more of:
   - possible loss of properties derived from the memory type when multiple threads of execution attempt to access the memory location.
   - possible re-ordering of memory transactions to the memory location that use different memory attributes, potentially leading to a loss of coherency or uniprocessor semantics. Any possible loss of coherency or uniprocessor semantics can be avoided by inserting `DMB` barrier instructions between accesses to the same memory location that might use different attributes.

5. If the mismatched attributes for a memory location all assign the same shareability attribute to the location, any loss of coherency within a shareability domain can be avoided. To do so, software must use the techniques that are required for the software management of the coherency of cacheable locations between threads of execution in different shareability domains. This means:
   - If any thread of execution might have written to the location with the write-back attribute, before writing to the location not using the write-back attribute, a thread of execution must invalidate, or clean, the location from the caches. This avoids the possibility of overwriting the location with stale data.
   - After writing to the location with the write-back attribute, a thread of execution must clean the location from the caches, to make the write visible to external memory.
   - Before reading the location with a cacheable attribute, a thread of execution must invalidate the location from the caches, to ensure that any value held in the caches reflects the last value made visible in external memory.

   In all cases:
   - location refers to any byte within the current coherency granule
   - a clean and invalidate operation can be used instead of a clean operation, or instead of an invalidate operation
   - to ensure coherency, all cache maintenance and memory transactions must be completed, or ordered by the use of barrier operations.

   Note

   With software management of coherency, race conditions can cause loss of data. A race condition occurs when different threads of execution write simultaneously to bytes that are in the same location, and the (invalidate or clean), write, clean sequence of one thread overlaps the equivalent sequence of another thread.

6. If the mismatched attributes for a location mean that multiple cacheable accesses to the location might be made with different shareability attributes, then coherency is guaranteed only if each thread of execution that accesses the location with a cacheable attribute performs a clean and invalidate of the location.

   Note

   The Note in rule 5, about possible race conditions, also applies to this rule.

In addition, if multiple threads attempt to use Load-Exclusive or Store-Exclusive instructions to access a location with different memory attributes associated with it, the exclusive monitor state becomes UNKNOWN.

ARM strongly recommends that software does not use mismatched attributes for aliases of the same location. An implementation might not optimize the performance of a system that uses mismatched aliases.

A3.5.8 The effect of the Security Extensions

The Security Extensions can be included as part of an ARMv7-A implementation, with a VMSA. They provide two distinct 4GByte virtual memory spaces:

- a Secure virtual memory space
- a Non-secure virtual memory space.

The Secure virtual memory space is accessed by memory accesses in the Secure state, and the Non-secure virtual memory space is accessed by memory accesses in the Non-secure state.

By providing different virtual memory spaces, the Security Extensions permit memory accesses made from the Non-secure state to be distinguished from those made from the Secure state.

A3.6 Access rights

ARMv7 defines additional memory region attributes, that define access permissions that can:

- Restrict data accesses, based on the privilege level of the access. See *Privilege level access controls for data accesses* on page A3-142.
- Restrict instruction fetches, based on the privilege level of the process or thread making the fetch. See *Privilege level access controls for instruction accesses* on page A3-142.
- On a system that implements the Security Extensions, restrict accesses so that only memory accesses with the Secure memory attribute are permitted. See *Memory region security status* on page A3-143.

These attributes are defined:

- In a VMSA implementation, in the MMU, see *Memory access control* on page B3-1356, *Memory region attributes* on page B3-1366, and *The effects of disabling MMUs on VMSA behavior* on page B3-1314.
- In a PMSA implementation, in the MPU, see *Memory access control* on page B5-1759 and *Memory region attributes* on page B5-1760.

A3.6.1 Processor privilege levels, execution privilege, and access privilege

As introduced in *About the Application level programmers' model* on page A2-38, within a security state, the ARMv7 architecture defines different levels of *execution privilege*:

- in Secure state, the privilege levels are PL1 and PL0
- in Non-secure state, the privilege levels are PL2, PL1, and PL0.

PL0 indicates unprivileged execution in the current security state.

The current processor mode determines the execution privilege level, and therefore the execution privilege level can be described as the *processor privilege* level.

Every memory access has an *access privilege*, that is either unprivileged or privileged.

The characteristics of the privilege levels are:

PL0 The privilege level of application software, that executes in User mode. Therefore, software executed in User mode is described as unprivileged software. This software cannot access some features of the architecture. In particular, it cannot change many of the configuration settings.

Software executing at PL0 makes only unprivileged memory accesses.

PL1 Software execution in all modes other than User mode and Hyp mode is at PL1. Normally, operating system software executes at PL1. Software executing at PL1 can access all features of the architecture, and can change the configuration settings for those features, except for some features added by the Virtualization Extensions that are only accessible at PL2.

Note

In many implementation models, system software is unaware of the PL2 level of privilege, and of whether the implementation includes the Virtualization Extensions.

The *PL1 modes* refers to all the modes other than User mode and Hyp mode.

Software executing at PL1 makes privileged memory accesses by default, but can also make unprivileged accesses.

PL2 Software executing in Hyp mode executes at PL2.

Software executing at PL2 can perform all of the operations accessible at PL1, and can access some additional functionality.

Hyp mode is normally used by a hypervisor, that controls, and can switch between, Guest OSs, that execute at PL1.

Hyp mode is implemented only as part of the Virtualization Extensions, and only in Non-secure state. This means that:

- implementations that do not include the Virtualization Extensions have only two privilege levels, PL0 and PL1
- execution in Secure state has only two privilege levels, PL0 and PL1.

In an implementation that includes the Security Extensions, the execution privilege levels are defined independently in each security state, and there is no relationship between the Secure and Non-secure privilege levels.

Note

The fact that Non-secure Hyp mode executes at PL2 does not indicate that it is more privileged than the Secure PL1 modes. Secure PL1 modes can change the configuration and control settings for Non-secure operation in all modes, but Non-secure modes can never change the configuration and control settings for Secure operation.

Memory access permissions can be assigned:

- at PL1, for accesses made at PL1 and at PL0
- in Non-secure state, at PL2, independently for:
  - Non-secure accesses made at PL2
  - Non-secure accesses made at PL1, and at PL0.

A3.6.2 Privilege level access controls for data accesses

The memory access permissions assigned at PL1 can define that a memory region is:

- Not accessible to any accesses.
- Accessible only to accesses at PL1.
- Accessible to accesses at any level of privilege.

In Non-secure state, separate memory access permissions can be assigned at PL2 for:

- Accesses made at PL1 and PL0.
- Accesses made at PL2.

The access privilege level is defined separately for explicit read and explicit write accesses. However, a system that specifies the memory attributes is not required to support all combinations of memory attributes for read and write accesses.

A privileged memory access is an access made during execution at PL1 or higher, as a result of a load or store operation other than `LDRT`, `STRT`, `LDRBT`, `STRBT`, `LDRHT`, `STRHT`, `LDRSHT`, or `LDRSBT`.

An unprivileged memory access is an access made as a result of load or store operation performed in one of these cases:

- When the processor is at PL0.
- When the processor is at PL1, and the access is made as a result of a `LDRT`, `STRT`, `LDRBT`, `STRBT`, `LDRHT`, `STRHT`, `LDRSHT`, or `LDRSBT` instruction.

A Data Abort exception is generated if the processor attempts a data access that the access rights do not permit. For example, a Data Abort exception is generated if the processor is at PL0 and attempts to access a memory region that is marked as only accessible to privileged memory accesses.

A3.6.3 Privilege level access controls for instruction accesses

Memory attributes access permissions assigned at PL1 can define that a memory region is:

- Not accessible for execution.
- Not accessible for execution at PL1 Only implementations that include the Large Physical Address Extension support this attribute.

- Accessible for execution only at PL1.
- Accessible for execution at any level of privilege.

In Non-secure state, in an implementation that includes the Virtualization Extensions, separate memory access permissions can be assigned at PL2 for:

- Accesses made at PL1 and PL0.
- Accesses made at PL2.

To define the instruction access rights to a memory region, the memory attributes describe, separately, for the region:

- Its read access rights. These are equivalent to the read access rights described in *Privilege level access controls for data accesses* on page A3-142.
- Whether software can be executed from the region. This is indicated by whether or not an *Execute-never* (XN) attribute is assigned to the region.
- For an implementation that includes the Large Physical Address Extension, whether software can be executed at PL1 from the region. This is indicated by whether or not a *Privileged execute-never* (PXN) attribute is assigned to the region.

This means there is a linkage between the memory attributes that define the accessibility of a region to data accesses, and those that define whether instructions can be executed from the region. For example, a region that is accessible for execution only at PL1 or higher:

- Has the memory attribute indicating that it is accessible only to read accesses at PL1 or higher.
- Does not have the Execute-never attribute
- If the implementation includes the Large Physical Address Extension, does not have the Privileged execute-never attribute.

Any attempt to execute an instruction from a memory location with an applicable execute-never attribute generates a memory fault.

A3.6.4 Memory region security status

If an implementation includes the Security Extensions, an additional memory attribute determines whether the memory region is Secure or Non-secure. Such an implementation checks this attribute, to ensure that a region of memory that the system designates as Secure is not accessed by memory accesses with the Non-secure memory attribute. For more information, see *Memory region attributes* on page B3-1366.

A3.7 Virtual and physical addressing

ARMv7 provides three alternative architectural profiles, ARMv7-A, ARMv7-R and ARMv7-M. Each of the profiles specifies a different memory system. This manual describes two of these profiles:

ARMv7-A profile

The ARMv7-A memory system incorporates a *Memory Management Unit* (MMU), controlled by CP15 registers. The memory system supports virtual addressing, with the MMU performing virtual to physical address translation, in hardware, as part of program execution.

An ARMv7-A processor that implements the Virtualization Extensions provides two stages of address translation for processes running at the Application level:

- The operating system defines the mappings from virtual addresses to *intermediate physical addresses* (IPAs). When it does this, it believes it is mapping virtual addresses to physical addresses.
- The hypervisor defines the mappings from IPAs to physical addresses. These translations are invisible to the operating system.

For more information see *About address translation* on page B3-1311.

ARMv7-R profile

The ARMv7-R memory system incorporates a *Memory Protection Unit* (MPU), controlled by CP15 registers. The MPU does not support virtual addressing.

At the Application level, the difference between the ARMv7-A and ARMv7-R memory systems is transparent. Regardless of which profile is implemented, an application accesses the memory map described in *Address space* on page A3-106, and the implemented memory system makes the features described in this chapter available to the application.

For a system level description of the ARMv7-A and ARMv7-R memory models see:

- Chapter B2 *Common Memory System Architecture Features*
- Chapter B3 *Virtual Memory System Architecture (VMSA)*
- Chapter B5 *Protected Memory System Architecture (PMSA)*.

Note

This manual does not describe the ARMv7-M profile. For details of this profile see the *ARMv7-M Architecture Reference Manual*.

A3.8 Memory access order

ARMv7 provides a set of three memory types, Normal, Device, and Strongly-ordered, with well-defined memory access properties.

The ARMv7 application level view of the memory attributes is described in:

- *Memory types and attributes and the memory order model* on page A3-125
- *Access rights* on page A3-141.

When considering memory access ordering, an important feature of the ARMv7 memory model is the *Shareable* memory attribute, that indicates whether a region of memory appears coherent for data accesses made by multiple observers.

The key issues with the memory order model depend on the target audience:

- For software programmers, considering the model at the Application level, the key factor is that for accesses to Normal memory barriers are required in some situations where the order of accesses observed by other observers must be controlled.
- For silicon implementers, considering the model at the system level, the Strongly-ordered and Device memory attributes place certain restrictions on the system designer in terms of what can be built and when to indicate completion of an access.

  Note

  Implementations remain free to choose the mechanisms required to implement the functionality of the memory model.

More information about the memory order model is given in the following subsections:

- *Reads and writes*
- *Ordering requirements for memory accesses* on page A3-148
- *Memory barriers* on page A3-150.

Additional attributes and behaviors relate to the memory system architecture. These features are defined in the system level section of this manual:

- Virtual memory systems based on an MMU, described in Chapter B3 *Virtual Memory System Architecture (VMSA)*.
- Protected memory systems based on an MPU, described in Chapter B5 *Protected Memory System Architecture (PMSA)*.
- Caches, described in *Caches and branch predictors* on page B2-1266.

Note

In these system level descriptions, some attributes are described in relation to an MMU. In general, these descriptions can also be applied to an MPU based system.

A3.8.1 Reads and writes

Each memory access is either a read or a write. *Explicit* memory accesses are the memory accesses required by the function of an instruction. The following can cause memory accesses that are not explicit:

- instruction fetches
- cache loads and write-backs
- translation table walks.

Except where otherwise stated, the memory ordering requirements only apply to explicit memory accesses.

Reads

Reads are defined as memory operations that have the semantics of a load.

The memory accesses of the following instructions are reads:

- LDR, LDRB, LDRH, LDRSB, and LDRSH.
- LDRT, LDRBT, LDRHT, LDRSBT, and LDRSHT.
- LDREX, LDREXB, LDREXD, and LDREXH.
- LDM, LDRD, POP, and RFE.
- LDC, LDC2, VLDM, VLDR, VLD1, VLD2, VLD3, VLD4, and VPOP.
- The return of status values by STREX, STREXB, STREXD, and STREXH.
- SWP and SWPB. These instructions are available only in the ARM instruction set.
- TBB and TBH. These instructions are available only in the Thumb instruction set.

Hardware-accelerated opcode execution by the Jazelle extension can cause a number of reads to occur, according to the state of the operand stack and the implementation of the Jazelle hardware acceleration.

Writes

Writes are defined as memory operations that have the semantics of a store.

The memory accesses of the following instructions are Writes:

- STR, STRB, and STRH.
- STRT, STRBT, and STRHT.
- STREX, STREXB, STREXD, and STREXH.
- STM, STRD, PUSH, and SRS.
- STC, STC2, VPUSH, VSTM, VSTR, VST1, VST2, VST3, and VST4.
- SWP and SWPB. These instructions are available only in the ARM instruction set.

Hardware-accelerated opcode execution by the Jazelle extension can cause a number of writes to occur, according to the state of the operand stack and the implementation of the Jazelle hardware acceleration.

Synchronization primitives

Synchronization primitives must ensure correct operation of system semaphores in the memory order model. The synchronization primitive instructions are defined as those instructions that are executed to ensure memory synchronization. They are the following instructions:

- LDREX, STREX, LDREXB, STREXB, LDREXD, STREXD, LDREXH, STREXH.
- SWP, SWPB. From ARMv6, ARM deprecates the use of these instructions.

Observability and completion

An *observer* is an agent in the system that can access memory. For a processor, the following mechanisms must be treated as independent observers:

- the mechanism that performs reads or writes to memory
- a mechanism that causes an instruction cache to be filled from memory or that fetches instructions to be executed directly from memory
- a mechanism that performs translation table walks.

The set of observers that can observe a memory access is defined by the system.

In the definitions in this subsection, *subsequent* means whichever of the following is appropriate to the context:

- after the point in time where the location is observed by that observer
- after the point in time where the location is globally observed.

For all memory:

- a write to a location in memory is said to be *observed* by an observer when:
  - a subsequent read of the location by the same observer will return the value written by the observed write, or written by a write to that location by any observer that is sequenced in the Coherence order of the location after the observed write
  - a subsequent write of the location by the same observer will be sequenced in the Coherence order of the location after the observed write
- a write to a location in memory is said to be *globally observed* for a shareability domain when:
  - a subsequent read of the location by any observer in that shareability domain will return the value written by the globally observed write, or written by a write to that location by any observer that is sequenced in the Coherence order of the location after the globally observed write
  - a subsequent write of the location by any observer in that shareability domain will be sequenced in the Coherence order of the location after the globally observed write
- a read of a location in memory is said to be observed by an observer when a subsequent write to the location by the same observer will have no effect on the value returned by the read
- a read of a location in memory is said to be globally observed for a shareability domain when a subsequent write to the location by any observer in that shareability domain will have no effect on the value returned by the read.

Additionally, for Strongly-ordered memory:

- A read or write of a memory-mapped location in a peripheral that exhibits side-effects is said to be observed, and globally observed, only when the read or write:
  - meets the general conditions listed
  - can begin to affect the state of the memory-mapped peripheral
  - can trigger all associated side-effects, whether they affect other peripheral devices, processors, or memory.

  Note

  This definition is consistent with the memory access having reached the peripheral.

For all memory, the completion rules are defined as:

- A read or write is complete for a shareability domain when all of the following are true:
  - the read or write is globally observed for that shareability domain
  - any translation table walks associated with the read or write are complete for that shareability domain.
- A translation table walk is complete for a shareability domain when the memory accesses associated with the translation table walk are globally observed for that shareability domain, and the TLB is updated.
- A cache, branch predictor, or TLB maintenance operation is complete for a shareability domain when the effects of the operation are globally observed for that shareability domain, and any translation table walks that arise from the operation are complete for that shareability domain.

  The completion of any cache, branch predictor or TLB maintenance operation includes its completion on all processors that are affected by both the operation and the DSB operation that is required to guarantee visibility of the maintenance operation.

Completion of side-effects of accesses to Strongly-ordered and Device memory

The completion of a memory access to Strongly-ordered or Device memory is not guaranteed to be sufficient to determine that the side-effects of the memory access are visible to all observers. The mechanism that ensures the visibility of side-effects of a memory access is IMPLEMENTATION DEFINED.

A3.8.2 Ordering requirements for memory accesses

ARMv7 and ARMv6 define access restrictions in the permitted ordering of memory accesses. These restrictions depend on the memory attributes of the accesses involved.

Two terms used in describing the memory access ordering requirements are:

Address dependency

An address dependency exists when the value returned by a read access is used for the computation of the virtual address of a subsequent read or write access. An address dependency exists even if the value read by the first read access does not change the virtual address of the second read or write access. This might be the case if the value returned is masked off before it is used, or if it has no effect on the predicted address value for the second access.

Control dependency

A control dependency exists when the data value returned by a read access determines the condition flags, and the values of the flags are used in the condition code checking that determines the address of a subsequent read access. This address determination might be through conditional execution, or through the evaluation of a branch.

Figure A3-5 shows the memory ordering between two explicit accesses A1 and A2, where A1 occurs before A2 in program order. In the figure, an access refers to a read or a write access to the specified memory type. For example, *Normal access* refers to a read or write access to Normal memory. The symbols used in the figure are as follows:

< Accesses must arrive at any particular memory-mapped peripheral or block of memory in program order, that is, A1 must arrive before A2. There are no ordering restrictions about when accesses arrive at different peripherals or blocks of memory, provided that accesses follow the general ordering rules given in this section.

\- Accesses can arrive at any memory-mapped peripheral or block of memory in any order, provided that the accesses follow the general ordering rules given in this section.

The size of a memory mapped peripheral, or a block of memory, is IMPLEMENTATION DEFINED, but is not smaller than 1KByte.

Note

This implies that the maximum memory-mapped peripheral size for which the architecture guarantees order for all implementations is 1KB.

A1 \ A2	Normal access	Device access ‡	Strongly-ordered access ‡
Normal access	-	-	-
Device access	-	<	<
Strongly-ordered access	-	<	<

‡ The ordering requirements for Device and Strongly-ordered accesses are identical.

Figure A3-5 Memory ordering restrictions

There are no ordering requirements for implicit accesses to any type of memory.

The following additional restrictions apply to the ordering of all memory accesses:

- For all accesses from a single observer, the requirements of uniprocessor semantics must be maintained, for example:
  - respecting dependencies between instructions in a single processor
  - coherency.

- If there is an address dependency then the two memory accesses are observed in program order by any observer in the common shareability domain of the two accesses.

  This ordering restriction does not apply if there is only a control dependency between the two read accesses.

  If there is both an address dependency and a control dependency between two read accesses the ordering requirements of the address dependency apply.

- If the value returned by a read access is used as data written by a subsequent write access, then the two memory accesses are observed in program order by any observer in the common shareability domain of the two accesses.

- It is impossible for an observer in the shareability domain of a memory location to observe an access by a store instruction that has not been architecturally executed.

- It is impossible for an observer in the shareability domain of a memory location to observe two reads to the same memory location performed by the same observer in an order that would not occur in a sequential execution of a program.

- For an implementation that does not include the Multiprocessing Extensions, it is IMPLEMENTATION DEFINED whether all writes complete in a finite period of time, or whether some writes require the execution of a `DSB` instruction to guarantee their completion.

- For an implementation that includes the Multiprocessing Extensions, all writes complete in a finite period of time.

  Note

  This applies for all writes, including repeated writes to the same location.

Program order for instruction execution

The program order of instruction execution is the order of the instructions in a simple sequential execution of the program.

Explicit memory accesses in an execution can be either:

Strictly Ordered
: Denoted by <. Must occur strictly in order.

Ordered
: Denoted by <=. Can occur either in order or simultaneously.

Load/store multiple instructions, such as `LDM`, `LDRD`, `STM`, and `STRD`, generate multiple word accesses, each of which is a separate access for the purpose of determining ordering.

The rules for determining program order for two accesses A1 and A2 are:

If A1 and A2 are generated by two different instructions:

- A1 < A2 if the instruction that generates A1 occurs before the instruction that generates A2 in program order
- A2 < A1 if the instruction that generates A2 occurs before the instruction that generates A1 in program order.

If A1 and A2 are generated by the same instruction:

- If A1 and A2 are the load and store generated by a `SWP` or `SWPB` instruction:
  - A1 < A2 if A1 is the load and A2 is the store
  - A2 < A1 if A2 is the load and A1 is the store.

- In these descriptions:
  - an *LDM-class* instruction is any form of LDM, LDMDA, LDMDB, or LDMIB, or a POP instruction that operates on more than one register
  - an *LDC-class* instruction is an LDC, VLDM, VLDR, or VPOP instruction
  - an *STM-class* instruction is any form of STM, STMDA, STMDB, or STMIB, or a PUSH instruction that operates on more than one register
  - an *STC-class* instruction is an STC, VSTM, VSTR, or VPUSH instruction.

  If A1 and A2 are two word loads generated by an LDC-class or LDM-class instruction, or two word stores generated by an STC-class or STM-class instruction, excluding LDM-class and STM-class instructions with a register list that includes the PC:
  - A1 <= A2 if the address of A1 is less than the address of A2
  - A2 <= A1 if the address of A2 is less than the address of A1.

  If A1 and A2 are two word loads generated by an LDM-class instruction with a register list that includes the PC or two word stores generated by an STM-class instruction with a register list that includes the PC, the program order of the memory accesses is not defined.
- If A1 and A2 are two word loads generated by an LDRD instruction or two word stores generated by an STRD instruction, the program order of the memory accesses is not defined.
- If A1 and A2 are load or store accesses generated by Advanced SIMD element or structure load/store instructions, the program order of the memory accesses is not defined.
- For any instruction or operation not explicitly mentioned in this section, if the single-copy atomicity rules described in *Single-copy atomicity* on page A3-127 mean the operation becomes a sequence of accesses, then the time-ordering of those accesses is not defined.

A3.8.3 Memory barriers

Memory barrier is the general term applied to an instruction, or sequence of instructions, that forces synchronization events by a processor with respect to retiring load/store instructions. The ARM architecture defines a number of memory barriers that provide a range of functionality, including:

- ordering of load/store instructions
- completion of load/store instructions
- context synchronization.

ARMv7 and ARMv6 require three explicit memory barriers to support the memory order model described in this chapter. In ARMv7 the memory barriers are provided as instructions that are available in the ARM and Thumb instruction sets, and in ARMv6 the memory barriers are performed by CP15 register writes. The three memory barriers are:

- Data Memory Barrier, see *Data Memory Barrier (DMB)* on page A3-151
- Data Synchronization Barrier, see *Data Synchronization Barrier (DSB)* on page A3-152
- Instruction Synchronization Barrier, see *Instruction Synchronization Barrier (ISB)* on page A3-152.

Note

Depending on the required synchronization, a program might use memory barriers on their own, or it might use them in conjunction with cache and memory management maintenance operations that are only available when software execution is at PL1 or higher.

The DMB and DSB memory barriers affect reads and writes to the memory system generated by load/store instructions and data or unified cache maintenance operations being executed by the processor. Instruction fetches or accesses caused by a hardware translation table access are not explicit accesses.

Data Memory Barrier (DMB)

The DMB instruction is a data memory barrier. The processor that executes the DMB instruction is referred to as the executing processor, Pe. The DMB instruction takes the *required shareability domain* and *required access types* as arguments, see *Shareability and access limitations on the data barrier operations* on page A3-152. If the required shareability is *Full system* then the operation applies to all observers within the system.

A DMB creates two groups of memory accesses, Group A and Group B:

Group A Contains:

- All explicit memory accesses of the required access types from observers in the same required shareability domain as Pe that are observed by Pe before the DMB instruction. These accesses include any accesses of the required access types performed by Pe.
- All loads of required access types from an observer Px in the same required shareability domain as Pe that have been observed by any given different observer, Py, in the same required shareability domain as Pe before Py has performed a memory access that is a member of Group A.

Group B Contains:

- All explicit memory accesses of the required access types by Pe that occur in program order after the DMB instruction.
- All explicit memory accesses of the required access types by any given observer Px in the same required shareability domain as Pe that can only occur after a load by Px has returned the result of a store that is a member of Group B.

Any observer with the same required shareability domain as Pe observes all members of Group A before it observes any member of Group B to the extent that those group members are required to be observed, as determined by the shareability and cacheability of the memory locations accessed by the group members.

Where members of Group A and members of Group B access the same memory-mapped peripheral or block of memory, of arbitrary system-defined size, then members of Group A that are accessing Strongly-ordered, Device, or Normal Non-cacheable memory arrive at that peripheral or block of memory before members of Group B that are accessing Strongly-ordered, Device, or Normal Non-cacheable memory.

Note

- Where the members of Group A and Group B that must be ordered are from the same processor, a DMB NSH is sufficient for this guarantee.
- A memory access might be in neither Group A nor Group B. The DMB does not affect the order of observation of such a memory access.
- The second part of the definition of Group A is recursive. Ultimately, membership of Group A derives from the observation by Py of a load before Py performs an access that is a member of Group A as a result of the first part of the definition of Group A.
- The second part of the definition of Group B is recursive. Ultimately, membership of Group B derives from the observation by any observer of an access by Pe that is a member of Group B as a result of the first part of the definition of Group B.

DMB only affects memory accesses and data and unified cache maintenance operations, see *Cache and branch predictor maintenance operations* on page B2-1277. It has no effect on the ordering of any other instructions executing on the processor.

For details of the DMB instruction in the Thumb and ARM instruction sets see *DMB* on page A8-378.

Data Synchronization Barrier (DSB)

The DSB instruction is a special memory barrier, that synchronizes the execution stream with memory accesses. The DSB instruction takes the *required shareability domain* and *required access types* as arguments, see *Shareability and access limitations on the data barrier operations*. If the required shareability is *Full system* then the operation applies to all observers within the system.

A DSB behaves as a DMB with the same arguments, and also has the additional properties defined here.

A DSB completes when:

- all explicit memory accesses that are observed by Pe before the DSB is executed, are of the required access types, and are from observers in the same required shareability domain as Pe, are complete for the set of observers in the required shareability domain
- all cache and branch predictor maintenance operations issued by Pe before the DSB are complete for the required shareability domain.
- if the required accesses types of the DSB is reads and writes, all TLB maintenance operations issued by Pe before the DSB are complete for the required shareability domain.

In addition, no instruction that appears in program order after the DSB instruction can execute until the DSB completes.

For details of the DSB instruction in the Thumb and ARM instruction sets see *DSB* on page A8-380.

Note

Historically, this operation was referred to as *Drain Write Buffer* or *Data Write Barrier* (DWB). From ARMv6, these names and the use of DWB were deprecated in favor of the new *Data Synchronization Barrier* name and DSB abbreviation. DSB better reflects the functionality provided from ARMv6, because DSB is architecturally defined to include all cache, TLB and branch prediction maintenance operations as well as explicit memory operations.

Instruction Synchronization Barrier (ISB)

An ISB instruction flushes the pipeline in the processor, so that all instructions that come after the ISB instruction in program order are fetched from cache or memory only after the ISB instruction has completed. Using an ISB ensures that the effects of context-changing operations executed before the ISB are visible to the instructions fetched after the ISB instruction. Examples of context-changing operations that require the insertion of an ISB instruction to ensure the effects of the operation are visible to instructions fetched after the ISB instruction are:

- completed cache, TLB, and branch predictor maintenance operations
- changes to system control registers.

Any context-changing operations appearing in program order after the ISB instruction only take effect after the ISB has been executed.

For more information about the ISB instruction in the Thumb and ARM instruction sets, see *ISB* on page A8-389.

Shareability and access limitations on the data barrier operations

The DMB and DSB instructions can each take an optional limitation argument that specifies:

- the shareability domain over which the instruction must operate, as one of:
  - full system
  - Outer Shareable
  - Inner Shareable
  - Non-shareable
- the accesses for which the instruction operates, as one of:
  - read and write accesses
  - write accesses only.

By default, each instruction operates for read and write accesses, over the full system, and whether an implementation supports any other options is IMPLEMENTATION DEFINED. See the instruction descriptions for more information about these arguments.

Note

`ISB` also supports an optional limitation argument, but supports only one value for that argument, that corresponds to full system operation.

In an implementation that includes the Virtualization Extensions, and supports shareability limitations on the data barrier operations, the HCR.BSU field can upgrade the required shareability of the operation for an instruction that is executed in a Non-secure PL1 or PL0 mode. Table A3-6 shows the encoding of this field:

Table A3-6 HCR.BSU encoding

HCR.BSU	Minimum shareability of instruction
00	No effect, shareability is as specified by the instruction
01	Inner Shareable
10	Outer Shareable
11	Full system

For an instruction executed in a Non-secure PL1 or PL0 mode, Table A3-7 shows how HCR.BSU upgrades the shareability specified by the argument of the `DMB` or `DSB` instruction:

Table A3-7 Upgrading the shareability of data barrier operations

Shareability from `DMB` or `DSB` argument	HCR.BSU	Resultant shareability
Full system	Any	Full system
Outer Shareable	`00`, `01`, or `10`	Outer Shareable
	`11`, Full system	Full system
Inner Shareable	`00` or `01`	Inner Shareable
	`10`, Outer Shareable	Outer Shareable
	`11`, Full system	Full system
Non-shareable	`00`, No effect	Non-shareable
	`01`, Inner Shareable	Inner Shareable
	`10`, Outer Shareable	Outer Shareable
	`11`, Full system	Full system

Pseudocode details of memory barriers

The following types define the required shareability domains and required access types used as arguments for DMB and DSB instructions:

```
enumeration MBReqDomain {MBReqDomain_FullSystem,
                         MBReqDomain_OuterShareable,
                         MBReqDomain_InnerShareable,
                         MBReqDomain_Nonshareable};

enumeration MBReqTypes {MBReqTypes_All, MBReqTypes_Writes};
```

The following procedures perform the memory barriers:

```
DataMemoryBarrier(MBReqDomain domain, MBReqTypes types)

DataSynchronizationBarrier(MBReqDomain domain, MBReqTypes types)

InstructionSynchronizationBarrier()
```

A3.9 Caches and memory hierarchy

The implementation of a memory system depends heavily on the microarchitecture and therefore the details of the system are IMPLEMENTATION DEFINED. ARMv7 defines the application level interface to the memory system, and supports a hierarchical memory system with multiple levels of cache. This section provides an application level view of this system. It contains the subsections:

- *Introduction to caches*
- *Memory hierarchy*
- *Implication of caches for the application programmer* on page A3-156
- *Preloading caches* on page A3-157.

A3.9.1 Introduction to caches

A cache is a block of high-speed memory that contains a number of entries, each consisting of:

- main memory address information, commonly called a *tag*
- the associated data.

Caches increase the average speed of a memory access. Cache operation takes account of two principles of locality:

Spatial locality

An access to one location is likely to be followed by accesses to adjacent locations. Examples of this principle are:

- sequential instruction execution
- accessing a data structure.

Temporal locality

An access to an area of memory is likely to be repeated in a short time period. An example of this principle is the execution of a software loop.

To minimize the quantity of control information stored, the spatial locality property groups several locations together under the same tag. This logical block is commonly called a cache line. When data is loaded into a cache, access times for subsequent loads and stores are reduced, resulting in overall performance benefits. An access to information already in a cache is called a cache hit, and other accesses are called cache misses.

Normally, caches are self-managing, with the updates occurring automatically. Whenever the processor wants to access a cacheable location, the cache is checked. If the access is a cache hit, the access occurs in the cache, otherwise a location is allocated and the cache line loaded from memory. Different cache topologies and access policies are possible, however, they must comply with the memory coherency model of the underlying architecture.

Caches introduce a number of potential problems, mainly because of:

- memory accesses occurring at times other than when the programmer would otherwise expect them
- there being multiple physical locations where a data item can be held.

A3.9.2 Memory hierarchy

Memory close to a processor has very low latency, but is limited in size and expensive to implement. Further from the processor it is easier to implement larger blocks of memory but these have increased latency. To optimize overall performance, an ARMv7 memory system can include multiple levels of cache in a hierarchical memory system. Figure A3-6 on page A3-156 shows such a system, in an ARMv7-A implementation of a VMSA, supporting virtual addressing.

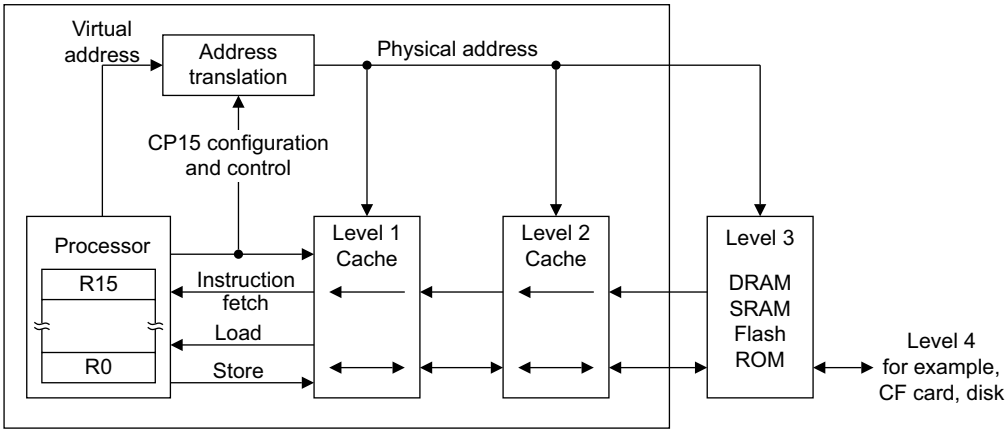


Figure A3-6 Multiple levels of cache in a memory hierarchy

Note

In this manual, in a hierarchical memory system, Level 1 refers to the level closest to the processor, as shown in Figure A3-6.

A3.9.3 Implication of caches for the application programmer

In normal operation, the caches are largely invisible to the application programmer. However they can become visible when there is a breakdown in the coherency of the caches. Such a breakdown can occur:

- when memory locations are updated by other agents in the system
- when memory updates made from the application software must be made visible to other agents in the system.

For example:

- In a system with a DMA controller that reads memory locations that are held in the data cache of a processor, a breakdown of coherency occurs when the processor has written new data in the data cache, but the DMA controller reads the old data held in memory.
- In a Harvard architecture of caches, where there are separate instruction and data caches, a breakdown of coherency occurs when new instruction data has been written into the data cache, but the instruction cache still contains the old instruction data.

Data coherency issues

Software can ensure the data coherency of caches in the following ways:

- By not using the caches in situations where coherency issues can arise. This can be achieved by:
  - using Non-cacheable or, in some cases, Write-Through Cacheable memory
  - not enabling caches in the system.
- By using cache maintenance operations to manage the coherency issues in software, see *About ARMv7 cache and branch predictor maintenance functionality* on page B2-1273. Many of these operations are only available to system software.
- By using hardware coherency mechanisms to ensure the coherency of data accesses to memory for cacheable locations by observers within the different shareability domains, see *Non-shareable Normal memory* on page A3-131 and *Shareable, Inner Shareable, and Outer Shareable Normal memory* on page A3-132.

The performance of these hardware coherency mechanisms is highly implementation-specific. In some implementations the mechanism suppresses the ability to cache shareable locations. In other implementations, cache coherency hardware can hold data in caches while managing coherency between observers within the shareability domains.

Instruction coherency issues

How far ahead of the current point of execution instructions are fetched from is IMPLEMENTATION DEFINED. Such prefetching can be either a fixed or a dynamically varying number of instructions, and can follow any or all possible future execution paths. For all types of memory:

- the processor might have fetched the instructions from memory at any time since the last context synchronization operation on that processor
- any instructions fetched in this way might be executed multiple times, if this is required by the execution of the program, without being refetched from memory

Note

See *Context synchronization operation* for the definition of this term.

In addition, the ARM architecture does not require the hardware to ensure coherency between instruction caches and memory, even for regions of memory with Shareable attributes. This means that for cacheable regions of memory, an instruction cache can hold instructions that were fetched from memory before the context synchronization operation.

If software requires coherency between instruction execution and memory, it must manage this coherency using the ISB and DSB memory barriers and cache maintenance operations, see *Ordering of cache and branch predictor maintenance operations* on page B2-1289. Many of these operations are only available to system software.

A3.9.4 Preloading caches

The ARM architecture provides memory system hints `PLD` (Preload Data), `PLDW` (Preload Data with intent to write), and `PLI` (Preload Instruction) to permit software to communicate the expected use of memory locations to the hardware. The memory system can respond by taking actions that are expected to speed up the memory accesses if and when they do occur. The effect of these memory system hints is IMPLEMENTATION DEFINED. Typically, implementations use this information to bring the data or instruction locations into caches that have faster access times than normal memory.

The Preload instructions are hints, and so implementations can treat them as NOPs without affecting the functional behavior of the device. The instructions do not generate synchronous Data Abort exceptions, but the memory system operations might, under exceptional circumstances, generate asynchronous aborts. For more information, see *Data Abort exception* on page B1-1214.

For more information about the operation of these instructions see *Behavior of Preload Data (PLD, PLDW) and Preload Instruction (PLI) with caches* on page B2-1269.

Hardware implementations can provide other implementation-specific mechanisms to fetch memory locations in the cache. These must comply with the general cache behavior described in *Cache behavior* on page B2-1267.

Chapter A4
The Instruction Sets

This chapter describes the ARM and Thumb instruction sets. It contains the following sections:

- *About the instruction sets* on page A4-160
- *Unified Assembler Language* on page A4-162
- *Branch instructions* on page A4-164
- *Data-processing instructions* on page A4-165
- *Status register access instructions* on page A4-174
- *Load/store instructions* on page A4-175
- *Load/store multiple instructions* on page A4-177
- *Miscellaneous instructions* on page A4-178
- *Exception-generating and exception-handling instructions* on page A4-179
- *Coprocessor instructions* on page A4-180
- *Advanced SIMD and Floating-point load/store instructions* on page A4-181
- *Advanced SIMD and Floating-point register transfer instructions* on page A4-183
- *Advanced SIMD data-processing instructions* on page A4-184
- *Floating-point data-processing instructions* on page A4-191.

A4.1 About the instruction sets

ARMv7 contains two main instruction sets, the ARM and Thumb instruction sets. Much of the functionality available is identical in the two instruction sets. This chapter describes the functionality available in the instruction sets, and the *Unified Assembler Language* (UAL) that can be assembled to either instruction set.

The two instruction sets differ in how instructions are encoded:

- Thumb instructions are either 16-bit or 32-bit, and are aligned on a two-byte boundary. 16-bit and 32-bit instructions can be intermixed freely. Many common operations are most efficiently executed using 16-bit instructions. However:
  - Most 16-bit instructions can only access the first eight of the ARM core registers, R0-R7. These are called the *low registers*. A small number of 16-bit instructions can also access the high registers, R8-R15.
  - Many operations that would require two or more 16-bit instructions can be more efficiently executed with a single 32-bit instruction.
  - All 32-bit instructions can access all of the ARM core registers, R0-R15.
- ARM instructions are always 32-bit, and are aligned on a four-byte boundary.

The ARM and Thumb instruction sets can *interwork* freely, that is, different procedures can be compiled or assembled to different instruction sets, and still be able to call each other efficiently.

ThumbEE is a variant of the Thumb instruction set that is designed as a target for dynamically generated code. However, it cannot interwork freely with the ARM and Thumb instruction sets.

In an implementation that includes a non-trivial Jazelle extension, the processor can execute some Java bytecodes in hardware. For more information see *Jazelle direct bytecode execution support* on page A2-97. The processor executes Java bytecodes when it is in Jazelle state. However, this execution is outside the scope of this manual.

See:

- Chapter A5 *ARM Instruction Set Encoding* for encoding details of the ARM instruction set
- Chapter A6 *Thumb Instruction Set Encoding* for encoding details of the Thumb instruction set
- Chapter A8 *Instruction Details* for detailed descriptions of the instructions
- Chapter A9 *The ThumbEE Instruction Set* for encoding details of the ThumbEE instruction set.

A4.1.1 Changing between Thumb state and ARM state

A processor in ARM state executes ARM instructions, and a processor in Thumb state executes Thumb instructions. A processor in Thumb state can enter ARM state by executing any of the following instructions: `BX`, `BLX`, or an `LDR` or `LDM` that loads the PC.

A processor in ARM state can enter Thumb state by executing any of the same instructions.

In ARMv7, a processor in ARM state can also enter Thumb state by executing an `ADC`, `ADD`, `AND`, `ASR`, `BIC`, `EOR`, `LSL`, `LSR`, `MOV`, `MVN`, `ORR`, `ROR`, `RRX`, `RSB`, `RSC`, `SBC`, or `SUB` instruction that has the PC as destination register and does not set the condition flags.

Note

This permits calls and returns between ARM code written for ARMv4 processors and Thumb code running on ARMv7 processors to function correctly. ARM recommends that new software uses `BX` or `BLX` instructions instead. In particular, ARM recommends that software uses `BX LR` to return from a procedure, not `MOV PC, LR`.

The target instruction set is either encoded directly in the instruction (for the immediate offset version of `BLX`), or is held as bit[0] of an *interworking address*. For details, see the description of the `BXWritePC()` function in *Pseudocode details of operations on ARM core registers* on page A2-47.

Exception entries and returns can also change between ARM and Thumb states. For details see *Exception handling* on page B1-1164.

A4.1.2 Conditional execution

In the ARM and Thumb instruction sets, most instructions can be *conditionally executed*.

In the ARM instruction set, conditional execution means that an instruction only has its normal effect on the programmers' model operation, memory and coprocessors if the N, Z, C and V condition flags in the APSR satisfy a condition specified by the `cond` field in the instruction encoding. If the flags do not satisfy this condition, the instruction acts as a NOP, that is, execution advances to the next instruction as normal, including any relevant checks for exceptions being taken, but has no other effect.

In the Thumb instruction set, different mechanisms control conditional execution:

- For the following Thumb encodings, conditional execution is controlled in a similar way to the ARM instructions:
  - A 16-bit conditional branch instruction encoding, with a branch range of –256 to +254 bytes. Before ARMv6T2, this was the only mechanism for conditional execution in Thumb code.
  - A 32-bit conditional branch instruction encoding, with a branch range of approximately ±1MB.

  For more information about these encodings see *B* on page A8-334.
- The `CBZ` and `CBNZ` instructions, Compare and Branch on Zero and Compare and Branch on Nonzero, are 16-bit conditional instructions with a branch range of +4 to +130 bytes. For details see *CBNZ, CBZ* on page A8-356.
- The 16-bit If-Then instruction makes up to four following instructions conditional, and can make most other Thumb instructions conditional. For details see *IT* on page A8-390. The instructions that are made conditional by an `IT` instruction are called its *IT block*. For any IT block, either:
  - all instructions have the same condition
  - some instructions have one condition, and the other instructions have the inverse condition.

ARM deprecates the conditional execution of any instruction encoding provided by the Advanced SIMD Extension that is not also provided by the Floating-point (VFP) Extension, and strongly recommends that any such instruction that can be conditionally executed is specified with the `<c>` field omitted or set to `AL`. For more information, see *Conditional execution* on page A8-288.

For more information about conditional execution see *Conditional execution* on page A8-288.

A4.1.3 Writing to the PC

Writing to the PC on page A2-46 gives an overview of instructions that write to the PC, including the required behavior of these writes. This information is also given in the appropriate sections of this chapter.

A4.1.4 Permanently UNDEFINED encodings

All versions of the ARM architecture define some encodings as permanently UNDEFINED. That is, permanently UNDEFINED encodings are defined in the ARM instruction set encodings, and in the 16-bit and 32-bit Thumb encodings. From issue C.a of this manual, ARM defines an assembler mnemonic for the unconditional forms of these instructions, see *UDF* on page A8-758.

A4.2 Unified Assembler Language

This document uses the ARM *Unified Assembler Language* (UAL). This assembly language syntax provides a canonical form for all ARM and Thumb instructions.

UAL describes the syntax for the mnemonic and the operands of each instruction. In addition, it assumes that instructions and data items can be given labels. It does not specify the syntax to be used for labels, nor what assembler directives and options are available. See your assembler documentation for these details.

Most earlier ARM assembly language mnemonics are still supported as synonyms, as described in the instruction details.

Note

Most earlier Thumb assembly language mnemonics are *not* supported. For more information, see Appendix H *Legacy Instruction Mnemonics*.

UAL includes *instruction selection* rules that specify which instruction encoding is selected when more than one can provide the required functionality. For example, both 16-bit and 32-bit encodings exist for an `ADD R0, R1, R2` instruction. The most common instruction selection rule is that when both a 16-bit encoding and a 32-bit encoding are available, the 16-bit encoding is selected, to optimize code density.

Syntax options exist to override the normal instruction selection rules and ensure that a particular encoding is selected. These are useful when disassembling code, to ensure that subsequent assembly produces the original code, and in some other situations.

A4.2.1 Conditional instructions

For maximum portability of UAL assembly language between the ARM and Thumb instruction sets, ARM recommends that:

- `IT` instructions are written before conditional instructions in the correct way for the Thumb instruction set.
- When assembling to the ARM instruction set, assemblers check that any `IT` instructions are correct, but do not generate any code for them.

Although other Thumb instructions are unconditional, all instructions that are made conditional by an `IT` instruction must be written with a condition. These conditions must match the conditions imposed by the `IT` instruction. For example, an `ITTEE EQ` instruction imposes the `EQ` condition on the first two following instructions, and the `NE` condition on the next two. Those four instructions must be written with `EQ`, `EQ`, `NE` and `NE` conditions respectively.

Some instructions cannot be made conditional by an `IT` instruction. Some instructions can be conditional if they are the last instruction in the IT block, but not otherwise.

The branch instruction encodings that include a condition code field cannot be made conditional by an `IT` instruction. If the assembler syntax indicates a conditional branch that correctly matches a preceding `IT` instruction, it is assembled using a branch instruction encoding that does not include a condition code field.

A4.2.2 Use of labels in UAL instruction syntax

The UAL syntax for some instructions includes the label of an instruction or a literal data item that is at a fixed offset from the instruction being specified. The assembler must:

1. Calculate the `PC` or `Align(PC, 4)` value of the instruction. The `PC` value of an instruction is its address plus 4 for a Thumb instruction, or plus 8 for an ARM instruction. The `Align(PC, 4)` value of an instruction is its `PC` value ANDed with `0xFFFFFFFC` to force it to be word-aligned. There is no difference between the `PC` and `Align(PC, 4)` values for an ARM instruction, but there can be for a Thumb instruction.
2. Calculate the offset from the `PC` or `Align(PC, 4)` value of the instruction to the address of the labelled instruction or literal data item.
3. Assemble a *PC-relative* encoding of the instruction, that is, one that reads its `PC` or `Align(PC, 4)` value and adds the calculated offset to form the required address.

Note

For instructions that can encode a subtraction operation, if the instruction cannot encode the calculated offset but can encode minus the calculated offset, the instruction encoding specifies a subtraction of minus the calculated offset.

The syntax of the following instructions includes a label:

- `B`, `BL`, and `BLX` (immediate). The assembler syntax for these instructions always specifies the label of the instruction that they branch to. Their encodings specify a sign-extended immediate offset that is added to the `PC` value of the instruction to form the target address of the branch.
- `CBNZ` and `CBZ`. The assembler syntax for these instructions always specifies the label of the instruction that they branch to. Their encodings specify a zero-extended immediate offset that is added to the `PC` value of the instruction to form the target address of the branch. They do not support backward branches.
- `LDC`, `LDC2`, `LDR`, `LDRB`, `LDRD`, `LDRH`, `LDRSB`, `LDRSH`, `PLD`, `PLDW`, `PLI`, and `VLDR`. The normal assembler syntax of these load instructions can specify the label of a literal data item that is to be loaded. The encodings of these instructions specify a zero-extended immediate offset that is either added to or subtracted from the `Align(PC, 4)` value of the instruction to form the address of the data item. A few such encodings perform a fixed addition or a fixed subtraction and must only be used when that operation is required, but most contain a bit that specifies whether the offset is to be added or subtracted.

  When the assembler calculates an offset of 0 for the normal syntax of these instructions, it must assemble an encoding that adds 0 to the `Align(PC, 4)` value of the instruction. Encodings that subtract 0 from the `Align(PC, 4)` value cannot be specified by the normal syntax.

  There is an alternative syntax for these instructions that specifies the addition or subtraction and the immediate offset explicitly. In this syntax, the label is replaced by `[PC, #+/-<imm>]`, where:

  `+/-` Is `+` or omitted to specify that the immediate offset is to be added to the `Align(PC, 4)` value, or `-` if it is to be subtracted.

  `<imm>` Is the immediate offset.

  This alternative syntax makes it possible to assemble the encodings that subtract 0 from the `Align(PC, 4)` value, and to disassemble them to a syntax that can be re-assembled correctly.
- `ADR`. The normal assembler syntax for this instruction can specify the label of an instruction or literal data item whose address is to be calculated. Its encoding specifies a zero-extended immediate offset that is either added to or subtracted from the `Align(PC, 4)` value of the instruction to form the address of the data item, and some opcode bits that determine whether it is an addition or subtraction.

  When the assembler calculates an offset of 0 for the normal syntax of this instruction, it must assemble the encoding that adds 0 to the `Align(PC, 4)` value of the instruction. The encoding that subtracts 0 from the `Align(PC, 4)` value cannot be specified by the normal syntax.

  There is an alternative syntax for this instruction that specifies the addition or subtraction and the immediate value explicitly, by writing them as additions `ADD <Rd>, PC, #<imm>` or subtractions `SUB <Rd>, PC, #<imm>`. This alternative syntax makes it possible to assemble the encoding that subtracts 0 from the `Align(PC, 4)` value, and to disassemble it to a syntax that can be re-assembled correctly.

Note

ARM recommends that where possible, software avoids using:

- The alternative syntax for the `ADR`, `LDC`, `LDC2`, `LDR`, `LDRB`, `LDRD`, `LDRH`, `LDRSB`, `LDRSH`, `PLD`, `PLI`, `PLDW`, and `VLDR` instructions.
- The encodings of these instructions that subtract 0 from the `Align(PC, 4)` value.

A4.3 Branch instructions

Table A4-1 summarizes the branch instructions in the ARM and Thumb instruction sets. In addition to providing for changes in the flow of execution, some branch instructions can change instruction set.

Table A4-1 Branch instructions

Instruction	See	Range, Thumb	Range, ARM
Branch to target address	*B* on page A8-334	±16MB	±32MB
Compare and Branch on Nonzero, Compare and Branch on Zero	*CBNZ, CBZ* on page A8-356	0-126 bytes	a
Call a subroutine Call a subroutine, change instruction set[b]	*BL, BLX (immediate)* on page A8-348	±16MB ±16MB	±32MB ±32MB
Call a subroutine, optionally change instruction set	*BLX (register)* on page A8-350	Any	Any
Branch to target address, change instruction set	*BX* on page A8-352	Any	Any
Change to Jazelle state	*BXJ* on page A8-354	-	-
Table Branch (byte offsets) Table Branch (halfword offsets)	*TBB, TBH* on page A8-736	0-510 bytes 0-131070 bytes	a

a. These instructions do not exist in the ARM instruction set.

b. The range is determined by the instruction set of the `BLX` instruction, not of the instruction it branches to.

Branches to loaded and calculated addresses can be performed by `LDR`, `LDM` and data-processing instructions. For details see *Load/store instructions* on page A4-175, *Load/store multiple instructions* on page A4-177, *Standard data-processing instructions* on page A4-165, and *Shift instructions* on page A4-167.

In addition to the branch instructions shown in Table A4-1:

- In the ARM instruction set, a data-processing instruction that targets the PC behaves as a branch instruction. For more information, see *Data-processing instructions* on page A4-165.
- In the ARM and Thumb instruction sets, a load instruction that targets the PC behaves as a branch instruction. For more information, see *Load/store instructions* on page A4-175.

A4.4 Data-processing instructions

Core data-processing instructions belong to one of the following groups:

- *Standard data-processing instructions*.

  These instructions perform basic data-processing operations, and share a common format with some variations.
- *Shift instructions* on page A4-167.
- *Multiply instructions* on page A4-167.
- *Saturating instructions* on page A4-169.
- *Saturating addition and subtraction instructions* on page A4-169.
- *Packing and unpacking instructions* on page A4-170.
- *Parallel addition and subtraction instructions* on page A4-171.
- *Divide instructions* on page A4-172.
- *Miscellaneous data-processing instructions* on page A4-173.

For extension data-processing instructions, see *Advanced SIMD data-processing instructions* on page A4-184 and *Floating-point data-processing instructions* on page A4-191.

A4.4.1 Standard data-processing instructions

These instructions generally have a destination register Rd, a first operand register Rn, and a second operand. The second operand can be another register Rm, or an immediate constant.

If the second operand is an immediate constant, it can be:

- Encoded directly in the instruction.
- A *modified immediate constant* that uses 12 bits of the instruction to encode a range of constants. Thumb and ARM instructions have slightly different ranges of modified immediate constants. For more information, see *Modified immediate constants in Thumb instructions* on page A6-232 and *Modified immediate constants in ARM instructions* on page A5-200.

If the second operand is another register, it can optionally be shifted in any of the following ways:

`LSL`	Logical Shift Left by 1-31 bits.
`LSR`	Logical Shift Right by 1-32 bits.
`ASR`	Arithmetic Shift Right by 1-32 bits.
`ROR`	Rotate Right by 1-31 bits.
`RRX`	Rotate Right with Extend. For details see *Shift and rotate operations* on page A2-41.

In Thumb code, the amount to shift by is always a constant encoded in the instruction. In ARM code, the amount to shift by is either a constant encoded in the instruction, or the value of a register, Rs.

For instructions other than `CMN`, `CMP`, `TEQ`, and `TST`, the result of the data-processing operation is placed in the destination register. In the ARM instruction set, the destination register can be the PC, causing the result to be treated as a branch address. In the Thumb instruction set, this is only permitted for some 16-bit forms of the `ADD` and `MOV` instructions.

These instructions can optionally set the condition flags, according to the result of the operation. If they do not set the flags, existing flag settings from a previous instruction are preserved.

Table A4-2 on page A4-166 summarizes the main data-processing instructions in the Thumb and ARM instruction sets. Generally, each of these instructions is described in three sections in Chapter A8 *Instruction Details*, one section for each of the following:

- `INSTRUCTION` (immediate) where the second operand is a modified immediate constant.
- `INSTRUCTION` (register) where the second operand is a register, or a register shifted by a constant.
- `INSTRUCTION` (register-shifted register) where the second operand is a register shifted by a value obtained from another register. These are only available in the ARM instruction set.

Table A4-2 Standard data-processing instructions

Instruction	Mnemonic	Notes
Add with Carry	ADC	-
Add	ADD	Thumb instruction set permits use of a modified immediate constant or a zero-extended 12-bit immediate constant.
Form PC-relative Address	ADR	First operand is the PC. Second operand is an immediate constant. Thumb instruction set uses a zero-extended 12-bit immediate constant. Operation is an addition or a subtraction.
Bitwise AND	AND	-
Bitwise Bit Clear	BIC	-
Compare Negative	CMN	Sets flags. Like ADD but with no destination register.
Compare	CMP	Sets flags. Like SUB but with no destination register.
Bitwise Exclusive OR	EOR	-
Copy operand to destination	MOV	Has only one operand, with the same options as the second operand in most of these instructions. If the operand is a shifted register, the instruction is an LSL, LSR, ASR, or ROR instruction instead. For details see *Shift instructions* on page A4-167. The ARM and Thumb instruction sets permit use of a modified immediate constant or a zero-extended 16-bit immediate constant.
Bitwise NOT	MVN	Has only one operand, with the same options as the second operand in most of these instructions.
Bitwise OR NOT	ORN	Not available in the ARM instruction set.
Bitwise OR	ORR	-
Reverse Subtract	RSB	Subtracts first operand from second operand. This permits subtraction from constants and shifted registers.
Reverse Subtract with Carry	RSC	Not available in the Thumb instruction set.
Subtract with Carry	SBC	-
Subtract	SUB	Thumb instruction set permits use of a modified immediate constant or a zero-extended 12-bit immediate constant.
Test Equivalence	TEQ	Sets flags. Like EOR but with no destination register.
Test	TST	Sets flags. Like AND but with no destination register.

A4.4.2 Shift instructions

Table A4-3 lists the shift instructions in the ARM and Thumb instruction sets.

Table A4-3 Shift instructions

Instruction	See
Arithmetic Shift Right	*ASR (immediate)* on page A8-330
Arithmetic Shift Right	*ASR (register)* on page A8-332
Logical Shift Left	*LSL (immediate)* on page A8-468
Logical Shift Left	*LSL (register)* on page A8-470
Logical Shift Right	*LSR (immediate)* on page A8-472
Logical Shift Right	*LSR (register)* on page A8-474
Rotate Right	*ROR (immediate)* on page A8-568
Rotate Right	*ROR (register)* on page A8-570
Rotate Right with Extend	*RRX* on page A8-572

In the ARM instruction set only, the destination register of these instructions can be the PC, causing the result to be treated as an address to branch to.

A4.4.3 Multiply instructions

These instructions can operate on signed or unsigned quantities. In some types of operation, the results are same whether the operands are signed or unsigned.

- Table A4-4 summarizes the multiply instructions where there is no distinction between signed and unsigned quantities.

  The least significant 32 bits of the result are used. More significant bits are discarded.

- Table A4-5 on page A4-168 summarizes the signed multiply instructions.

- Table A4-6 on page A4-168 summarizes the unsigned multiply instructions.

Table A4-4 General multiply instructions

Instruction	See	Operation (number of bits)
Multiply Accumulate	*MLA* on page A8-480	32 = 32 + 32 × 32
Multiply and Subtract	*MLS* on page A8-482	32 = 32 – 32 × 32
Multiply	*MUL* on page A8-502	32 = 32 × 32

Table A4-5 Signed multiply instructions

Instruction	See	Operation (number of bits)
Signed Multiply Accumulate (halfwords)	*SMLABB, SMLABT, SMLATB, SMLATT* on page A8-620	32 = 32 + 16 × 16
Signed Multiply Accumulate Dual	*SMLAD* on page A8-622	32 = 32 + 16 × 16 + 16 × 16
Signed Multiply Accumulate Long	*SMLAL* on page A8-624	64 = 64 + 32 × 32
Signed Multiply Accumulate Long (halfwords)	*SMLALBB, SMLALBT, SMLALTB, SMLALTT* on page A8-626	64 = 64 + 16 × 16
Signed Multiply Accumulate Long Dual	*SMLALD* on page A8-628	64 = 64 + 16 × 16 + 16 × 16
Signed Multiply Accumulate (word by halfword)	*SMLAWB, SMLAWT* on page A8-630	32 = 32 + 32 × 16 [a]
Signed Multiply Subtract Dual	*SMLSD* on page A8-632	32 = 32 + 16 × 16 – 16 × 16
Signed Multiply Subtract Long Dual	*SMLSLD* on page A8-634	64 = 64 + 16 × 16 – 16 × 16
Signed Most Significant Word Multiply Accumulate	*SMMLA* on page A8-636	32 = 32 + 32 × 32 [b]
Signed Most Significant Word Multiply Subtract	*SMMLS* on page A8-638	32 = 32 – 32 × 32 [b]
Signed Most Significant Word Multiply	*SMMUL* on page A8-640	32 = 32 × 32 [b]
Signed Dual Multiply Add	*SMUAD* on page A8-642	32 = 16 × 16 + 16 × 16
Signed Multiply (halfwords)	*SMULBB, SMULBT, SMULTB, SMULTT* on page A8-644	32 = 16 × 16
Signed Multiply Long	*SMULL* on page A8-646	64 = 32 × 32
Signed Multiply (word by halfword)	*SMULWB, SMULWT* on page A8-648	32 = 32 × 16 [a]
Signed Dual Multiply Subtract	*SMUSD* on page A8-650	32 = 16 × 16 – 16 × 16

a. The most significant 32 bits of the 48-bit product are used. Less significant bits are discarded.
b. The most significant 32 bits of the 64-bit product are used. Less significant bits are discarded.

Table A4-6 Unsigned multiply instructions

Instruction	See	Operation (number of bits)
Unsigned Multiply Accumulate Accumulate Long	*UMAAL* on page A8-774	64 = 32 + 32 + 32 × 32
Unsigned Multiply Accumulate Long	*UMLAL* on page A8-776	64 = 64 + 32 × 32
Unsigned Multiply Long	*UMULL* on page A8-778	64 = 32 × 32

A4.4.4 Saturating instructions

Table A4-7 lists the saturating instructions in the ARM and Thumb instruction sets. For more information, see *Pseudocode details of saturation* on page A2-44.

Table A4-7 Saturating instructions

Instruction	See	Operation
Signed Saturate	*SSAT* on page A8-652	Saturates optionally shifted 32-bit value to selected range
Signed Saturate 16	*SSAT16* on page A8-654	Saturates two 16-bit values to selected range
Unsigned Saturate	*USAT* on page A8-796	Saturates optionally shifted 32-bit value to selected range
Unsigned Saturate 16	*USAT16* on page A8-798	Saturates two 16-bit values to selected range

A4.4.5 Saturating addition and subtraction instructions

Table A4-8 lists the saturating addition and subtraction instructions in the ARM and Thumb instruction sets. For more information, see *Pseudocode details of saturation* on page A2-44.

Table A4-8 Saturating addition and subtraction instructions

Instruction	See	Operation
Saturating Add	*QADD* on page A8-540	Add, saturating result to the 32-bit signed integer range
Saturating Subtract	*QSUB* on page A8-554	Subtract, saturating result to the 32-bit signed integer range
Saturating Double and Add	*QDADD* on page A8-548	Doubles one value and adds a second value, saturating the doubling and the addition to the 32-bit signed integer range
Saturating Double and Subtract	*QDSUB* on page A8-550	Doubles one value and subtracts the result from a second value, saturating the doubling and the subtraction to the 32-bit signed integer range

A4.4.6 Packing and unpacking instructions

Table A4-9 lists the packing and unpacking instructions in the ARM and Thumb instruction sets. These are all available from ARMv6T2 in the Thumb instruction set, and from ARMv6 onwards in the ARM instruction set.

Table A4-9 Packing and unpacking instructions

Instruction	See	Operation
Pack Halfword	*PKH* on page A8-522	Combine halfwords
Signed Extend and Add Byte	*SXTAB* on page A8-724	Extend 8 bits to 32 and add
Signed Extend and Add Byte 16	*SXTAB16* on page A8-726	Dual extend 8 bits to 16 and add
Signed Extend and Add Halfword	*SXTAH* on page A8-728	Extend 16 bits to 32 and add
Signed Extend Byte	*SXTB* on page A8-730	Extend 8 bits to 32
Signed Extend Byte 16	*SXTB16* on page A8-732	Dual extend 8 bits to 16
Signed Extend Halfword	*SXTH* on page A8-734	Extend 16 bits to 32
Unsigned Extend and Add Byte	*UXTAB* on page A8-806	Extend 8 bits to 32 and add
Unsigned Extend and Add Byte 16	*UXTAB16* on page A8-808	Dual extend 8 bits to 16 and add
Unsigned Extend and Add Halfword	*UXTAH* on page A8-810	Extend 16 bits to 32 and add
Unsigned Extend Byte	*UXTB* on page A8-812	Extend 8 bits to 32
Unsigned Extend Byte 16	*UXTB16* on page A8-814	Dual extend 8 bits to 16
Unsigned Extend Halfword	*UXTH* on page A8-816	Extend 16 bits to 32

A4.4.7 Parallel addition and subtraction instructions

These instructions perform additions and subtractions on the values of two registers and write the result to a destination register, treating the register values as sets of two halfwords or four bytes. That is, they perform SIMD additions or subtractions on the registers. They are available in ARMv6 and above.

These instructions consist of a prefix followed by a main instruction mnemonic. The prefixes are as follows:

`S` Signed arithmetic modulo 2^8 or 2^{16}.

`Q` Signed saturating arithmetic.

`SH` Signed arithmetic, halving the results.

`U` Unsigned arithmetic modulo 2^8 or 2^{16}.

`UQ` Unsigned saturating arithmetic.

`UH` Unsigned arithmetic, halving the results.

The main instruction mnemonics are as follows:

`ADD16` Adds the top halfwords of two operands to form the top halfword of the result, and the bottom halfwords of the same two operands to form the bottom halfword of the result.

`ASX` Exchanges halfwords of the second operand, and then adds top halfwords and subtracts bottom halfwords.

`SAX` Exchanges halfwords of the second operand, and then subtracts top halfwords and adds bottom halfwords.

`SUB16` Subtracts each halfword of the second operand from the corresponding halfword of the first operand to form the corresponding halfword of the result.

`ADD8` Adds each byte of the second operand to the corresponding byte of the first operand to form the corresponding byte of the result.

`SUB8` Subtracts each byte of the second operand from the corresponding byte of the first operand to form the corresponding byte of the result.

The instruction set permits all 36 combinations of prefix and main instruction operand, as Table A4-10 shows.

See also *Advanced SIMD parallel addition and subtraction* on page A4-185.

Table A4-10 Parallel addition and subtraction instructions

Main instruction	Signed	Saturating	Signed halving	Unsigned	Unsigned saturating	Unsigned halving
`ADD16`, add, two halfwords	`SADD16`	`QADD16`	`SHADD16`	`UADD16`	`UQADD16`	`UHADD16`
`ASX`, add and subtract with exchange	`SASX`	`QASX`	`SHASX`	`UASX`	`UQASX`	`UHASX`
`SAX`, subtract and add with exchange	`SSAX`	`QSAX`	`SHSAX`	`USAX`	`UQSAX`	`UHSAX`
`SUB16`, subtract, two halfwords	`SSUB16`	`QSUB16`	`SHSUB16`	`USUB16`	`UQSUB16`	`UHSUB16`
`ADD8`, add, four words	`SADD8`	`QADD8`	`SHADD8`	`UADD8`	`UQADD8`	`UHADD8`
`SUB8`, subtract, four words	`SSUB8`	`QSUB8`	`SHSUB8`	`USUB8`	`UQSUB8`	`UHSUB8`

A4.4.8 Divide instructions

The ARMv7-R profile introduces support for signed and unsigned integer divide instructions, implemented in hardware, in the Thumb instruction set. For more information see *ARMv7 implementation requirements and options for the divide instructions*.

For descriptions of the instructions see:

- *SDIV* on page A8-600
- *UDIV* on page A8-760.

Note

- The Virtualization Extensions introduce the requirement for an ARMv7-A implementation to include `SDIV` and `UDIV`.
- The ARMv7-M profile also includes the `SDIV` and `UDIV` instructions.

In the ARMv7-R profile, the SCTLR.DZ bit enables divide by zero fault detection:

SCTLR.DZ == 0 Divide-by-zero returns a zero result.

SCTLR.DZ == 1 `SDIV` and `UDIV` generate an Undefined Instruction exception on a divide-by-zero.

The SCTLR.DZ bit is cleared to zero on reset.

In an ARMv7-A profile implementation that supports the `SDIV` and `UDIV` instructions, divide-by-zero always returns a zero result.

ARMv7 implementation requirements and options for the divide instructions

Any implementation of the ARMv7-R profile must include the `SDIV` and `UDIV` instructions in the Thumb instruction set.

Any implementation of the Virtualization Extensions must include the `SDIV` and `UDIV` instructions in the Thumb and ARM instruction sets.

In the ARMv7-R profile, the implementation of `SDIV` and `UDIV` in the ARM instruction set is OPTIONAL.

In an ARMv7-A implementation that does not include the Virtualization Extensions, the implementation of `SDIV` and `UDIV` in both instruction sets is OPTIONAL, but the architecture permits an ARMv7-A implementation to not implement `SDIV` and `UDIV`.

Note

Previous issues of this document have stated that a VMSAv7 implementation might implement `SDIV` and `UDIV` in the Thumb instruction set but not in the ARM instruction set. ARM strongly recommends against this implementation option.

The ID_ISAR0.Divide_instrs field indicates the level of support for these instructions, see *ID_ISAR0, Instruction Set Attribute Register 0, VMSA* on page B4-1607 or *ID_ISAR0, Instruction Set Attribute Register 0, PMSA* on page B6-1854:

- a field value of `0b0001` indicates they are implemented in the Thumb instruction set
- a field value of `0b0010` indicates they are implemented in both the Thumb and ARM instruction sets.

A4.4.9 Miscellaneous data-processing instructions

Table A4-11 lists the miscellaneous data-processing instructions in the ARM and Thumb instruction sets. Immediate values in these instructions are simple binary numbers.

Table A4-11 Miscellaneous data-processing instructions

Instruction	See	Notes
Bit Field Clear	*BFC* on page A8-336	-
Bit Field Insert	*BFI* on page A8-338	-
Count Leading Zeros	*CLZ* on page A8-362	-
Move Top	*MOVT* on page A8-491	Moves 16-bit immediate value to top halfword. Bottom halfword unchanged.
Reverse Bits	*RBIT* on page A8-560	-
Byte-Reverse Word	*REV* on page A8-562	-
Byte-Reverse Packed Halfword	*REV16* on page A8-564	-
Byte-Reverse Signed Halfword	*REVSH* on page A8-566	-
Signed Bit Field Extract	*SBFX* on page A8-598	-
Select Bytes using GE flags	*SEL* on page A8-602	-
Unsigned Bit Field Extract	*UBFX* on page A8-756	-
Unsigned Sum of Absolute Differences	*USAD8* on page A8-792	-
Unsigned Sum of Absolute Differences and Accumulate	*USADA8* on page A8-794	-

A4.5 Status register access instructions

The MRS and MSR instructions move the contents of the *Application Program Status Register* (APSR) to or from an ARM core register, see:

- *MRS* on page A8-496
- *MSR (immediate)* on page A8-498
- *MSR (register)* on page A8-500.

The Application Program Status Register (APSR) on page A2-49 described the APSR.

The condition flags in the APSR are normally set by executing data-processing instructions, and normally control the execution of conditional instructions. However, software can set the condition flags explicitly using the MSR instruction, and can read the current state of the condition flags explicitly using the MRS instruction.

At system level, software can also:

- use these instructions to access the SPSR of the current mode
- use the CPS instruction to change the CPSR.M field and the CPSR.{A, I, F} interrupt mask bits.

For details of the system level use of status register access instructions CPS, MRS, and MSR, see:

- *CPS (Thumb)* on page B9-1976
- *CPS (ARM)* on page B9-1978
- *MRS* on page B9-1988
- *MSR (immediate)* on page B9-1994
- *MSR (register)* on page B9-1996.

A4.5.1 Banked register access instructions

In a processor that implements the Virtualization Extensions, in all modes except User mode, the MRS (Banked register) and MSR (Banked register) instructions move the contents of a Banked ARM core register, the SPSR, or the ELR_hyp, to or from an ARM core register. For instruction descriptions see:

- *MRS (Banked register)* on page B9-1990
- *MSR (Banked register)* on page B9-1992.

Note

These are system level instructions.

A4.6 Load/store instructions

Table A4-12 summarizes the ARM core register load/store instructions in the ARM and Thumb instruction sets. See also:

- *Load/store multiple instructions* on page A4-177
- *Advanced SIMD and Floating-point load/store instructions* on page A4-181.

Load/store instructions have several options for addressing memory. For more information, see *Addressing modes* on page A4-176.

Table A4-12 Load/store instructions

Data type	Load	Store	Load unprivileged	Store unprivileged	Load-Exclusive	Store-Exclusive
32-bit word	LDR	STR	LDRT	STRT	LDREX	STREX
16-bit halfword	-	STRH	-	STRHT	-	STREXH
16-bit unsigned halfword	LDRH	-	LDRHT	-	LDREXH	-
16-bit signed halfword	LDRSH	-	LDRSHT	-	-	-
8-bit byte	-	STRB	-	STRBT	-	STREXB
8-bit unsigned byte	LDRB	-	LDRBT	-	LDREXB	-
8-bit signed byte	LDRSB	-	LDRSBT	-	-	-
Two 32-bit words	LDRD	STRD	-	-	-	-
64-bit doubleword	-	-	-	-	LDREXD	STREXD

A4.6.1 Loads to the PC

The LDR instruction can load a value into the PC. The value loaded is treated as an interworking address, as described by the LoadWritePC() pseudocode function in *Pseudocode details of operations on ARM core registers* on page A2-47.

A4.6.2 Halfword and byte loads and stores

Halfword and byte stores store the least significant halfword or byte from the register, to 16 or 8 bits of memory respectively. There is no distinction between signed and unsigned stores.

Halfword and byte loads load 16 or 8 bits from memory into the least significant halfword or byte of a register. Unsigned loads zero-extend the loaded value to 32 bits, and signed loads sign-extend the value to 32 bits.

A4.6.3 Load unprivileged and Store unprivileged

When executing at PL0, a Load unprivileged or Store unprivileged instruction operates in exactly the same way as the corresponding ordinary load or store instruction. For example, an LDRT instruction executes in exactly the same way as the equivalent LDR instruction. When executed at PL1, Load unprivileged and Store unprivileged instructions behave as they would if they were executed at PL0. For example, an LDRT instruction executes in exactly the way that the equivalent LDR instruction would execute at PL0. In particular, the instructions make unprivileged memory accesses.

The Load unprivileged and Store unprivileged instructions are UNPREDICTABLE if executed at PL2.

For more information, see *Privilege level access controls for data accesses* on page A3-142.

A4.6.4 Exclusive loads and stores

Exclusive loads and stores provide shared memory synchronization. For more information, see *Synchronization and semaphores* on page A3-114.

A4.6.5 Addressing modes

The address for a load or store is formed from two parts: a value from a base register, and an offset.

The base register can be any one of the ARM core registers R0-R12, SP, or LR.

For loads, the base register can be the PC. This permits PC-relative addressing for position-independent code. Instructions marked (literal) in their title in Chapter A8 *Instruction Details* are PC-relative loads.

The offset takes one of three formats:

Immediate The offset is an unsigned number that can be added to or subtracted from the base register value. Immediate offset addressing is useful for accessing data elements that are a fixed distance from the start of the data object, such as structure fields, stack offsets and input/output registers.

Register The offset is a value from an ARM core register. This register cannot be the PC. The value can be added to, or subtracted from, the base register value. Register offsets are useful for accessing arrays or blocks of data.

Scaled register The offset is an ARM core register, other than the PC, shifted by an immediate value, then added to or subtracted from the base register. This means an array index can be scaled by the size of each array element.

The offset and base register can be used in three different ways to form the memory address. The addressing modes are described as follows:

Offset The offset is added to or subtracted from the base register to form the memory address.

Pre-indexed The offset is added to or subtracted from the base register to form the memory address. The base register is then updated with this new address, to permit automatic indexing through an array or memory block.

Post-indexed The value of the base register alone is used as the memory address. The offset is then added to or subtracted from the base register. The result is stored back in the base register, to permit automatic indexing through an array or memory block.

Note

Not every variant is available for every instruction, and the range of permitted immediate values and the options for scaled registers vary from instruction to instruction. See Chapter A8 *Instruction Details* for full details for each instruction.

A4.7 Load/store multiple instructions

Load Multiple instructions load a subset, or possibly all, of the ARM core registers from memory.

Store Multiple instructions store a subset, or possibly all, of the ARM core registers to memory.

The memory locations are consecutive word-aligned words. The addresses used are obtained from a base register, and can be either above or below the value in the base register. The base register can optionally be updated by the total size of the data transferred.

Table A4-13 summarizes the load/store multiple instructions in the ARM and Thumb instruction sets.

Table A4-13 Load/store multiple instructions

Instruction	See
Load Multiple, Increment After or Full Descending	*LDM/LDMIA/LDMFD (Thumb)* on page A8-396
Load Multiple, Decrement After or Full Ascending [a]	*LDMDA/LDMFA* on page A8-400
Load Multiple, Decrement Before or Empty Ascending	*LDMDB/LDMEA* on page A8-402
Load Multiple, Increment Before or Empty Descending [a]	*LDMIB/LDMED* on page A8-404
Pop multiple registers off the stack [b]	*POP (Thumb)* on page A8-534
Push multiple registers onto the stack [c]	*PUSH* on page A8-538
Store Multiple, Increment After or Empty Ascending	*STM (STMIA, STMEA)* on page A8-664
Store Multiple, Decrement After or Empty Descending [a]	*STMDA (STMED)* on page A8-666
Store Multiple, Decrement Before or Full Descending	*STMDB (STMFD)* on page A8-668
Store Multiple, Increment Before or Full Ascending [a]	*STMIB (STMFA)* on page A8-670

a. Not available in the Thumb instruction set.
b. This instruction is equivalent to an `LDM` instruction with the SP as base register, and base register updating.
c. This instruction is equivalent to an `STMDB` instruction with the SP as base register, and base register updating.

When executing at PL1, variants of the `LDM` and `STM` instructions load and store User mode registers. Another system level variant of the `LDM` instruction performs an exception return. For details of these variants, see Chapter B9 *System Instructions*.

A4.7.1 Loads to the PC

The `LDM`, `LDMDA`, `LDMDB`, `LDMIB`, and `POP` instructions can load a value into the PC. The value loaded is treated as an interworking address, as described by the `LoadWritePC()` pseudocode function in *Pseudocode details of operations on ARM core registers* on page A2-47.

A4.8 Miscellaneous instructions

Table A4-14 summarizes the miscellaneous instructions in the ARM and Thumb instruction sets.

Table A4-14 Miscellaneous instructions

Instruction	See
Clear-Exclusive	*CLREX* on page A8-360
Debug Hint	*DBG* on page A8-377
Data Memory Barrier	*DMB* on page A8-378
Data Synchronization Barrier	*DSB* on page A8-380
Instruction Synchronization Barrier	*ISB* on page A8-389
If-Then	*IT* on page A8-390
No Operation	*NOP* on page A8-510
Preload Data	*PLD, PLDW (immediate)* on page A8-524 *PLD (literal)* on page A8-526 *PLD, PLDW (register)* on page A8-528
Preload Instruction	*PLI (immediate, literal)* on page A8-530 *PLI (register)* on page A8-532
Set Endianness	*SETEND* on page A8-604
Send Event	*SEV* on page A8-606
Swap, Swap Byte. Deprecated. [a]	*SWP, SWPB* on page A8-722
Wait For Event	*WFE* on page A8-1104
Wait For Interrupt	*WFI* on page A8-1106
Yield	*YIELD* on page A8-1108

a. Use Load/Store-Exclusive instructions instead, see *Load/store instructions* on page A4-175.

A4.8.1 The Yield instruction

In a *Symmetric Multi-Threading* (SMT) design, a thread can use the `YIELD` instruction to give a hint to the processor that it is running on. The `YIELD` hint indicates that whatever the thread is currently doing is of low importance, and so could yield. For example, the thread might be sitting in a spin-lock. A similar use might be in modifying the arbitration priority of the snoop bus in a multiprocessor (MP) system. Defining such an instruction permits binary compatibility between SMT and SMP systems.

ARMv7 defines a `YIELD` instruction as a specific NOP (No Operation) hint instruction.

The `YIELD` instruction has no effect in a single-threaded system, but developers of such systems can use the instruction to flag its intended use on migration to a multiprocessor or multithreading system. Operating systems can use `YIELD` in places where a yield hint is wanted, knowing that it will be treated as a `NOP` if there is no implementation benefit.

A4.9 Exception-generating and exception-handling instructions

The following instructions are intended specifically to cause a synchronous processor exception to occur:

- The SVC instruction generates a Supervisor Call exception. For more information, see *Supervisor Call (SVC) exception* on page B1-1209.
- The Breakpoint instruction BKPT provides software breakpoints. For more information, see *About debug events* on page C3-2036.
- In a processor that implements the Security Extensions, when executing at PL1 or higher, the SMC instruction generates a Secure Monitor Call exception. For more information, see *Secure Monitor Call (SMC) exception* on page B1-1210.
- In a processor that implements the Virtualization Extensions, in software executing in a Non-secure PL1 mode, the HVC instruction generates a Hypervisor Call exception. For more information, see *Hypervisor Call (HVC) exception* on page B1-1211.

For an exception taken to a PL1 mode:

- The system level variants of the SUBS and LDM instructions perform a return from an exception.

  Note

  The variants of SUBS include MOVS. See the references to SUBS PC, LR in Table A4-15 for more information.

- From ARMv6, the SRS instruction can be used near the start of the handler, to store return information. The RFE instruction can then perform a return from the exception using the stored return information.

In a processor that implements the Virtualization Extensions, the ERET instruction performs a return from an exception taken to Hyp mode.

For more information, see *Exception return* on page B1-1193.

Table A4-15 summarizes the instructions, in the ARM and Thumb instruction sets, for generating or handling an exception. Except for BKPT and SVC, these are system level instructions.

Table A4-15 Exception-generating and exception-handling instructions

Instruction	See
Supervisor Call	*SVC (previously SWI)* on page A8-720
Breakpoint	*BKPT* on page A8-346
Secure Monitor Call	*SMC (previously SMI)* on page B9-2000
Return From Exception	*RFE* on page B9-1998
Subtract (exception return)	*SUBS PC, LR (Thumb)* on page B9-2008 *SUBS PC, LR and related instructions (ARM)* on page B9-2010
Hypervisor Call	*HVC* on page B9-1982
Exception Return	*ERET* on page B9-1980
Load Multiple (exception return)	*LDM (exception return)* on page B9-1984
Store Return State	*SRS (Thumb)* on page B9-2002 *SRS (ARM)* on page B9-2004

A4.10 Coprocessor instructions

There are three types of instruction for communicating with coprocessors. These permit the processor to:

- Initiate a coprocessor data-processing operation. For details see *CDP, CDP2* on page A8-358.
- Transfer ARM core registers to and from coprocessor registers. For details, see:
  - *MCR, MCR2* on page A8-476
  - *MCRR, MCRR2* on page A8-478
  - *MRC, MRC2* on page A8-492
  - *MRRC, MRRC2* on page A8-494.
- Load or store the values of coprocessor registers. For details, see:
  - *LDC, LDC2 (immediate)* on page A8-392
  - *LDC, LDC2 (literal)* on page A8-394
  - *STC, STC2* on page A8-662.

The instruction set distinguishes up to 16 coprocessors with a 4-bit field in each coprocessor instruction, so each coprocessor is assigned a particular number.

Note

One coprocessor can use more than one of the 16 numbers if a large coprocessor instruction set is required.

Coprocessors 10 and 11 are used, together, for Floating-point Extension and some Advanced SIMD Extension functionality. There are different instructions for accessing these coprocessors, of similar types to the instructions for the other coprocessors, that is, to:

- Initiate a coprocessor data-processing operation. For details see *Floating-point data-processing instructions* on page A4-191.
- Transfer ARM core registers to and from coprocessor registers. For details, see *Advanced SIMD and Floating-point register transfer instructions* on page A4-183.
- Load or store the values of coprocessor registers. For details, see *Advanced SIMD and Floating-point load/store instructions* on page A4-181.

Coprocessors execute the same instruction stream as the processor, ignoring non-coprocessor instructions and coprocessor instructions for other coprocessors. Coprocessor instructions that cannot be executed by any coprocessor hardware cause an Undefined Instruction exception.

Coprocessors 8, 9, 12, and 13 are reserved for future use by ARM. Any coprocessor access instruction attempting to access one of these coprocessors is UNDEFINED.

For more information about specific coprocessors see *Coprocessor support* on page A2-94.

A4.11 Advanced SIMD and Floating-point load/store instructions

Table A4-16 summarizes the extension register load/store instructions in the Advanced SIMD and Floating-point (VFP) instruction sets.

Advanced SIMD also provides instructions for loading and storing multiple elements, or structures of elements, see *Element and structure load/store instructions*.

Table A4-16 Extension register load/store instructions

Instruction	See	Operation
Vector Load Multiple	*VLDM* on page A8-922	Load 1-16 consecutive 64-bit registers, Advanced SIMD and Floating-point Load 1-16 consecutive 32-bit registers, Floating-point only
Vector Load Register	*VLDR* on page A8-924	Load one 64-bit register, Advanced SIMD and Floating-point Load one 32-bit register, Floating-point only
Vector Store Multiple	*VSTM* on page A8-1080	Store 1-16 consecutive 64-bit registers, Advanced SIMD and Floating-point Store 1-16 consecutive 32-bit registers, Floating-point only
Vector Store Register	*VSTR* on page A8-1082	Store one 64-bit register, Advanced SIMD and Floating-point Store one 32-bit register, Floating-point only

A4.11.1 Element and structure load/store instructions

Table A4-17 shows the element and structure load/store instructions available in the Advanced SIMD instruction set. Loading and storing structures of more than one element automatically de-interleaves or interleaves the elements, see Figure A4-1 on page A4-182 for an example of de-interleaving. Interleaving is the inverse process.

Table A4-17 Element and structure load/store instructions

Instruction	See
Load single element	
Multiple elements	*VLD1 (multiple single elements)* on page A8-898
To one lane	*VLD1 (single element to one lane)* on page A8-900

Store 3-element structure	
Multiple structures	*VST3 (multiple 3-element structures)* on page A8-1072
From one lane	*VST3 (single 3-element structure from one lane)* on page A8-1074
Store 4-element structure	
Multiple structures	*VST4 (multiple 4-element structures)* on page A8-1076
From one lane	*VST4 (single 4-element structure from one lane)* on page A8-1078

Figure A4-1 shows the de-interleaving of a `VLD3.16` (multiple 3-element structures) instruction:

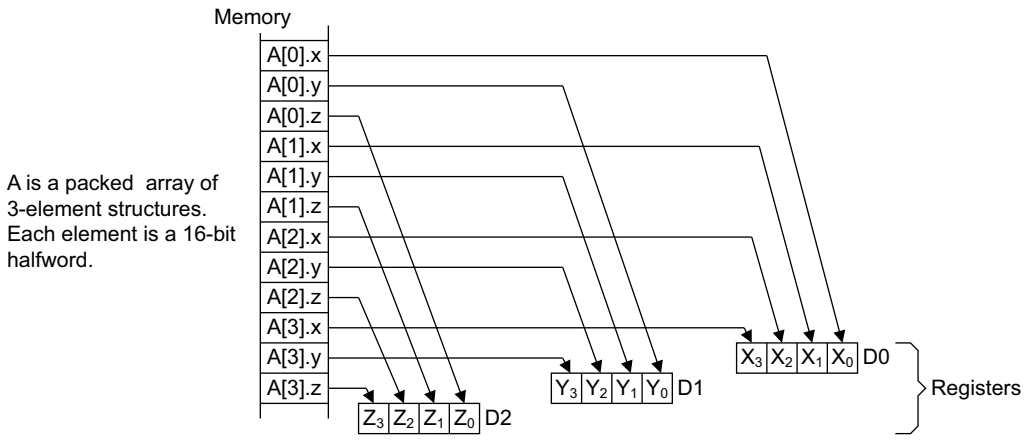

Figure A4-1 De-interleaving an array of 3-element structures

Figure A4-1 shows the `VLD3.16` instruction operating to three 64-bit registers that comprise four 16-bit elements:

- Different instructions in this group would produce similar figures, but operate on different numbers of registers. For example, `VLD4` and `VST4` instructions operate on four registers.
- Different element sizes would produce similar figures but with 8-bit or 32-bit elements.
- These instructions operate only on doubleword (64-bit) registers.

A4.12 Advanced SIMD and Floating-point register transfer instructions

Table A4-18 summarizes the extension register transfer instructions in the Advanced SIMD and Floating-point (VFP) instruction sets. These instructions transfer data from ARM core registers to extension registers, or from extension registers to ARM core registers.

Advanced SIMD vectors, and single-precision and double-precision Floating-point registers, are all views of the same extension register set. For details see *Advanced SIMD and Floating-point Extension registers* on page A2-56.

Table A4-18 Extension register transfer instructions

Instruction	See
Copy element from ARM core register to every element of Advanced SIMD vector	*VDUP (ARM core register)* on page A8-886
Copy byte, halfword, or word from ARM core register to extension register	*VMOV (ARM core register to scalar)* on page A8-940
Copy byte, halfword, or word from extension register to ARM core register	*VMOV (scalar to ARM core register)* on page A8-942
Copy from single-precision Floating-point register to ARM core register, or from ARM core register to single-precision Floating-point register	*VMOV (between ARM core register and single-precision register)* on page A8-944
Copy two words from ARM core registers to consecutive single-precision Floating-point registers, or from consecutive single-precision Floating-point registers to ARM core registers	*VMOV (between two ARM core registers and two single-precision registers)* on page A8-946
Copy two words from ARM core registers to doubleword extension register, or from doubleword extension register to ARM core registers	*VMOV (between two ARM core registers and a doubleword extension register)* on page A8-948

A4.13 Advanced SIMD data-processing instructions

Advanced SIMD data-processing instructions process registers containing vectors of elements of the same type packed together, enabling the same operation to be performed on multiple items in parallel.

Instructions operate on vectors held in 64-bit or 128-bit registers. Figure A4-2 shows an operation on two 64-bit operand vectors, generating a 64-bit vector result.

Note

Figure A4-2 and other similar figures show 64-bit vectors that consist of four 16-bit elements, and 128-bit vectors that consist of four 32-bit elements. Other element sizes produce similar figures, but with one, two, eight, or sixteen operations performed in parallel instead of four.

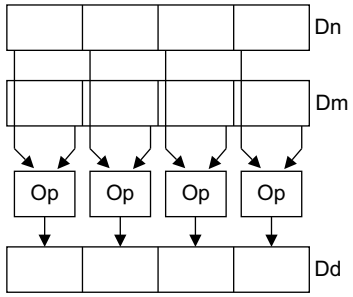

Figure A4-2 Advanced SIMD instruction operating on 64-bit registers

Many Advanced SIMD instructions have variants that produce vectors of elements double the size of the inputs. In this case, the number of elements in the result vector is the same as the number of elements in the operand vectors, but each element, and the whole vector, is double the size.

Figure A4-3 shows an example of an Advanced SIMD instruction operating on 64-bit registers, and generating a 128-bit result.

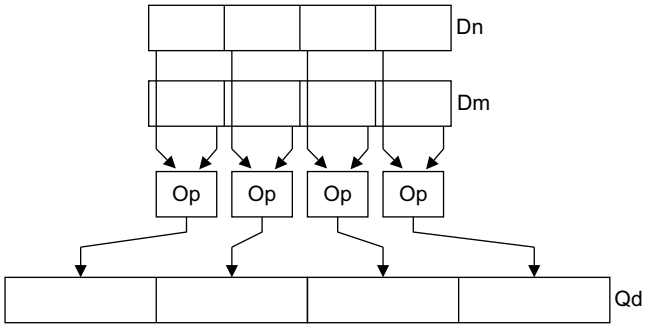

Figure A4-3 Advanced SIMD instruction producing wider result

There are also Advanced SIMD instructions that have variants that produce vectors containing elements half the size of the inputs. Figure A4-4 on page A4-185 shows an example of an Advanced SIMD instruction operating on one 128-bit register, and generating a 64-bit result.

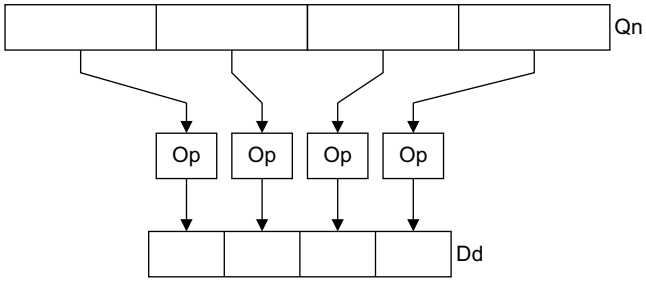

Figure A4-4 Advanced SIMD instruction producing narrower result

Some Advanced SIMD instructions do not conform to these standard patterns. Their operation patterns are described in the individual instruction descriptions.

Advanced SIMD instructions that perform floating-point arithmetic use the ARM standard floating-point arithmetic defined in *Floating-point data types and arithmetic* on page A2-63.

A4.13.1 Advanced SIMD parallel addition and subtraction

Vector Saturating Rounding Doubling Multiply Returning High Half	*VQRDMULH* on page A8-1008
Vector Saturating Doubling Multiply Long	*VQDMULL* on page A8-1002

Advanced SIMD multiply instructions can operate on vectors of:

- 8-bit, 16-bit, or 32-bit unsigned integers.
- 8-bit, 16-bit, or 32-bit signed integers.
- 8-bit polynomials over {0, 1}. `VMUL` and `VMULL` are the only instructions that operate on polynomials. `VMULL` produces a 16-bit polynomial over {0, 1}.
- Single-precision (32-bit) floating-point numbers.

They can also act on one vector and one scalar.

Long instructions have doubleword (64-bit) operands, and produce quadword (128-bit) results. Other Advanced SIMD multiply instructions can have either doubleword or quadword operands, and produce results of the same size.

Floating-point multiply instructions can operate on:

- single-precision (32-bit) floating-point numbers
- double-precision (64-bit) floating-point numbers.

Some Floating-point Extension implementations do not support double-precision numbers.

A4.13.6 Miscellaneous Advanced SIMD data-processing instructions

Table A4-24 shows miscellaneous Advanced SIMD data-processing instructions.

Table A4-24 Miscellaneous Advanced SIMD data-processing instructions

Chapter A5
ARM Instruction Set Encoding

This chapter describes the encoding of the ARM instruction set. It contains the following sections:

- *ARM instruction set encoding* on page A5-194
- *Data-processing and miscellaneous instructions* on page A5-196
- *Load/store word and unsigned byte* on page A5-208
- *Media instructions* on page A5-209
- *Branch, branch with link, and block data transfer* on page A5-214
- *Coprocessor instructions, and Supervisor Call* on page A5-215
- *Unconditional instructions* on page A5-216.

Note

- Architecture variant information in this chapter describes the architecture variant or extension in which the instruction encoding was introduced into the ARM instruction set. *All* means that the instruction encoding was introduced in ARMv4 or earlier, and so is in all variants of the ARM instruction set covered by this manual.
- In the decode tables in this chapter, an entry of - for a field value means the value of the field does not affect the decoding.

A5.1 ARM instruction set encoding

The ARM instruction stream is a sequence of word-aligned words. Each ARM instruction is a single 32-bit word in that stream. The encoding of an ARM instruction is:

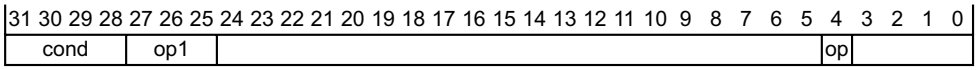

Table A5-1 shows the major subdivisions of the ARM instruction set, determined by bits[31:25, 4].

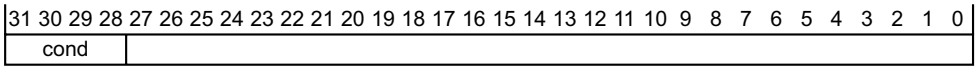
Most ARM instructions can be conditional, with a condition determined by bits[31:28] of the instruction, the `cond` field. For more information see *The condition code field*. This applies to all instructions except those with the cond field equal to `0b1111`.

Table A5-1 ARM instruction encoding

cond	op1	op	Instruction classes
not 1111	00x	-	*Data-processing and miscellaneous instructions* on page A5-196.
	010	-	*Load/store word and unsigned byte* on page A5-208.
	011	0	*Load/store word and unsigned byte* on page A5-208.
		1	*Media instructions* on page A5-209.
	10x	-	*Branch, branch with link, and block data transfer* on page A5-214.
	11x	-	*Coprocessor instructions, and Supervisor Call* on page A5-215. Includes Floating-point instructions and Advanced SIMD data transfers, see Chapter A7 *Advanced SIMD and Floating-point Instruction Encoding*.
1111	-	-	If the cond field is `0b1111`, the instruction can only be executed unconditionally, see *Unconditional instructions* on page A5-216. Includes Advanced SIMD instructions, see Chapter A7 *Advanced SIMD and Floating-point Instruction Encoding*.

A5.1.1 The condition code field

Every conditional instruction contains a 4-bit condition code field, the `cond` field, in bits 31 to 28:



This field contains one of the values `0b0000`-`0b1110`, as shown in Table A8-1 on page A8-288. Most instruction mnemonics can be extended with the letters defined in the *mnemonic extension* column of this table.

If the *always* (`AL`) condition is specified, the instruction is executed irrespective of the value of the condition flags. The absence of a condition code on an instruction mnemonic implies the `AL` condition code.

A5.1.2 UNDEFINED and UNPREDICTABLE instruction set space

An attempt to execute an unallocated instruction results in either:

- Unpredictable behavior. The instruction is described as UNPREDICTABLE.
- An Undefined Instruction exception. The instruction is described as UNDEFINED.

An instruction is UNDEFINED if it is declared as UNDEFINED in an instruction description, or in this chapter.

An instruction is UNPREDICTABLE if:

- it is declared as UNPREDICTABLE in an instruction description or in this chapter
- the pseudocode for that encoding does not indicate that a different special case applies, and a bit marked (0) or (1) in the encoding diagram of an instruction is not 0 or 1 respectively.

For more information about UNDEFINED and UNPREDICTABLE instruction behavior, see *Undefined Instruction exception* on page B1-1205.

Unless otherwise specified:

- ARM instructions introduced in an architecture variant are UNDEFINED in earlier architecture variants.
- ARM instructions introduced in one or more architecture extensions are UNDEFINED in an implementation that does not include any of those extensions.

A5.1.3 The PC and the use of `0b1111` as a register specifier

In ARM instructions, the use of `0b1111` as a register specifier specifies the PC.

Many instructions are UNPREDICTABLE if they use `0b1111` as a register specifier. This is specified by pseudocode in the instruction description.

Note

In ARMv7, ARM deprecates use of the PC as the base register in any store instruction.

A5.1.4 The SP and the use of `0b1101` as a register specifier

In ARM instructions, the use of `0b1101` as a register specifier specifies the SP.

ARM deprecates using SP for any purpose other than as a stack pointer.

A5.2 Data-processing and miscellaneous instructions

The encoding of ARM data-processing instructions, and some miscellaneous, instructions is:

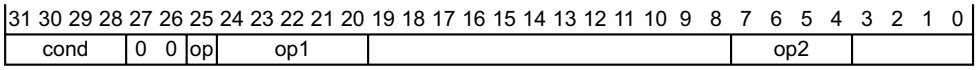


Table A5-2 shows the allocation of encodings in this space.

Table A5-2 Data-processing and miscellaneous instructions

op	op1	op2	Instruction or instruction class	Variant
0	not 10xx0	xxx0	*Data-processing (register)* on page A5-197	-

These instructions all have modified immediate constants, rather than a simple 12-bit binary number. This provides a more useful range of values. For details see *Modified immediate constants in ARM instructions* on page A5-200.

A5.2.4 Modified immediate constants in ARM instructions

The encoding of a modified immediate constant in an ARM instruction is:

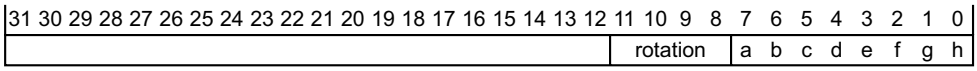

Table A5-6 shows the range of modified immediate constants available in ARM data-processing instructions, and their encoding in the a, b, c, d, e, f, g, and h bits and the rotation field in the instruction.

Table A5-6 Encoding of modified immediates in ARM processing instructions

rotation	<const> [a]
0000	`00000000 00000000 00000000 abcdefgh`
0001	`gh000000 00000000 00000000 00abcdef`
0010	`efgh0000 00000000 00000000 0000abcd`
0011	`cdefgh00 00000000 00000000 000000ab`
0100	`abcdefgh 00000000 00000000 00000000`
. . .	. . 8-bit values shifted to other even-numbered positions . .
1001	`00000000 00abcdef gh000000 00000000`
. . .	. . 8-bit values shifted to other even-numbered positions . .
1110	`00000000 00000000 0000abcd efgh0000`
1111	`00000000 00000000 000000ab cdefgh00`

a. This table shows the immediate constant value in binary form, to relate `abcdefgh` to the encoding diagram. In assembly syntax, the immediate value is specified in the usual way (a decimal number by default).

Note

The range of values available in ARM modified immediate constants is slightly different from the range of values available in 32-bit Thumb instructions. See *Modified immediate constants in Thumb instructions* on page A6-232.

Carry out

A logical instruction with the rotation field set to `0b0000` does not affect APSR.C. Otherwise, a logical flag-setting instruction sets APSR.C to the value of bit[31] of the modified immediate constant.

Constants with multiple encodings

Some constant values have multiple possible encodings. In this case, a UAL assembler must select the encoding with the lowest unsigned value of the rotation field. This is the encoding that appears first in Table A5-6. For example, the constant `#3` must be encoded with (rotation, abcdefgh) == (`0b0000`, `0b00000011`), not (`0b0001`, `0b00001100`), (`0b0010`, `0b00110000`), or (`0b0011`, `0b11000000`).

In particular, this means that all constants in the range 0-255 are encoded with rotation == 0b0000, and permitted constants outside that range are encoded with rotation != 0b0000. A flag-setting logical instruction with a modified immediate constant therefore leaves APSR.C unchanged if the constant is in the range 0-255 and sets it to the most significant bit of the constant otherwise. This matches the behavior of Thumb modified immediate constants for all constants that are permitted in both the ARM and Thumb instruction sets.

An alternative syntax is available for a modified immediate constant that permits the programmer to specify the encoding directly. In this syntax, #<const> is instead written as #<byte>, #<rot>, where:

<byte> is the numeric value of abcdefgh, in the range 0-255

<rot> is twice the numeric value of rotation, an even number in the range 0-30.

This syntax permits all ARM data-processing instructions with modified immediate constants to be disassembled to assembler syntax that assembles to the original instruction.

This syntax also makes it possible to write variants of some flag-setting logical instructions that have different effects on APSR.C to those obtained with the normal #<const> syntax. For example, ANDS R1, R2, #12, #2 has the same behavior as ANDS R1, R2, #3 except that it sets APSR.C to 0 instead of leaving it unchanged. Such variants of flag-setting logical instructions do not have equivalents in the Thumb instruction set, and ARM deprecates their use.

Operation of modified immediate constants, ARM instructions

```
// ARMExpandImm()
// ==============

bits(32) ARMExpandImm(bits(12) imm12)

    // APSR.C argument to following function call does not affect the imm32 result.
    (imm32, -) = ARMExpandImm_C(imm12, APSR.C);

    return imm32;
// ARMExpandImm_C()
// ================

(bits(32), bit) ARMExpandImm_C(bits(12) imm12, bit carry_in)

    unrotated_value = ZeroExtend(imm12<7:0>, 32);
    (imm32, carry_out) = Shift_C(unrotated_value, SRType_ROR, 2*UInt(imm12<11:8>), carry_in);

    return (imm32, carry_out);
```

A5.2.5 Multiply and multiply accumulate

The encoding of ARM multiply and multiply accumulate instructions is:

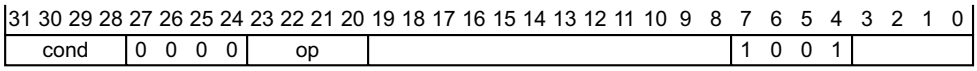

Table A5-7 shows the allocation of encodings in this space.

Table A5-7 Multiply and multiply accumulate instructions

op	Instruction	See	Variant
000x	Multiply	*MUL* on page A8-502	All
001x	Multiply Accumulate	*MLA* on page A8-480	All
0100	Unsigned Multiply Accumulate Accumulate Long	*UMAAL* on page A8-774	v6

11	Saturating Double and Subtract	*QDSUB* on page A8-550

A5.2.7 Halfword multiply and multiply accumulate

The encoding of ARM halfword multiply and multiply accumulate instructions is:

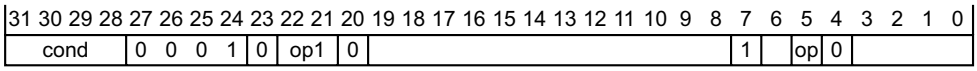

Table A5-9 shows the allocation of encodings in this space.

These encodings are signed multiply (SMUL) and signed multiply accumulate (SMLA) instructions, operating on 16-bit values, or mixed 16-bit and 32-bit values. The results and accumulators are 32-bit or 64-bit.

These encodings are all available in ARMv5TE and above, and are UNDEFINED in earlier variants of the architecture.

Table A5-9 Halfword multiply and multiply accumulate instructions

op1	op	Instruction	See
00	-	Signed 16-bit multiply, 32-bit accumulate	*SMLABB, SMLABT, SMLATB, SMLATT* on page A8-620

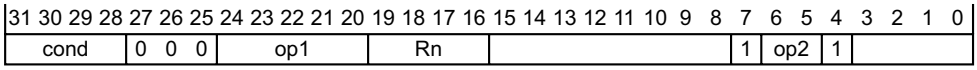
A5.2.8 Extra load/store instructions

The encoding of extra ARM load/store instructions is:



If (op2 == 0b00) or (op1 == 0b0xx11) or (op1 == 0b0xx10 AND op2 == 0b0x) then see *Data-processing and miscellaneous instructions* on page A5-196.

Otherwise, Table A5-10 shows the allocation of encodings in this space.

Table A5-10 Extra load/store instructions

op2	op1	Rn	Instruction	See	Variant
01	xx0x0	-	Store Halfword	*STRH (register)* on page A8-702	All

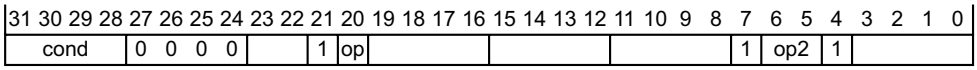
		1111	Load Signed Halfword	*LDRSH (literal)* on page A8-460	All

A5.2.9 Extra load/store instructions, unprivileged

The encoding of unprivileged extra ARM load/store instructions is:



If op2 == `0b00` then see *Data-processing and miscellaneous instructions* on page A5-196.

If (op == `0b0` AND op2 == `0b1x`) then see *Extra load/store instructions* on page A5-203.

Otherwise, Table A5-11 shows the allocation of encodings in this space.

Table A5-11 Extra load/store instructions, unprivileged

op2	op	Instruction	See	Variant
01	0	Store Halfword Unprivileged	*STRHT* on page A8-704	v6T2
	1	Load Halfword Unprivileged	*LDRHT* on page A8-448	v6T2
10	1	Load Signed Byte Unprivileged	*LDRSBT* on page A8-456	v6T2
11	1	Load Signed Halfword Unprivileged	*LDRSHT* on page A8-464	v6T2

A5.2.10 Synchronization primitives

The encoding of ARM synchronization primitive instructions is:

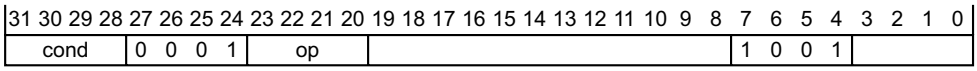


Table A5-12 shows the allocation of encodings in this space.

Other encodings in this space are UNDEFINED.

Table A5-12 Synchronization primitives

op	Instruction	See	Variant
0x00	Swap Word, Swap Byte	*SWP, SWPB* on page A8-722 [a]	All
1000	Store Register Exclusive	*STREX* on page A8-690	v6
1001	Load Register Exclusive	*LDREX* on page A8-432	v6
1010	Store Register Exclusive Doubleword	*STREXD* on page A8-694	v6K

1111	Load Register Exclusive Halfword	*LDREXH* on page A8-438	v6K

a. ARM deprecates the use of these instructions.

A5.2.11 MSR (immediate), and hints

The encoding of ARM `MSR` (immediate) and hint instructions is:

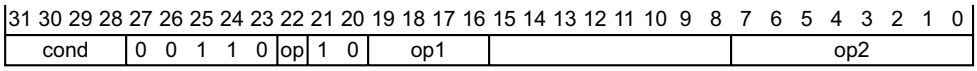

Table A5-13 shows the allocation of encodings in this space. Encodings with `op` set to 0, `op1` set to `0b000`, and a value of `op2` that is not shown in the table, are unallocated hints and behave as if `op2` is set to `0b00000000`. These unallocated hint encodings are reserved and software must not use them.

Table A5-13 MSR (immediate), and hints

op	op1	op2	Instruction	See	Variant

Chapter A6
Thumb Instruction Set Encoding

This chapter introduces the Thumb instruction set and describes how it uses the ARM programmers' model. It contains the following sections:

- *Thumb instruction set encoding* on page A6-220
- *16-bit Thumb instruction encoding* on page A6-223
- *32-bit Thumb instruction encoding* on page A6-230.

For details of the differences between the Thumb and ThumbEE instruction sets see Chapter A9 *The ThumbEE Instruction Set*.

Note

- Architecture variant information in this chapter describes the architecture variant or extension in which the instruction encoding was introduced into the Thumb instruction set.
- In the decode tables in this chapter, an entry of - for a field value means the value of the field does not affect the decoding.

A6.1 Thumb instruction set encoding

The Thumb instruction stream is a sequence of halfword-aligned halfwords. Each Thumb instruction is either a single 16-bit halfword in that stream, or a 32-bit instruction consisting of two consecutive halfwords in that stream.

If the value of bits[15:11] of the halfword being decoded is one of the following, the halfword is the first halfword of a 32-bit instruction:

- `0b11101`
- `0b11110`
- `0b11111`.

Otherwise, the halfword is a 16-bit instruction.

For details of the encoding of 16-bit Thumb instructions see *16-bit Thumb instruction encoding* on page A6-223.

For details of the encoding of 32-bit Thumb instructions see *32-bit Thumb instruction encoding* on page A6-230.

A6.1.1 UNDEFINED and UNPREDICTABLE instruction set space

An attempt to execute an unallocated instruction results in either:

- Unpredictable behavior. The instruction is described as UNPREDICTABLE.
- An Undefined Instruction exception. The instruction is described as UNDEFINED.

An instruction is UNDEFINED if it is declared as UNDEFINED in an instruction description, or in this chapter.

An instruction is UNPREDICTABLE if:

- a bit marked (0) in the encoding diagram of an instruction is not 0, and the pseudocode for that encoding does not indicate that a different special case applies when that bit is not 0
- a bit marked (1) in the encoding diagram of an instruction is not 1, and the pseudocode for that encoding does not indicate that a different special case applies when that bit is not 1
- it is declared as UNPREDICTABLE in an instruction description or in this chapter.

For more information about UNDEFINED and UNPREDICTABLE instruction behavior, see *Undefined Instruction exception* on page B1-1205.

Unless otherwise specified:

- Thumb instructions introduced in an architecture variant are either UNPREDICTABLE or UNDEFINED in earlier architecture variants.
- A Thumb instruction that is provided by one or more of the architecture extensions is either UNPREDICTABLE or UNDEFINED in an implementation that does not include any of those extensions.

In both cases, the instruction is UNPREDICTABLE if it is a 32-bit instruction in an architecture variant before ARMv6T2, and UNDEFINED otherwise.

A6.1.2 Use of the PC, and use of `0b1111` as a register specifier

The use of `0b1111` as a register specifier is not normally permitted in Thumb instructions. When a value of `0b1111` is permitted, a variety of meanings is possible. For register reads, these meanings include:

- Read the PC value, that is, the address of the current instruction + 4. The base register of the table branch instructions `TBB` and `TBH` can be the PC. This means branch tables can be placed in memory immediately after the instruction.

  Note

  In ARMv7, ARM deprecates use of the PC as the base register in the `STC` instruction.

- Read the word-aligned PC value, that is, the address of the current instruction + 4, with bits[1:0] forced to zero. The base register of LDC, LDR, LDRB, LDRD (pre-indexed, no writeback), LDRH, LDRSB, and LDRSH instructions can be the word-aligned PC. This provides PC-relative data addressing. In addition, some encodings of the ADD and SUB instructions permit their source registers to be 0b1111 for the same purpose.
- Read zero. This is done in some cases when one instruction is a special case of another, more general instruction, but with one operand zero. In these cases, the instructions are listed on separate pages, with a special case in the pseudocode for the more general instruction cross-referencing the other page.

For register writes, these meanings include:

- The PC can be specified as the destination register of an LDR instruction. This is done by encoding Rt as 0b1111. The loaded value is treated as an address, and the effect of execution is a branch to that address. Bit[0] of the loaded value selects whether to execute ARM or Thumb instructions after the branch.
- Some other instructions write the PC in similar ways. An instruction can specify that the PC is written:
  - implicitly, for example, branch instructions
  - explicitly by a register specifier of 0b1111, for example 16-bit MOV (register) instructions
  - explicitly by using a register mask, for example LDM instructions.

  The address to branch to can be:
  - a loaded value, for example, RFE
  - a register value, for example, BX
  - the result of a calculation, for example, TBB or TBH.

  The method of choosing the instruction set used after the branch can be:
  - similar to the LDR case, for example, LDM or BX
  - a fixed instruction set other than the one currently being used, for example, the immediate form of BLX
  - unchanged, for example, branch instructions or 16-bit MOV (register) instructions
  - set from the {J, T} bits of the SPSR, for RFE and SUBS PC, LR, #imm8.
- Discard the result of a calculation. This is done in some cases when one instruction is a special case of another, more general instruction, but with the result discarded. In these cases, the instructions are listed on separate pages, with a special case in the pseudocode for the more general instruction cross-referencing the other page.
- If the destination register specifier of an LDRB, LDRH, LDRSB, or LDRSH instruction is 0b1111, the instruction is a memory hint instead of a load operation.
- If the destination register specifier of an MRC instruction is 0b1111, bits[31:28] of the value transferred from the coprocessor are written to the N, Z, C, and V condition flags in the APSR, and bits[27:0] are discarded.

A6.1.3 Use of the SP, and use of 0b1101 as a register specifier

R13 is defined in the Thumb instruction set so that its use is primarily as a stack pointer, and R13 is normally identified as SP in Thumb instructions. In 32-bit Thumb instructions, if software uses R13 as a general-purpose register beyond the architecturally defined constraints described in this section, the results are UNPREDICTABLE.

The restrictions applicable to R13 are described in:

- *R13[1:0] definition*
- *32-bit Thumb instruction support for R13* on page A6-222.

See also *16-bit Thumb instruction support for R13* on page A6-222.

R13[1:0] definition

Bits[1:0] of R13 are SBZP. Writing a nonzero value to bits[1:0] causes UNPREDICTABLE behavior.

32-bit Thumb instruction support for R13

R13 instruction support is restricted to the following:

- R13 as the source or destination register of a MOV instruction. Only register to register transfers without shifts are supported, with no flag-setting:

```
MOV     SP, <Rm>
MOV     <Rn>, SP
```

- Using the following instructions to adjust R13 up or down by a multiple of 4:

```
ADD{W}  SP, SP, #<imm>
SUB{W}  SP, SP, #<imm>
ADD     SP, SP, <Rm>
ADD     SP, SP, <Rm>, LSL #<n>      ; For <n> = 1, 2, 3
SUB     SP, SP, <Rm>
SUB     SP, SP, <Rm>, LSL #<n>      ; For <n> = 1, 2, 3
```

- R13 as a base register <Rn> of any load/store instruction. This supports SP-based addressing for load, store, or memory hint instructions, with positive or negative offsets, with and without writeback.

- R13 as the first operand <Rn> in any ADD{S}, CMN, CMP, or SUB{S} instruction. The add and subtract instructions support SP-based address generation, with the address going into an ARM core register, R0-R12 or R14. CMN and CMP are useful for stack checking in some circumstances.

- R13 as the transferred register <Rt> in any LDR or STR instruction.

16-bit Thumb instruction support for R13

For 16-bit data-processing instructions that affect high registers, R13 can only be used as described in *32-bit Thumb instruction support for R13*. ARM deprecates any other use. This affects the high register forms of CMP and ADD, where ARM deprecates the use of R13 as <Rm>.

A6.2 16-bit Thumb instruction encoding

The encoding of a 16-bit Thumb instruction is:

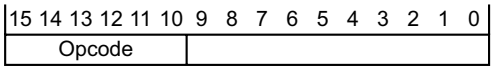

Table A6-1 shows the allocation of 16-bit instruction encodings.

Table A6-1 16-bit Thumb instruction encoding

Opcode	Instruction or instruction class	Variant
00xxxx	*Shift (immediate), add, subtract, move, and compare* on page A6-224	-
010000	*Data-processing* on page A6-225	-
010001	*Special data instructions and branch and exchange* on page A6-226	-
01001x	Load from Literal Pool, see *LDR (literal)* on page A8-410	v4T
0101xx 011xxx 100xxx	*Load/store single data item* on page A6-227	-
10100x	Generate PC-relative address, see *ADR* on page A8-322	v4T
10101x	Generate SP-relative address, see *ADD (SP plus immediate)* on page A8-316	v4T
1011xx	*Miscellaneous 16-bit instructions* on page A6-228	-
11000x	Store multiple registers, see *STM (STMIA, STMEA)* on page A8-664 [a]	v4T
11001x	Load multiple registers, see *LDM/LDMIA/LDMFD (Thumb)* on page A8-396 [a]	v4T
1101xx	*Conditional branch, and Supervisor Call* on page A6-229	-
11100x	Unconditional Branch, see *B* on page A8-334	v4T

a. In ThumbEE, 16-bit load/store multiple instructions are not available. This encoding is used for special ThumbEE instructions. For details see Chapter A9 *The ThumbEE Instruction Set*.

A6.2.1 Shift (immediate), add, subtract, move, and compare

The encoding of 16-bit Thumb shift (immediate), add, subtract, move, and compare instructions is:

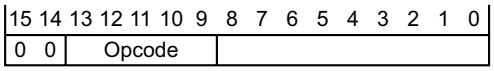

Table A6-2 shows the allocation of encodings in this space.

All these instructions are available since the Thumb instruction set was introduced in ARMv4T.

Table A6-2 16-bit Thumb shift (immediate), add, subtract, move, and compare instructions

Opcode	Instruction	See
000xx	Logical Shift Left[a]	*LSL (immediate)* on page A8-468
001xx	Logical Shift Right	*LSR (immediate)* on page A8-472

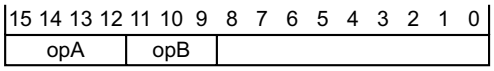
1001 101x	Move High Registers	*MOV (register, Thumb)* on page A8-486	v4T
110x	Branch and Exchange	*BX* on page A8-352	v4T
111x	Branch with Link and Exchange	*BLX (register)* on page A8-350	v5T [a]

a. UNPREDICTABLE in earlier variants.

A6.2.4 Load/store single data item

The encoding of 16-bit Thumb instructions that load or store a single data item is:



These instructions have one of the following values of opA:

- `0b0101`
- `0b011x`
- `0b100x`.

Table A6-5 shows the allocation of encodings in this space.

All these instructions are available since the Thumb instruction set was introduced in ARMv4T.

Table A6-5 16-bit Thumb Load/store single data item instructions

opA	opB	Instruction	See
0101	000	Store Register	*STR (register)* on page A8-676
	001	Store Register Halfword	*STRH (register)* on page A8-702

A6.2.6 Conditional branch, and Supervisor Call

The encoding of 16-bit Thumb conditional branch and Supervisor Call instructions is:

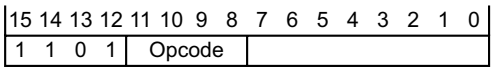

Table A6-8 shows the allocation of encodings in this space.

All these instructions are available since the Thumb instruction set was introduced in ARMv4T.

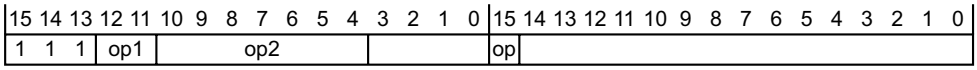
Table A6-8 Conditional branch and Supervisor Call instructions

Opcode	Instruction	See
not 111x	Conditional branch	*B* on page A8-334
1110	Permanently UNDEFINED	*UDF* on page A8-758[a]
1111	Supervisor Call	*SVC (previously SWI)* on page A8-720

a. Issue C.a of this manual first defines an assembler mnemonic for this encoding.

A6.3 32-bit Thumb instruction encoding

The encoding of a 32-bit Thumb instruction is:



If op1 == `0b00`, a 16-bit instruction is encoded, see *16-bit Thumb instruction encoding* on page A6-223.

Otherwise, Table A6-9 shows the allocation of encodings in this space.

Table A6-9 32-bit Thumb instruction encoding

	1xxxxxx	-	*Coprocessor, Advanced SIMD, and Floating-point instructions* on page A6-251

A6.3.1 Data-processing (modified immediate)

The encoding of the 32-bit Thumb data-processing (modified immediate) instructions is:

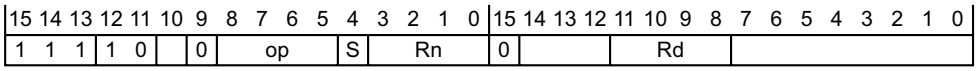

Table A6-10 shows the allocation of encodings in this space. Other encodings in this space are UNDEFINED.

These encodings are all available in ARMv6T2 and above.

Table A6-10 32-bit modified immediate data-processing instructions

op	Rn	Rd:S	Instruction	See
0000	-	not 11111	Bitwise AND	*AND (immediate)* on page A8-324
		11111	Test	*TST (immediate)* on page A8-744
0001	-	-	Bitwise Bit Clear	*BIC (immediate)* on page A8-340
0010	not 1111	-	Bitwise OR	*ORR (immediate)* on page A8-516
	1111	-	Move	*MOV (immediate)* on page A8-484
0011	not 1111	-	Bitwise OR NOT	*ORN (immediate)* on page A8-512
	1111	-	Bitwise NOT	*MVN (immediate)* on page A8-504
0100	-	not 11111	Bitwise Exclusive OR	*EOR (immediate)* on page A8-382
		11111	Test Equivalence	*TEQ (immediate)* on page A8-738
1000	-	not 11111	Add	*ADD (immediate, Thumb)* on page A8-306
		11111	Compare Negative	*CMN (immediate)* on page A8-364
1010	-	-	Add with Carry	*ADC (immediate)* on page A8-300
1011	-	-	Subtract with Carry	*SBC (immediate)* on page A8-592
1101	-	not 11111	Subtract	*SUB (immediate, Thumb)* on page A8-708
		11111	Compare	*CMP (immediate)* on page A8-370
1110	-	-	Reverse Subtract	*RSB (immediate)* on page A8-574

These instructions all have modified immediate constants, rather than a simple 12-bit binary number. This provides a more useful range of values. For details see *Modified immediate constants in Thumb instructions* on page A6-232.

A6.3.2 Modified immediate constants in Thumb instructions

The encoding of a modified immediate constant in a 32-bit Thumb instruction is:

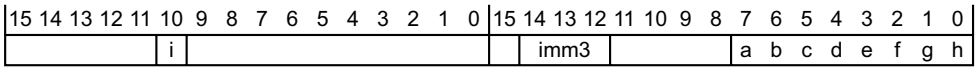

Table A6-11 shows the range of modified immediate constants available in Thumb data-processing instructions, and their encoding in the a, b, c, d, e, f, g, h, and i bits, and the imm3 field, in the instruction.

Table A6-11 Encoding of modified immediates in Thumb data-processing instructions

i:imm3:a	<const> [a]
0000x	`00000000 00000000 00000000 abcdefgh`
0001x	`00000000 abcdefgh 00000000 abcdefgh` [b]
0010x	`abcdefgh 00000000 abcdefgh 00000000` [b]
0011x	`abcdefgh abcdefgh abcdefgh abcdefgh` [b]
01000	`1bcdefgh 00000000 00000000 00000000`
01001	`01bcdefg h0000000 00000000 00000000` [c]
01010	`001bcdef gh000000 00000000 00000000`
01011	`0001bcde fgh00000 00000000 00000000` [c]
.	.
.	. 8-bit values shifted to other positions
.	.
11101	`00000000 00000000 000001bc defgh000` [c]
11110	`00000000 00000000 0000001b cdefgh00`
11111	`00000000 00000000 00000001 bcdefgh0` [c]

a. This table shows the immediate constant value in binary form, to relate `abcdefgh` to the encoding diagram. In assembly syntax, the immediate value is specified in the usual way (a decimal number by default).

b. Not available in ARM instructions. UNPREDICTABLE if abcdefgh == 00000000.

c. Not available in ARM instructions if `h` == 1.

Note

As the footnotes to Table A6-11 show, the range of values available in Thumb modified immediate constants is slightly different from the range of values available in ARM instructions. See *Modified immediate constants in ARM instructions* on page A5-200 for the ARM values.

Carry out

A logical instruction with i:imm3:a == '00xxx' does not affect the Carry flag. Otherwise, a logical flag-setting instruction sets the Carry flag to the value of bit[31] of the modified immediate constant.

Operation of modified immediate constants, Thumb instructions

```
// ThumbExpandImm()
// ================

bits(32) ThumbExpandImm(bits(12) imm12)

    // APSR.C argument to following function call does not affect the imm32 result.
    (imm32, -) = ThumbExpandImm_C(imm12, APSR.C);

    return imm32;

// ThumbExpandImm_C()
// ==================

(bits(32), bit) ThumbExpandImm_C(bits(12) imm12, bit carry_in)

    if imm12<11:10> == '00' then

        case imm12<9:8> of
            when '00'
                imm32 = ZeroExtend(imm12<7:0>, 32);
            when '01'
                if imm12<7:0> == '00000000' then UNPREDICTABLE;
                imm32 = '00000000' : imm12<7:0> : '00000000' : imm12<7:0>;
            when '10'
                if imm12<7:0> == '00000000' then UNPREDICTABLE;
                imm32 = imm12<7:0> : '00000000' : imm12<7:0> : '00000000';
            when '11'
                if imm12<7:0> == '00000000' then UNPREDICTABLE;
                imm32 = imm12<7:0> : imm12<7:0> : imm12<7:0> : imm12<7:0>;
        carry_out = carry_in;

    else

        unrotated_value = ZeroExtend('1':imm12<6:0>, 32);
        (imm32, carry_out) = ROR_C(unrotated_value, UInt(imm12<11:7>));

    return (imm32, carry_out);
```

A6.3.3 Data-processing (plain binary immediate)

The encoding of the 32-bit Thumb data-processing (plain binary immediate) instructions is:

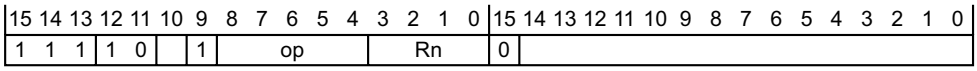

Table A6-12 shows the allocation of encodings in this space. Other encodings in this space are UNDEFINED.

These encodings are all available in ARMv6T2 and above.

Table A6-12 32-bit unmodified immediate data-processing instructions

1x0	-	-	-	Branch with Link and Exchange	*BL, BLX (immediate)* on page A8-348	v5T [c]
1x1	-	-	-	Branch with Link	*BL, BLX (immediate)* on page A8-348	v4T

a. v7VE, that is, ARMv7 with the Virtualization Extensions, first defines ERET as an assembler mnemonic for this encoding. From ARMv6T2 this is an encoding for *SUBS PC, LR (Thumb)* on page B9-2008 with an imm8 value of zero. The Virtualization Extensions do not change the behavior of the encoded instruction when it is executed at PL1.

b. Issue C.a of this manual first defines an assembler mnemonic for this encoding.

c. UNDEFINED in ARMv4T.

Change Processor State, and hints

The encoding of 32-bit Thumb Change Processor State and hint instructions is:

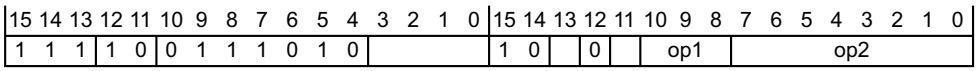

Table A6-14 shows the allocation of encodings in this space. Encodings with `op1` set to `0b000` and a value of `op2` that is not shown in the table are unallocated hints, and behave as if `op2` is set to `0b00000000`. These unallocated hint encodings are reserved and software must not use them.

Table A6-14 Change Processor State, and hint instructions

op1	op2	Instruction	See	Variant
not 000	-	Change Processor State	*CPS (Thumb)* on page B9-1976	v6T2

Chapter A7
Advanced SIMD and Floating-point Instruction Encoding

This chapter gives an overview of the Advanced SIMD and Floating-point (VFP) instruction sets. It contains the following sections:

- *Overview* on page A7-254
- *Advanced SIMD and Floating-point instruction syntax* on page A7-255
- *Register encoding* on page A7-259
- *Advanced SIMD data-processing instructions* on page A7-261
- *Floating-point data-processing instructions* on page A7-272
- *Extension register load/store instructions* on page A7-274
- *Advanced SIMD element or structure load/store instructions* on page A7-275
- *8, 16, and 32-bit transfer between ARM core and extension registers* on page A7-278
- *64-bit transfers between ARM core and extension registers* on page A7-279.

Note

- The Advanced SIMD architecture extension, its associated implementations, and supporting software, are commonly referred to as NEON™ technology.
- In the decode tables in this chapter, an entry of - for a field value means the value of the field does not affect the decoding.

A7.1 Overview

All Advanced SIMD and Floating-point instructions are available in both ARM state and Thumb state.

A7.1.1 Advanced SIMD

The following sections describe the classes of instruction in the Advanced SIMD Extension:

- *Advanced SIMD data-processing instructions* on page A7-261
- *Advanced SIMD element or structure load/store instructions* on page A7-275
- *Extension register load/store instructions* on page A7-274
- *8, 16, and 32-bit transfer between ARM core and extension registers* on page A7-278
- *64-bit transfers between ARM core and extension registers* on page A7-279.

A7.1.2 Floating-point

The following sections describe the classes of instruction in the Floating-point Extension:

- *Extension register load/store instructions* on page A7-274
- *8, 16, and 32-bit transfer between ARM core and extension registers* on page A7-278
- *64-bit transfers between ARM core and extension registers* on page A7-279
- *Floating-point data-processing instructions* on page A7-272.

A7.2 Advanced SIMD and Floating-point instruction syntax

Advanced SIMD and Floating-point (VFP) instructions use the general conventions of the ARM instruction set.

Advanced SIMD and Floating-point data-processing instructions use the following general format:

```
V{<modifier>}<operation>{<shape>}{<c>}{<q>}{.<dt>}  {<dest>,} <src1>, <src2>
```

All Advanced SIMD and Floating-point instructions begin with a `V`. This distinguishes Advanced SIMD vector and Floating-point instructions from ARM scalar instructions.

The main operation is specified in the `<operation>` field. It is usually a three letter mnemonic the same as or similar to the corresponding scalar integer instruction.

The `<c>` and `<q>` fields are standard assembler syntax fields. For details see *Standard assembler syntax fields* on page A8-287.

A7.2.1 Advanced SIMD instruction modifiers

The `<modifier>` field provides additional variants of some instructions. Table A7-1 provides definitions of the modifiers. Modifiers are not available for every instruction.

Table A7-1 Advanced SIMD instruction modifiers

<modifier>	Meaning
Q	The operation uses saturating arithmetic.
R	The operation performs rounding.
D	The operation doubles the result (before accumulation, if any).
H	The operation halves the result.

A7.2.2 Advanced SIMD operand shapes

The `<shape>` field provides additional variants of some instructions. Table A7-2 provides definitions of the shapes. Operand shapes are not available for every instruction.

Table A7-2 Advanced SIMD operand shapes

<shape>	Meaning	Typical register shape	
(none)	The operands and result are all the same width.	Dd, Dn, Dm	Qd, Qn, Qm
L	Long operation - result is twice the width of both operands	Qd, Dn, Dm	
N	Narrow operation - result is half the width of both operands	Dd, Qn, Qm	
W	Wide operation - result and first operand are twice the width of the second operand	Qd, Qn, Dm	

Note

- Some assemblers support a Q shape specifier, that requires all operands to be Q registers. An example of using this specifier is `VADDQ.S32  q0, q1, q2`. This is not standard UAL, and ARM recommends that programmers do not use a Q shape specifier.
- A disassembler must not generate any shape specifier not shown in Table A7-2.

A7.2.3 Data type specifiers

The <dt> field normally contains one data type specifier. Unless the assembler syntax description for the instruction indicates otherwise, this indicates the data type contained in:

- the second operand, if any
- the operand, if there is no second operand
- the result, if there are no operand registers.

The data types of the other operand and result are implied by the <dt> field combined with the instruction shape. For information about data type formats see *Data types supported by the Advanced SIMD Extension* on page A2-59.

In the instruction syntax descriptions in Chapter A8 *Instruction Details*, the <dt> field is usually specified as a single field. However, where more convenient, it is sometimes specified as a concatenation of two fields, <type><size>.

Syntax flexibility

There is some flexibility in the data type specifier syntax:

- Software can specify three data types, specifying the result and both operand data types. For example:

  `VSUBW.I16.I16.S8 Q3, Q5, D0` instead of `VSUBW.S8 Q3, Q5, D0`

- Software can specify two data types, specifying the data types of the two operands. The data type of the result is implied by the instruction shape. For example:

  `VSUBW.I16.S8 Q3, Q5, D0` instead of `VSUBW.S8 Q3, Q5, D0`

- Software can specify two data types, specifying the data types of the single operand and the result. For example:

  `VMOVN.I16.I32 D0, Q1` instead of `VMOVN.I32 D0, Q1`

- Where an instruction requires a less specific data type, software can instead specify a more specific type, as shown in Table A7-3.

- Where an instruction does not require a data type, software can provide one.

- The `F32` data type can be abbreviated to `F`.

- The `F64` data type can be abbreviated to `D`.

In all cases, if software provides additional information, the additional information must match the instruction shape. Disassembly does not regenerate this additional information.

Table A7-3 Data type specification flexibility

Specified data type	Permitted more specific data types				
None	Any				
.I<size>	-	.S<size>	.U<size>	-	-
.8	.I8	.S8	.U8	.P8	-
.16	.I16	.S16	.U16	.P16	.F16
.32	.I32	.S32	.U32	-	.F32 or .F
.64	.I64	.S64	.U64	-	.F64 or .D

A7.2.4 Register specifiers

The <dest>, <src1>, and <src2> fields contain register specifiers, or in some cases scalar specifiers or register lists. Table A7-4 shows the register and scalar specifier formats that appear in the instruction descriptions.

If <dest> is omitted, it is the same as <src1>.

Table A7-4 Advanced SIMD and Floating-point register specifier formats

<specifier>	Usual meaning [a]	Used in
<Qd>	A quadword destination register for the result vector.	Advanced SIMD
<Qn>	A quadword source register for the first operand vector.	Advanced SIMD
<Qm>	A quadword source register for the second operand vector.	Advanced SIMD
<Dd>	A doubleword destination register for the result vector.	Both
<Dn>	A doubleword source register for the first operand vector.	Both
<Dm>	A doubleword source register for the second operand vector.	Both
<Sd>	A singleword destination register for the result vector.	Floating-point
<Sn>	A singleword source register for the first operand vector.	Floating-point
<Sm>	A singleword source register for the second operand vector.	Floating-point
<Dd[x]>	A destination scalar for the result. Element x of vector <Dd>.	Advanced SIMD
<Dn[x]>	A source scalar for the first operand. Element x of vector <Dn>.	Both [b]
<Dm[x]>	A source scalar for the second operand. Element x of vector <Dm>.	Advanced SIMD
<Rt>	An ARM core register, used for a source or destination address.	Both
<Rt2>	An ARM core register, used for a source or destination address.	Both
<Rn>	An ARM core register, used as a load or store base address.	Both
<Rm>	An ARM core register, used as a post-indexed address source.	Both

a. In some instructions the roles of registers are different.

b. In the Floating-point Extension, <Dn[x]> is used only in VMOV (scalar to ARM core register), see *VMOV (scalar to ARM core register)* on page A8-942.

A7.2.5 Register lists

A register list is a list of register specifiers separated by commas and enclosed in brackets { and }. There are restrictions on what registers can appear in a register list. These restrictions are described in the individual instruction descriptions. Table A7-5 shows some register list formats, with examples of actual register lists corresponding to those formats.

Note

Register lists must not wrap around the end of the register bank.

Syntax flexibility

There is some flexibility in the register list syntax:

- Where a register list contains consecutive registers, they can be specified as a range, instead of listing every register, for example `{D0-D3}` instead of `{D0, D1, D2, D3}`.
- Where a register list contains an even number of consecutive doubleword registers starting with an even numbered register, it can be written as a list of quadword registers instead, for example `{Q1, Q2}` instead of `{D2-D5}`.
- Where a register list contains only one register, the enclosing braces can be omitted, for example `VLD1.8 D0, [R0]` instead of `VLD1.8 {D0}, [R0]`.

Table A7-5 Example register lists

Format	Example	Alternative
`{<Dd>}`	`{D3}`	`D3`
`{<Dd>, <Dd+1>, <Dd+2>}`	`{D3, D4, D5}`	`{D3-D5}`
`{<Dd[x]>, <Dd+2[x]}`	`{D0[3], D2[3]}`	-
`{<Dd[]>}`	`{D7[]}`	`D7[]`

A7.3 Register encoding

An Advanced SIMD register is either:

- *quadword*, meaning it is 128 bits wide
- *doubleword*, meaning it is 64 bits wide.

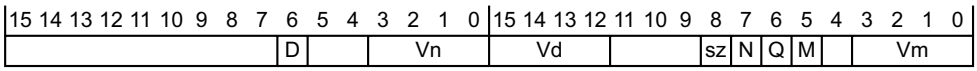
Some instructions have options for either doubleword or quadword registers. This is normally encoded in Q, bit[6], as Q = 0 for doubleword operations, or Q = 1 for quadword operations.

A Floating-point register is either:

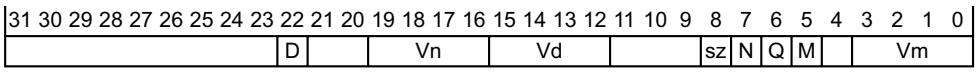
- double-precision, meaning it is 64 bits wide
- single-precision, meaning it is 32 bits wide.

This is encoded in the sz field, bit[8], as sz = 1 for double-precision operations, or sz = 0 for single-precision operations.

The Thumb instruction encoding of Advanced SIMD or Floating-point registers is:



The ARM instruction encoding of Advanced SIMD or Floating-point registers is:



Some instructions use only one or two registers, and use the unused register fields as additional opcode bits.

Table A7-6 shows the encodings for the registers.

Table A7-6 Encoding of register numbers

Register mnemonic	Usual usage	Register number encoded in[a]	Notes[a]	Used in
<Qd>	Destination (quadword)	D, Vd (bits[22, 15:13])	bit[12] == 0[b]	Advanced SIMD
<Qn>	First operand (quadword)	N, Vn (bits[7, 19:17])	bit[16] == 0[b]	Advanced SIMD
<Qm>	Second operand (quadword)	M, Vm (bits[5, 3:1])	bit[0] == 0[b]	Advanced SIMD
<Dd>	Destination (doubleword)	D, Vd (bits[22, 15:12])	-	Both
<Dn>	First operand (doubleword)	N, Vn (bits[7, 19:16])	-	Both
<Dm>	Second operand (doubleword)	M, Vm (bits[5, 3:0])	-	Both
<Sd>	Destination (single-precision)	Vd, D (bits[15:12, 22])	-	Floating-point
<Sn>	First operand (single-precision)	Vn, N (bits[19:16, 7])	-	Floating-point
<Sm>	Second operand (single-precision)	Vm, M (bits[3:0, 5])	-	Floating-point

a. Bit numbers given for the ARM instruction encoding. See the figures in this section for the equivalent bits in the Thumb encoding.

b. If this bit is 1, the instruction is UNDEFINED.

A7.3.1 Advanced SIMD scalars

Advanced SIMD scalars can be 8-bit, 16-bit, 32-bit, or 64-bit. Instructions other than multiply instructions can access any element in the register set. The instruction syntax refers to the scalars using an index into a doubleword vector. The descriptions of the individual instructions contain details of the encodings.

Table A7-7 shows the form of encoding for scalars used in multiply instructions. These instructions cannot access scalars in some registers. The descriptions of the individual instructions contain cross references to this section where appropriate.

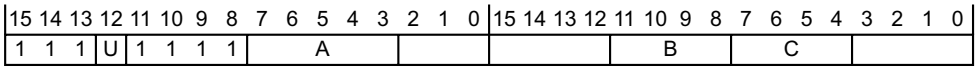
32-bit Advanced SIMD scalars, when used as single-precision floating-point numbers, are equivalent to Floating-point single-precision registers. That is, `Dm[x]` in a 32-bit context (0 <= `m` <= 15, 0 <= `x` <=1) is equivalent to `S[2m + x]`.

Table A7-7 Encoding of scalars in multiply instructions

Scalar mnemonic	Usual usage	Scalar size	Register specifier	Index specifier	Accessible registers
`<Dm[x]>`	Second operand	16-bit	Vm[2:0]	M, Vm[3]	D0-D7
		32-bit	Vm[3:0]	M	D0-D15

A7.4 Advanced SIMD data-processing instructions

The Thumb encoding of Advanced SIMD data processing instructions is:



The ARM encoding of Advanced SIMD data processing instructions is:

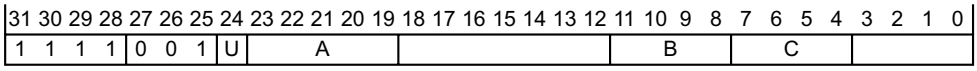


Table A7-8 shows the encoding for Advanced SIMD data-processing instructions. Other encodings in this space are UNDEFINED.

In these instructions, the U bit is in a different location in ARM and Thumb instructions. This is bit[12] of the first halfword in the Thumb encoding, and bit[24] in the ARM encoding. Other variable bits are in identical locations in the two encodings, after adjusting for the fact that the ARM encoding is held in memory as a single word and the Thumb encoding is held as two consecutive halfwords.

The ARM instructions can only be executed unconditionally. The Thumb instructions can be executed conditionally by using the `IT` instruction. For details see *IT* on page A8-390.

	1101	`00000000 abcdefgh 11111111 11111111 00000000 abcdefgh 11111111 11111111`	I32	d, e

Table A7-15 Modified immediate values for Advanced SIMD instructions (continued)

op	cmode	Constant[a]	<dt>[b]	Notes
0	1110	abcdefgh abcdefgh abcdefgh abcdefgh abcdefgh abcdefgh abcdefgh abcdefgh	I8	f
	1111	aBbbbbbc defgh000 00000000 00000000 aBbbbbbc defgh000 00000000 00000000	F32	f, g
1	1110	aaaaaaaa bbbbbbbb cccccccc dddddddd eeeeeeee ffffffff gggggggg hhhhhhhh	I64	f
	1111	UNDEFINED	-	-

a. In this table, the immediate value is shown in binary form, to relate abcdefgh to the encoding diagram. In assembler syntax, the constant is specified by a data type and a value of that type. That value is specified in the normal way (a decimal number by default) and is replicated enough times to fill the 64-bit immediate. For example, a data type of `I32` and a value of 10 specify the 64-bit constant `0x0000000A0000000A`.

b. This specifies the data type used when the instruction is disassembled. On assembly, the data type must be matched in the table if possible. Other data types are permitted as pseudo-instructions when a program is assembled, provided the 64-bit constant specified by the data type and value is available for the instruction. If a constant is available in more than one way, the first entry in this table that can produce it is used. For example, `VMOV.I64 D0, #0x8000000080000000` does not specify a 64-bit constant that is available from the I64 line of the table, but does specify one that is available from the fourth I32 line or the F32 line. It is assembled to the first of these, and therefore is disassembled as `VMOV.I32 D0, #0x80000000`.

c. This constant is available for the `VBIC`, `VMOV`, `VMVN`, and `VORR` instructions.

d. UNPREDICTABLE if `abcdefgh` == 00000000.

e. This constant is available for the `VMOV` and `VMVN` instructions only.

f. This constant is available for the `VMOV` instruction only.

g. In this entry, `B` = NOT(`b`). The bit pattern represents the floating-point number $(-1)^S \times 2^{exp} \times$ mantissa, where S = `UInt(a)`, exp = `UInt(NOT(b):c:d)-3` and mantissa = `(16+UInt(e:f:g:h))/16`.

Advanced SIMD expand immediate pseudocode

```
// AdvSIMDExpandImm()
// ==================

bits(64) AdvSIMDExpandImm(bit op, bits(4) cmode, bits(8) imm8)

    case cmode<3:1> of

            if cmode<0> == '1' && op == '1' then
                UNDEFINED;

    if testimm8 && imm8 == '00000000' then
        UNPREDICTABLE;

    return imm64;
```

A7.5 Floating-point data-processing instructions

The Thumb encoding of Floating-point (VFP) data processing instructions is:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	T	1	1	1	0	opc1				opc2								1	0	1		opc3			0	opc4			

The ARM encoding of Floating-point (VFP) data processing instructions is:

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond				1	1	1	0	opc1				opc2								1	0	1		opc3			0	opc4			

If `T` == 1 in the Thumb encoding or `cond` == `0b1111` in the ARM encoding, the instruction is UNDEFINED.

Otherwise:

- Table A7-16 shows the encodings for three-register Floating-point data-processing instructions. Other encodings in this space are UNDEFINED.
- Table A7-17 applies only if Table A7-16 indicates that it does. It shows the encodings for Floating-point data-processing instructions with two registers or a register and an immediate. Other encodings in this space are UNDEFINED.
- Table A7-18 on page A7-273 shows the immediate constants available in the `VMOV` (immediate) instruction.

These instructions are `CDP` instructions for coprocessors 10 and 11.

a. In this column, B = NOT(b). The bit pattern represents the floating-point number $(-1)^S \times 2^{exp} \times$ mantissa, where S = UInt(a), exp = UInt(NOT(b):c:d)-3 and mantissa = (16+UInt(e:f:g:h))/16.

A7.5.1 Operation of modified immediate constants, Floating-point

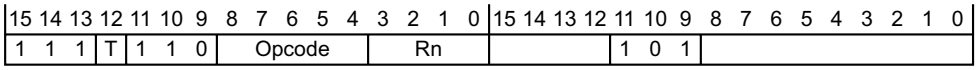
The VFPExpandImm() pseudocode function describes the operation of an immediate constant in a floating-point instruction.

```
// VFPExpandImm()
// ==============

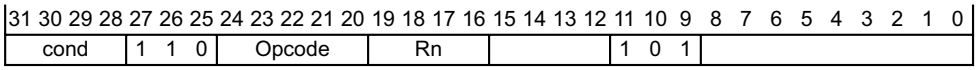
bits(N) VFPExpandImm(bits(8) imm8, integer N)
    assert N IN {32,64};
    if N == 32 then
        return imm8<7>:NOT(imm8<6>):Replicate(imm8<6>,5):imm8<5:0>:Zeros(19);
    else
        return imm8<7>:NOT(imm8<6>):Replicate(imm8<6>,8):imm8<5:0>:Zeros(48);
```

A7.6 Extension register load/store instructions

The Thumb encoding of Advanced SIMD and Floating-point (VFP) Extension register load and store instructions is:



The ARM encoding of Advanced SIMD and Floating-point (VFP) Extension register load and store instructions is:



If `T` == 1 in the Thumb encoding or `cond` == `0b1111` in the ARM encoding, the instruction is UNDEFINED.

Otherwise, the allocation of encodings in this space is shown in Table A7-19. Other encodings in this space are UNDEFINED.

These instructions are `LDC` and `STC` instructions for coprocessors 10 and 11.

Table A7-19 Extension register load/store instructions

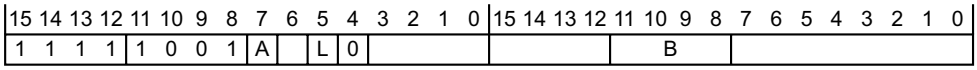
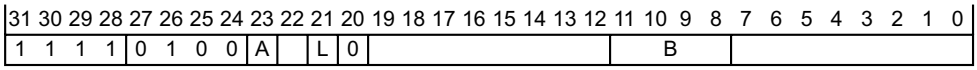
A7.7 Advanced SIMD element or structure load/store instructions

The Thumb encoding of Advanced SIMD element load and store instructions is:



The ARM encoding of Advanced SIMD element load and store instructions is:



The allocation of encodings in this space is shown in:

- Table A7-20 if L == 0. These are the encodings for store instructions.
- Table A7-21 on page A7-276 if L == 1. These are the encodings for load instructions.

Other encodings in this space are UNDEFINED.

The variable bits are in identical locations in the two encodings, after adjusting for the fact that the ARM encoding is held in memory as a single word and the Thumb encoding is held as two consecutive halfwords.

The ARM instructions can only be executed unconditionally. The Thumb instructions can be executed conditionally by using the `IT` instruction. For details see *IT* on page A8-390.

	1111	Vector Load	*VLD4 (single 4-element structure to all lanes)* on page A8-920

A7.7.1 Advanced SIMD addressing mode

All the element and structure load/store instructions use this addressing mode. There is a choice of three formats:

`[<Rn>{:<align>}]`
: The address is contained in ARM core register Rn.

  Rn is not updated by this instruction.

  Encoded as Rm = `0b1111`.

  If Rn is encoded as `0b1111`, the instruction is UNPREDICTABLE.

`[<Rn>{:<align>}]!`
: The address is contained in ARM core register Rn.

  Rn is updated by this instruction: `Rn = Rn + transfer_size`

  Encoded as Rm = `0b1101`.

  `transfer_size` is the number of bytes transferred by the instruction. This means that, after the instruction is executed, Rn points to the address in memory immediately following the last address loaded from or stored to.

  If Rn is encoded as `0b1111`, the instruction is UNPREDICTABLE.

  This addressing mode can also be written as:

  `[<Rn>{:align}], #<transfer_size>`

  However, disassembly produces the `[<Rn>{:align}]!` form.

`[<Rn>{:<align>}], <Rm>`
: The address is contained in ARM core register `<Rn>`.

  Rn is updated by this instruction: `Rn = Rn + Rm`

  Encoded as Rm = Rm. Rm must not be encoded as `0b1111` or `0b1101`, the PC or the SP.

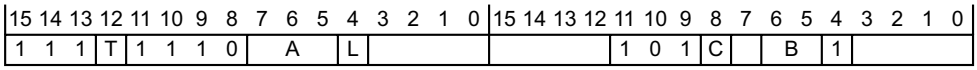
  If Rn is encoded as `0b1111`, the instruction is UNPREDICTABLE.

In all cases, `<align>` specifies an alignment. Details are given in the individual instruction descriptions.

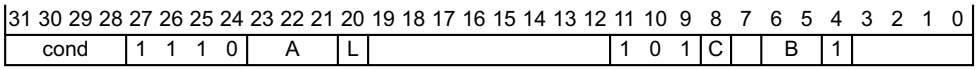
Previous versions of the document used the `@` character for alignment. So, for example, the first format in this section was shown as `[<Rn>{@<align>}]`. Both `@` and `:` are supported. However, to ensure portability of code to assemblers that treat `@` as a comment character, `:` is preferred.

A7.8 8, 16, and 32-bit transfer between ARM core and extension registers

The Thumb encoding of Advanced SIMD and Floating-point 8-bit, 16-bit, and 32-bit register data transfer instructions is:



The ARM encoding of Advanced SIMD and Floating-point 8-bit, 16-bit, and 32-bit register data transfer instructions is:



If `T` == 1 in the Thumb encoding or `cond` == `0b1111` in the ARM encoding, the instruction is UNDEFINED.

Otherwise, the allocation of encodings in this space is shown in Table A7-22. Other encodings in this space are UNDEFINED.

These instructions are `MRC` and `MCR` instructions for coprocessors 10 and 11.

Table A7-22 8-bit, 16-bit and 32-bit data transfer instructions

L	C	A	B	Instruction	See
0	0	000	-	Vector Move	*VMOV (between ARM core register and single-precision register)* on page A8-944

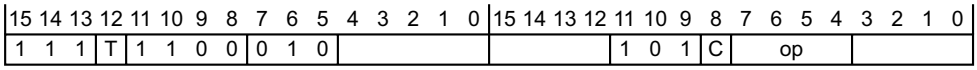
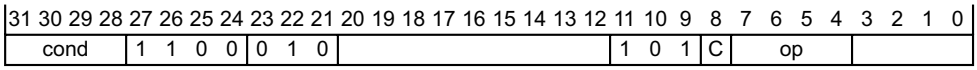
	1	xxx	-	Vector Move	*VMOV (scalar to ARM core register)* on page A8-942

A7.9 64-bit transfers between ARM core and extension registers

The Thumb encoding of Advanced SIMD and Floating-point 64-bit register data transfer instructions is:



The ARM encoding of Advanced SIMD and Floating-point 64-bit register data transfer instructions is:



If `T` == 1 in the Thumb encoding or `cond` == `0b1111` in the ARM encoding, the instruction is UNDEFINED.

Otherwise, the allocation of encodings in this space is shown in Table A7-23. Other encodings in this space are UNDEFINED.

These instructions are `MRRC` and `MCRR` instructions for coprocessors 10 and 11.

Table A7-23 64-bit data transfer instructions

C	op	Instruction
0	00x1	*VMOV (between two ARM core registers and two single-precision registers)* on page A8-946
1	00x1	*VMOV (between two ARM core registers and a doubleword extension register)* on page A8-948

Chapter A8
Instruction Details

This chapter describes each instruction. It contains the following sections:

- *Format of instruction descriptions* on page A8-282
- *Standard assembler syntax fields* on page A8-287
- *Conditional execution* on page A8-288
- *Shifts applied to a register* on page A8-291
- *Memory accesses* on page A8-294
- *Encoding of lists of ARM core registers* on page A8-295
- *Additional pseudocode support for instruction descriptions* on page A8-296
- *Alphabetical list of instructions* on page A8-300.

Note

The *Floating-point Extension* was previously described as the *VFP Extension*, and:

- Different versions of this extension, and the instructions they introduce, are identified using the abbreviation VFP, for example VFPv3.
- The deprecated vector features of the Floating-point Extension are identified as VFP vectors.

A8.1 Format of instruction descriptions

The instruction descriptions in *Alphabetical list of instructions* on page A8-300 normally use the following format:

- instruction section title
- introduction to the instruction
- instruction encoding(s) with architecture information
- assembler syntax
- pseudocode describing how the instruction operates
- exception information
- notes (where applicable).

Each of these items is described in more detail in the following subsections.

A few instruction descriptions describe alternative mnemonics for other instructions and use an abbreviated and modified version of this format.

A8.1.1 Instruction section title

The instruction section title gives the base mnemonic for the instructions described in the section. When one mnemonic has multiple forms described in separate instruction sections, this is followed by a short description of the form in parentheses. The most common use of this is to distinguish between forms of an instruction in which one of the operands is an immediate value and forms in which it is a register.

Another use of parenthesized text is to indicate the former mnemonic in some cases where a mnemonic has been replaced entirely by another mnemonic in the new assembler syntax.

A8.1.2 Introduction to the instruction

The instruction section title is followed by text that briefly describes the main features of the instruction. This description is not necessarily complete and is not definitive. If there is any conflict between it and the more detailed information that follows, the latter takes priority.

A8.1.3 Instruction encodings

This is a list of one or more instruction encodings. Each instruction encoding is labelled as:

- T1, T2, T3 … for the first, second, third and any additional Thumb encodings
- A1, A2, A3 … for the first, second, third and any additional ARM encodings
- E1, E2, E3 … for the first, second, third and any additional ThumbEE encodings that are not also Thumb encodings.

Where Thumb and ARM encodings are very closely related, the two encodings are described together, for example as encoding T1/A1.

Each instruction encoding description consists of:

- Information about which architecture variants include the particular encoding of the instruction. This is presented in one of two ways:
  - For instruction encodings that are in the main instruction set architecture, as a list of the architecture variants that include the encoding. See *Architecture versions, profiles, and variants* on page A1-30 for a summary of these variants.
  - For instruction encodings that are in the architecture extensions, as a list of the architecture extensions that include the encoding. See *Architecture extensions* on page A1-32 for a summary of the architecture extensions and the architecture variants that they can extend.

In architecture variant lists:

— ARMv7 means ARMv7-A and ARMv7-R profiles. The architecture variant information in this manual does not cover the ARMv7-M profile.

— * is used as a wildcard. For example, ARMv5T* means ARMv5T, ARMv5TE, and ARMv5TEJ.

- An assembly syntax that ensures that the assembler selects the encoding in preference to any other encoding. In some cases, multiple syntaxes are given. The correct one to use is sometimes indicated by annotations to the syntax, such as *Inside IT block* and *Outside IT block*. In other cases, the correct one to use can be determined by looking at the assembler syntax description and using it to determine which syntax corresponds to the instruction being disassembled.

  There is usually more than one syntax that ensures re-assembly to any particular encoding, and the exact set of syntaxes that do so usually depends on the register numbers, immediate constants and other operands to the instruction. For example, when assembling to the Thumb instruction set, the syntax `AND R0, R0, R8` ensures selection of a 32-bit encoding but `AND R0, R0, R1` selects a 16-bit encoding.

  The assembly syntax documented for the encoding is chosen to be the simplest one that ensures selection of that encoding for all operand combinations supported by that encoding. This often means that it includes elements that are only necessary for a small subset of operand combinations. For example, the assembler syntax documented for the 32-bit Thumb `AND` (register) encoding includes the `.W` qualifier to ensure that the 32-bit encoding is selected even for the small proportion of operand combinations for which the 16-bit encoding is also available.

  The assembly syntax given for an encoding is therefore a suitable one for a disassembler to disassemble that encoding to. However, disassemblers might wish to use simpler syntaxes when they are suitable for the operand combination, in order to produce more readable disassembled code.

- An encoding diagram, or a Thumb encoding diagram followed by an ARM encoding diagram when they are being described together. This is half-width for 16-bit Thumb encodings and full-width for 32-bit Thumb and ARM encodings. The 32-bit ARM encoding diagrams number the bits from 31 to 0, while the 32-bit Thumb encoding diagrams number the bits from 15 to 0 for each halfword, to distinguish them from ARM encodings and to act as a reminder that a 32-bit Thumb instruction consists of two consecutive halfwords rather than a word.

  In particular, if instructions are stored using the standard little-endian instruction endianness, the encoding diagram for an ARM instruction at address A shows the bytes at addresses A+3, A+2, A+1, A from left to right, but the encoding diagram for a 32-bit Thumb instruction shows them in the order A+1, A for the first halfword, followed by A+3, A+2 for the second halfword.

- Encoding-specific pseudocode. This is pseudocode that translates the encoding-specific instruction fields into inputs to the encoding-independent pseudocode in the later *Operation* subsection, and that picks out any special cases in the encoding. For a detailed description of the pseudocode used and of the relationship between the encoding diagram, the encoding-specific pseudocode and the encoding-independent pseudocode, see Appendix P *Pseudocode Definition*.

A8.1.4 Assembler syntax

The *Assembly syntax* subsection describes the standard UAL syntax for the instruction.

Each syntax description consists of the following elements:

- One or more syntax prototype lines written in a `typewriter` font, using the conventions described in *Assembler syntax prototype line conventions* on page A8-285. Each prototype line documents the mnemonic and (where appropriate) operand parts of a full line of assembler code. When there is more than one such line, each prototype line is annotated to indicate required results of the encoding-specific pseudocode.

For each instruction encoding belonging to a target instruction set, an assembler can use this information to determine whether it can use that encoding to encode the instruction requested by the UAL source. If multiple encodings can encode the instruction then:

— If both a 16-bit encoding and a 32-bit encoding can encode the instruction, the architecture *prefers* the 16-bit encoding. This means the assembler must use the 16-bit encoding rather than the 32-bit encoding.

  Software can use the `.W` and `.N` qualifiers to specify the required encoding width, see *Standard assembler syntax fields* on page A8-287.

— If multiple encodings of the same length can encode the instruction, the *Assembler syntax* subsection says which encoding is preferred, and how software can, instead, select the other encodings.

  Each encoding also documents UAL syntax that selects it in preference to any other encoding.

If no encodings of the target instruction set can encode the instruction requested by the UAL source, normally the assembler generates an error saying that the instruction is not available in that instruction set.

Note

Often, an instruction is available in one instruction set but not in another. The *Assembler syntax* subsection identifies many of these cases. For example, the ARM instructions with bits<31:28> == `0b1111` described in *Unconditional instructions* on page A5-216 cannot have a condition code, but the equivalent Thumb instructions often can, and this usually appears in the *Assembler syntax* subsection as a statement that the ARM instruction cannot be conditional.

However, some such cases are too complex to describe in the available space, so the definitive test of whether an instruction is available in a given instruction set is whether there is an available encoding for it in that instruction set.

- The line *where:* followed by descriptions of all of the variable or optional fields of the prototype syntax line.

  Some syntax fields are standardized across all or most instructions. *Standard assembler syntax fields* on page A8-287 describes these fields.

  By default, syntax fields that specify registers, such as `<Rd>`, `<Rn>`, or `<Rt>`, can be any of R0-R12 or LR in Thumb instructions, and any of R0-R12, SP or LR in ARM instructions. These require that the encoding-specific pseudocode set the corresponding integer variable (such as `d`, `n`, or `t`) to the corresponding register number, using 0-12 for R0-R12, 13 for SP, or 14 for LR:

  — Normally, software can do this by setting the corresponding field in the instruction, typically named Rd, Rn, Rt, to the binary encoding of that number.

  — In the case of 16-bit Thumb encodings, the field is normally of length 3, and so the encoding is only available when the assembler syntax specifies one of R0-R7. Such encodings often use a register field name like Rdn. This indicates that the encoding is only available if `<Rd>` and `<Rn>` specify the same register, and that the register number of that register is encoded in the field if they do.

  The description of a syntax field that specifies a register sometimes extends or restricts the permitted range of registers or documents other differences from the default rules for such fields. Examples of extensions are permitting the use of the SP in a Thumb instruction, or permitting the use of the PC, identified using register number 15.

- Where appropriate, text that briefly describes changes from the pre-UAL ARM assembler syntax. Where present, this usually consists of an alternative pre-UAL form of the assembler mnemonic. The pre-UAL ARM assembler syntax does not conflict with UAL. ARM recommends that it is supported, as an optional extension to UAL, so that pre-UAL ARM assembler source files can be assembled.

Note

The pre-UAL Thumb assembler syntax is incompatible with UAL and is not documented in the instruction sections. For details see Appendix H *Legacy Instruction Mnemonics*.

Assembler syntax prototype line conventions

The following conventions are used in assembler syntax prototype lines and their subfields:

`< >` Any item bracketed by < and > is a short description of a type of value to be supplied by the user in that position. A longer description of the item is normally supplied by subsequent text. Such items often correspond to a similarly named field in an encoding diagram for an instruction. When the correspondence only requires the binary encoding of an integer value or register number to be substituted into the instruction encoding, it is not described explicitly. For example, if the assembler syntax for an ARM instruction contains an item `<Rn>` and the instruction encoding diagram contains a 4-bit field named Rn, the number of the register specified in the assembler syntax is encoded in binary in the instruction field.

If the correspondence between the assembler syntax item and the instruction encoding is more complex than simple binary encoding of an integer or register number, the item description indicates how it is encoded. This is often done by specifying a required output from the encoding-specific pseudocode, such as `add = TRUE`. The assembler must only use encodings that produce that output.

`{ }` Any item bracketed by { and } is optional. A description of the item and of how its presence or absence is encoded in the instruction is normally supplied by subsequent text.

Many instructions have an optional destination register. Unless otherwise stated, if such a destination register is omitted, it is the same as the immediately following source register in the instruction syntax.

`#` In the assembler syntax, numeric constants are normally preceded by a #. Some UAL instruction syntax descriptions explicitly show this # as optional. Any UAL assembler:

- must treat the # as optional where an instruction syntax description shows it as optional
- can treat the # either as mandatory or as optional where an instruction syntax description does not show it as optional.

Note

ARM recommends that UAL assemblers treat all uses of # shown in this manual as optional.

spaces Single spaces are used for clarity, to separate items. When a space is obligatory in the assembler syntax, two or more consecutive spaces are used.

`+/-` This indicates an optional + or - sign. If neither is coded, + is assumed.

All other characters must be encoded precisely as they appear in the assembler syntax. Apart from { and }, the special characters described above do not appear in the basic forms of assembler instructions documented in this manual. The { and } characters need to be encoded in a few places as part of a variable item. When this happens, the long description of the variable item indicates how they must be used.

A8.1.5 Pseudocode describing how the instruction operates

The *Operation* subsection contains encoding-independent pseudocode that describes the main operation of the instruction. For a detailed description of the pseudocode used and of the relationship between the encoding diagram, the encoding-specific pseudocode and the encoding-independent pseudocode, see Appendix P *Pseudocode Definition*.

A8.1.6 Exception information

The *Exceptions* subsection contains a list of the exceptional conditions that can be caused by execution of the instruction.

Processor exceptions are listed as follows:

- Resets and interrupts (both IRQs and FIQs) are not listed. They can occur before or after the execution of any instruction, and in some cases during the execution of an instruction, but they are not in general caused by the instruction concerned.
- Prefetch Abort exceptions are normally caused by a memory abort when an instruction is fetched, followed by an attempt to execute that instruction. This can happen for any instruction, but is caused by the aborted attempt to fetch the instruction rather than by the instruction itself, and so is not listed. A special case is the `BKPT` instruction, that is defined as causing a Prefetch Abort exception in some circumstances.
- Data Abort exceptions are listed for all instructions that perform data memory accesses.
- Undefined Instruction exceptions are listed when they are part of the effects of a defined instruction. For example, all coprocessor instructions are defined to produce the Undefined Instruction exception if not accepted by their coprocessor. Undefined Instruction exceptions caused by the execution of an undefined instruction are not listed, even when the undefined instruction is a special case of one or more of the encodings of the instruction. Such special cases are instead indicated in the encoding-specific pseudocode for the encoding.
- Supervisor Call and Secure Monitor Call exceptions are listed for the `SVC` and `SMC` instructions respectively. Supervisor Call exceptions and the `SVC` instruction were previously called Software Interrupt exceptions and the `SWI` instruction. Secure Monitor Call exceptions and the `SMC` instruction were previously called Secure Monitor interrupts and the `SMI` instruction.

Floating-point exceptions are listed for instructions that can produce them. *Floating-point exceptions* on page A2-70 describes these exceptions. They do not normally result in processor exceptions.

A8.1.7 Notes

Where appropriate, other notes about the instruction appear under additional subheadings.

Note

Information that was documented in notes in previous versions of the ARM Architecture Reference Manual and its supplements has often been moved elsewhere. For example, operand restrictions on the values of fields in an instruction encoding are now normally documented in the encoding-specific pseudocode for that encoding.

A8.2 Standard assembler syntax fields

The following assembler syntax fields are standard across all or most instructions:

<c> Is an optional field. It specifies the condition under which the instruction is executed. See *Conditional execution* on page A8-288 for the range of available conditions and their encoding. If <c> is omitted, it defaults to *always* (AL).

<q> Specifies optional assembler qualifiers on the instruction. The following qualifiers are defined:

- .N Meaning narrow, specifies that the assembler must select a 16-bit encoding for the instruction. If this is not possible, an assembler error is produced.
- .W Meaning wide, specifies that the assembler must select a 32-bit encoding for the instruction. If this is not possible, an assembler error is produced.

If neither .W nor .N is specified, the assembler can select either 16-bit or 32-bit encodings. If both are available, it must select a 16-bit encoding. In a few cases, more than one encoding of the same length can be available for an instruction. The rules for selecting between such encodings are instruction-specific and are part of the instruction description.

Note

When assembling to the ARM instruction set, the .N qualifier produces an assembler error and the .W qualifier has no effect.

A8.3 Conditional execution

Most ARM instructions, and most Thumb instructions from ARMv6T2 onwards, can be executed conditionally, based on the values of the APSR condition flags. Before ARMv6T2, the only conditional Thumb instruction was the 16-bit conditional branch instruction. Table A8-1 lists the available conditions.

Table A8-1 Condition codes

cond	Mnemonic extension	Meaning (integer)	Meaning (floating-point) [a]	Condition flags
0000	EQ	Equal	Equal	Z == 1
0001	NE	Not equal	Not equal, or unordered	Z == 0
0010	CS [b]	Carry set	Greater than, equal, or unordered	C == 1
0011	CC [c]	Carry clear	Less than	C == 0
0100	MI	Minus, negative	Less than	N == 1
0101	PL	Plus, positive or zero	Greater than, equal, or unordered	N == 0
0110	VS	Overflow	Unordered	V == 1
0111	VC	No overflow	Not unordered	V == 0
1000	HI	Unsigned higher	Greater than, or unordered	C == 1 and Z == 0
1001	LS	Unsigned lower or same	Less than or equal	C == 0 or Z == 1
1010	GE	Signed greater than or equal	Greater than or equal	N == V
1011	LT	Signed less than	Less than, or unordered	N != V
1100	GT	Signed greater than	Greater than	Z == 0 and N == V
1101	LE	Signed less than or equal	Less than, equal, or unordered	Z == 1 or N != V
1110	None (AL) [d]	Always (unconditional)	Always (unconditional)	Any

a. Unordered means at least one NaN operand.
b. HS (unsigned higher or same) is a synonym for CS.
c. LO (unsigned lower) is a synonym for CC.
d. AL is an optional mnemonic extension for always, except in IT instructions. For details see *IT* on page A8-390.

In Thumb instructions, the condition, if it is not AL, is normally encoded in a preceding IT instruction. For more information see *Conditional instructions* on page A4-162 and *IT* on page A8-390. Some conditional branch instructions do not require a preceding IT instruction, because they include a condition code in their encoding.

In ARM instructions, bits[31:28] of the instruction contain the condition code, or contain 0b1111 for some ARM instructions that can only be executed unconditionally.

ARM deprecates the conditional execution of any instruction encoding provided by the Advanced SIMD Extension that is not also provided by the Floating-point (VFP) extension, and strongly recommends that:

- For ARM instructions, any such Advanced SIMD instruction that can be conditionally executed is executed with the <c> field omitted or set to AL.

  Note

  This applies only to VDUP, see *VDUP (ARM core register)* on page A8-886. The other instructions do not permit conditional execution in ARM state.

- For Thumb instructions, such Advanced SIMD instructions are never included in an IT block. This means they must be specified with the <c> field omitted or set to AL.

This deprecation does not apply to Advanced SIMD instruction encodings that are also available as Floating-point instruction encodings. That is, it does not apply to the Advanced SIMD encodings of the instructions described in the following sections:

- *VLDM* on page A8-922.
- *VLDR* on page A8-924.
- *VMOV (ARM core register to scalar)* on page A8-940.
- *VMOV (between two ARM core registers and a doubleword extension register)* on page A8-948.
- *VMRS* on page A8-954.
- *VMSR* on page A8-956.
- *VPOP* on page A8-990.
- *VPUSH* on page A8-992.
- *VSTM* on page A8-1080.
- *VSTR* on page A8-1082.

See also *Conditional execution of undefined instructions* on page B1-1208.

A8.3.1 Pseudocode details of conditional execution

The CurrentCond() pseudocode function has prototype:

```
bits(4) CurrentCond()
```

This function returns a 4-bit condition specifier as follows:

- For ARM instructions, it returns bits[31:28] of the instruction.
- For the T1 and T3 encodings of the Branch instruction (see *B* on page A8-334), it returns the 4-bit cond field of the encoding.
- For all other Thumb and ThumbEE instructions:
  - if ITSTATE.IT<3:0> != '0000' it returns ITSTATE.IT<7:4>
  - if ITSTATE.IT<7:0> == '00000000' it returns '1110'
  - otherwise, execution of the instruction is UNPREDICTABLE.

  For more information, see *IT block state register, ITSTATE* on page A2-51.

The ConditionPassed() function uses this condition specifier and the APSR condition flags to determine whether the instruction must be executed:

```
// ConditionPassed()
// =================

boolean ConditionPassed()
    cond = CurrentCond();

    // Evaluate base condition.
    case cond<3:1> of
        when '000'  result = (APSR.Z == '1');                      // EQ or NE
        when '001'  result = (APSR.C == '1');                      // CS or CC
        when '010'  result = (APSR.N == '1');                      // MI or PL
        when '011'  result = (APSR.V == '1');                      // VS or VC
        when '100'  result = (APSR.C == '1') && (APSR.Z == '0');   // HI or LS
        when '101'  result = (APSR.N == APSR.V);                   // GE or LT
        when '110'  result = (APSR.N == APSR.V) && (APSR.Z == '0'); // GT or LE
        when '111'  result = TRUE;                                 // AL

    // Condition flag values in the set '111x' indicate the instruction is always executed.
    // Otherwise, invert condition if necessary.
    if cond<0> == '1' && cond != '1111' then
        result = !result;
```

```
    return result;
```

Undefined Instruction exception on page B1-1205 describes the handling of conditional instructions that are UNDEFINED or UNPREDICTABLE. The pseudocode in the manual, as a sequential description of the instructions, has limitations in this respect. For more information, see *Limitations of the instruction pseudocode* on page AppxP-2644.

A8.4 Shifts applied to a register

ARM register offset load/store word and unsigned byte instructions can apply a wide range of different constant shifts to the offset register. Both Thumb and ARM data-processing instructions can apply the same range of different constant shifts to the second operand register. For details see *Constant shifts*.

ARM data-processing instructions can apply a register-controlled shift to the second operand register.

A8.4.1 Constant shifts

These are the same in Thumb and ARM instructions, except that the input bits come from different positions.

`<shift>` is an optional shift to be applied to `<Rm>`. It can be any one of:

(omitted) No shift.

`LSL #<n>` Logical shift left `<n>` bits. 1 <= `<n>` <= 31.

`LSR #<n>` Logical shift right `<n>` bits. 1 <= `<n>` <= 32.

`ASR #<n>` Arithmetic shift right `<n>` bits. 1 <= `<n>` <= 32.

`ROR #<n>` Rotate right `<n>` bits. 1 <= `<n>` <= 31.

`RRX` Rotate right one bit, with extend. Bit[0] is written to `shifter_carry_out`, bits[31:1] are shifted right one bit, and the Carry flag is shifted into bit[31].

Note

Assemblers can permit the use of some or all of `ASR #0`, `LSL #0`, `LSR #0`, and `ROR #0` to specify that no shift is to be performed. This is not standard UAL, and the encoding selected for Thumb instructions might vary between UAL assemblers if it is used. To ensure disassembled code assembles to the original instructions, disassemblers must omit the shift specifier when the instruction specifies no shift.

Similarly, assemblers can permit the use of `#0` in the immediate forms of `ASR`, `LSL`, `LSR`, and `ROR` instructions to specify that no shift is to be performed, that is, that a `MOV` (register) instruction is wanted. Again, this is not standard UAL, and the encoding selected for Thumb instructions might vary between UAL assemblers if it is used. To ensure disassembled code assembles to the original instructions, disassemblers must use the `MOV` (register) syntax when the instruction specifies no shift.

Encoding

The assembler encodes `<shift>` into two type bits and five immediate bits, as follows:

(omitted) type = `0b00`, immediate = 0.

`LSL #<n>` type = `0b00`, immediate = `<n>`.

`LSR #<n>` type = `0b01`.
If `<n>` < 32, immediate = `<n>`.
If `<n>` == 32, immediate = 0.

`ASR #<n>` type = `0b10`.
If `<n>` < 32, immediate = `<n>`.
If `<n>` == 32, immediate = 0.

`ROR #<n>` type = `0b11`, immediate = `<n>`.

`RRX` type = `0b11`, immediate = 0.

A8.4.2 Register controlled shifts

These are only available in ARM instructions.

<type> is the type of shift to apply to the value read from <Rm>. It must be one of:

ASR	Arithmetic shift right, encoded as type = 0b10.
LSL	Logical shift left, encoded as type = 0b00.
LSR	Logical shift right, encoded as type = 0b01.
ROR	Rotate right, encoded as type = 0b11.

The bottom byte of <Rs> contains the shift amount.

A8.4.3 Pseudocode details of instruction-specified shifts and rotates

```
enumeration SRType {SRType_LSL, SRType_LSR, SRType_ASR, SRType_ROR, SRType_RRX};

// DecodeImmShift()
// ================

(SRType, integer) DecodeImmShift(bits(2) type, bits(5) imm5)

    case type of
        when '00'
            shift_t = SRType_LSL;  shift_n = UInt(imm5);
        when '01'
            shift_t = SRType_LSR;  shift_n = if imm5 == '00000' then 32 else UInt(imm5);
        when '10'
            shift_t = SRType_ASR;  shift_n = if imm5 == '00000' then 32 else UInt(imm5);
        when '11'
            if imm5 == '00000' then
                shift_t = SRType_RRX;  shift_n = 1;
            else
                shift_t = SRType_ROR;  shift_n = UInt(imm5);

    return (shift_t, shift_n);

// DecodeRegShift()
// ================

SRType DecodeRegShift(bits(2) type)
    case type of
        when '00'  shift_t = SRType_LSL;
        when '01'  shift_t = SRType_LSR;
        when '10'  shift_t = SRType_ASR;
        when '11'  shift_t = SRType_ROR;
    return shift_t;

// Shift()
// =======

bits(N) Shift(bits(N) value, SRType type, integer amount, bit carry_in)
    (result, -) = Shift_C(value, type, amount, carry_in);
    return result;

// Shift_C()
// =========

(bits(N), bit) Shift_C(bits(N) value, SRType type, integer amount, bit carry_in)
    assert !(type == SRType_RRX && amount != 1);

    if amount == 0 then
        (result, carry_out) = (value, carry_in);
    else
        case type of
            when SRType_LSL
                (result, carry_out) = LSL_C(value, amount);
```

```
        when SRType_LSR
            (result, carry_out) = LSR_C(value, amount);
        when SRType_ASR
            (result, carry_out) = ASR_C(value, amount);
        when SRType_ROR
            (result, carry_out) = ROR_C(value, amount);
        when SRType_RRX
            (result, carry_out) = RRX_C(value, carry_in);

return (result, carry_out);
```

A8.5 Memory accesses

Commonly, the following addressing modes are permitted for memory access instructions:

Offset addressing

The offset value is applied to an address obtained from the base register. The result is used as the address for the memory access. The value of the base register is unchanged.

The assembly language syntax for this mode is:

`[<Rn>, <offset>]`

Pre-indexed addressing

The offset value is applied to an address obtained from the base register. The result is used as the address for the memory access, and written back into the base register.

The assembly language syntax for this mode is:

`[<Rn>, <offset>]!`

Post-indexed addressing

The address obtained from the base register is used, unchanged, as the address for the memory access. The offset value is applied to the address, and written back into the base register

The assembly language syntax for this mode is:

`[<Rn>], <offset>`

In each case, `<Rn>` is the base register. `<offset>` can be:

- an immediate constant, such as `<imm8>` or `<imm12>`
- an index register, `<Rm>`
- a shifted index register, such as `<Rm>, LSL #<shift>`.

For information about unaligned access, endianness, and exclusive access, see:

- *Alignment support* on page A3-108
- *Endian support* on page A3-110
- *Synchronization and semaphores* on page A3-114.

A8.6 Encoding of lists of ARM core registers

A number of instructions operate on lists of ARM core registers. For these instructions, the assembler syntax includes a <registers> field, that provides a list of the registers to be operated on, with list entries separated by commas.

The registers list is encoded in the instruction encoding. Most often, this is done using an 8-bit, 13-bit, or 16-bit register_list field. This section gives more information about these and other possible register list encodings.

In a register_list field, each bit corresponds to a single register, and if the <registers> field of the assembler instruction includes Rt then register_list<t> is set to 1, otherwise it is set to 0.

The full rules for the encoding of lists of ARM core registers are:

- Except for the cases listed here, 16-bit Thumb encodings use an 8-bit register list, and can access only registers R0-R7.

  The exceptions to this rule are:

  — The T1 encoding of POP uses an 8-bit register list, and an additional bit, P, that corresponds to the PC. This means it can access any of R0-R7 and the PC.

  — The T1 encoding of PUSH uses an 8-bit register list, and an additional bit, M, that corresponds to the LR. This means it can access any of R0-R7 and the LR.

- 32-bit Thumb encodings of load operations use a 13-bit register list, and two additional bits, M, corresponding to the LR, and P, corresponding to the PC. This means these instructions can access any of R0-R12 and the LR and PC.

- 32-bit Thumb encodings of store operations use a 13-bit register list, and one additional bit, M, corresponding to the LR. This means these instructions can access any of R0-R12 and the LR.

- Except for the case listed here, ARM encodings use a 16-bit register list. This means these instructions can access any of R0-R12 and the SP, LR, and PC.

  The exception to this rule is:

  — The system instructions LDM (exception return) and LDM (User registers) use a 15-bit register list. This means these instructions can access any of R0-R12 and the SP and LR.

- The T3 and A2 encodings of POP, and the T3 and A2 encodings of PUSH, access a single register from the set of registers {R0-R12, LR, PC} and encode the register number in the Rt field.

Note

POP is a load operation, and PUSH is a store operation.

In every case, the encoding-specific pseudocode converts the register list into a 32-bit variable, registers, with a bit corresponding to each of the registers R0-R12, SP, LR, and PC.

Note

Some Floating-point and Advanced SIMD instructions operate on lists of Advanced SIMD and Floating-point extension registers. The assembler syntax of these instructions includes a <list> field that specifies the registers to be operated on, and the description of the instruction in *Alphabetical list of instructions* on page A8-300 defines the use and encoding of this field.

A8.7 Additional pseudocode support for instruction descriptions

Earlier sections of this chapter include pseudocode that describes features of the execution of ARM and Thumb instructions, see:

- *Pseudocode details of conditional execution* on page A8-289
- *Pseudocode details of instruction-specified shifts and rotates* on page A8-292

The following subsection gives additional pseudocode support functions for some of the instructions described in *Alphabetical list of instructions* on page A8-300:

A8.7.1 Pseudocode details of coprocessor operations

The `Coproc_Accepted()` pseudocode function determines whether a coprocessor instruction is accepted for execution.

```
// Coproc_Accepted()
// =================
// Determines whether the coprocessor instruction is accepted.

boolean Coproc_Accepted(integer cp_num, bits(32) instr)

    // Not called for CP10 and CP11 coprocessors
    assert !(cp_num IN {10,11});

    if !(cp_num IN {14,15}) then
        // Check against NSACR/CPACR/HCPTR
        if HaveSecurityExt() then
            // Check Non-Secure Access Control Register for permission to use cp_num.
            if !IsSecure() && NSACR<cp_num> == '0' then UNDEFINED;

        // Check Coprocessor Access Control Register for permission to use cp_num.
        if !HaveVirtExt() || !CurrentModeIsHyp() then
            case CPACR<2*cp_num+1:2*cp_num> of
                when '00'  UNDEFINED;
                when '01'  if !CurrentModeIsNotUser() then UNDEFINED;
                           // else CPACR permits access
                when '10'  UNPREDICTABLE;
                when '11'  // CPACR permits access

        if HaveSecurityExt() && HaveVirtExt() && !IsSecure() && HCPTR<cp_num> == '1' then
            HSRString = Zeros(25);
            HSRString<5> = '0';
            HSRString<3:0> = cp_num<3:0>;
            WriteHSR('000111', HSRString);
            if !CurrentModeIsHyp() then
                TakeHypTrapException();
            else
                UNDEFINED;

        return CPxInstrDecode(instr);

    elsif cp_num == 14 then
        // CP14 space
        // Unpack the basic classes based on Opc1
        if instr<27:24> == '1110' && instr<4> == '1' && instr<31:28> != '1111' then
            // MCR/MRC
            opc1 = UInt(instr<23:21>);
            two_reg = FALSE;
        elsif instr<27:20> == '11000100' && instr<31:28> != '1111' then
            // MRRC
            opc1 = UInt(instr<7:4>);
            if opc1 != 0 then UNDEFINED;
            two_reg = TRUE;
        elsif instr<27:25> == '110' && instr<31:28> != '1111' then
            // LDC/STC
            opc1 = 0;                          // only use of LDC/STC is for Debug
```

```
        if UInt(instr<15:12>) != 5 then UNDEFINED;
    else
        UNDEFINED;

    case opc1 of
        // Does not consider possible traps of Debug and Trace registers from
        // Non-secure modes to Hyp mode here.
        when 0  return CP14DebugInstrDecode(instr);
        when 1  return CP14TraceInstrDecode(instr);

        when 6
            // ThumbEE registers - fully decoded here
            if two_reg then UNDEFINED;
            if instr<7:5> != '000' || instr<3:1> != '000' ||
               instr<15:12> == '1111' then
                UNPREDICTABLE;
            else
                if instr<0> == '0' then
                    if !CurrentModeIsNotUser() then UNDEFINED;
                if instr<1> == '1' then
                    if !CurrentModeIsNotUser() && TEECR.XED == '1' then UNDEFINED;

                if HaveSecurityExt() && HaveVirtExt() && !IsSecure() &&
                   !CurrentModeIsHyp() && HSTR.TTEE == '1' then
                    HSRString = Zeros(25);
                    HSRString<19:17> = instr<7:5>;
                    HSRString<16:14> = instr<23:21>;
                    HSRString<13:10> = instr<19:16>;
                    HSRString<8:5> = instr<15:12>;
                    HSRString<4:1> = instr<3:0>;
                    HSRString<0> = instr<20>;
                    WriteHSR('000101', HSRString);
                    TakeHypTrapException();
            return TRUE;

        when 7  return CP14JazelleInstrDecode(instr);
        otherwise
            UNDEFINED;

elsif cp_num == 15 then
    // Only MCR/MCRR/MRRC/MRC are supported in CP15
    if instr<27:24> == '1110' && instr<4> == '1' && instr<31:28> != '1111' then

            HSRString<0> = instr<20>;
            WriteHSR('000100', HSRString);
```

```
            else
                HSRString<19:17> = instr<7:5>;
                HSRString<16:14> = instr<23:21>;
                HSRString<13:10> = instr<19:16>;
                HSRString<8:5> = instr<15:12>;
                HSRString<4:1> = instr<3:0>;
                HSRString<0> = instr<20>;
                WriteHSR('000011', HSRString);
            TakeHypTrapException();

        // Check for TIDCP as a coarse-grain check for PL1 accesses
        if HaveSecurityExt() && HaveVirtExt() && !IsSecure() && !CurrentModeIsHyp() &&
           HCR.TIDCP == '1' && !two_reg then
            CrMnum = UInt(instr<3:0>);
            if (CrNnum == 9 && CrMnum IN {0,2,5,6,7,8}) ||
               (CrNnum == 10 && CrMnum IN {0,1,4,8}) ||
               (CrNnum == 11 && CrMnum IN {0,1,2,3,4,5,6,7,8,15}) then
                if !CurrentModeIsNotUser() && InstrIsPL0Undefined(instr) then
                    IMPLEMENTATION_CHOICE to be UNDEFINED;
                HSRString = Zeros(25);
                HSRString<19:17> = instr<7:5>;
                HSRString<16:14> = instr<23:21>;
                HSRString<13:10> = instr<19:16>;
                HSRString<8:5> = instr<15:12>;
                HSRString<4:1> = instr<3:0>;
                HSRString<0> = instr<20>;
                WriteHSR('000011', HSRString);
                TakeHypTrapException();

        return CP15InstrDecode(instr);
```

The `Coproc_DoneLoading()` pseudocode function determines, for an `LDC` instruction, whether enough words have been loaded:

```
boolean Coproc_DoneLoading(integer cp_num, bits(32) instr)
```

The `Coproc_DoneStoring()` function determines for an `STC` instruction whether enough words have been stored:

```
boolean Coproc_DoneStoring(integer cp_num, bits(32) instr)
```

The `Coproc_GetOneWord()` function obtains the word for an `MRC` instruction from the coprocessor:

```
bits(32) Coproc_GetOneWord(integer cp_num, bits(32) instr)
```

The `Coproc_GetTwoWords()` function obtains the two words for an `MRRC` instruction from the coprocessor:

```
(bits(32), bits(32)) Coproc_GetTwoWords(integer cp_num, bits(32) instr)
```

Note

The relative significance of the two words returned is IMPLEMENTATION DEFINED, but all uses within this manual present the two words in the order (most significant, least significant).

The `Coproc_GetWordToStore()` function obtains the next word to store for an `STC` instruction from the coprocessor:

```
bits(32) Coproc_GetWordToStore(integer cp_num, bits(32) instr)
```

The `Coproc_InternalOperation()` procedure instructs a coprocessor to perform the internal operation requested by a `CDP` instruction:

```
Coproc_InternalOperation(integer cp_num, bits(32) instr)
```

The `Coproc_SendLoadedWord()` procedure sends a loaded word for an `LDC` instruction to the coprocessor:

```
Coproc_SendLoadedWord(bits(32) word, integer cp_num, bits(32) instr)
```

The `Coproc_SendOneWord()` procedure sends the word for an `MCR` instruction to the coprocessor:

```
Coproc_SendOneWord(bits(32) word, integer cp_num, bits(32) instr)
```

The Coproc_SendTwoWords() procedure sends the two words for an MCRR instruction to the coprocessor:

```
Coproc_SendTwoWords(bits(32) word2, bits(32) word1, integer cp_num, bits(32) instr)
```

Note

The relative significance of word2 and word1 is IMPLEMENTATION DEFINED, but all uses within this manual treat word2 as more significant than word1.

The CPxInstrDecode() pseudocode function decodes an accepted access to a coprocessor other than CP10, CP11, CP14, or CP15:

```
boolean CPxInstrDecode(bits(32) instr)
```

The CP14DebugInstrDecode() pseudocode function decodes an accepted access to a CP14 debug register:

```
boolean CP14DebugInstrDecode(bits(32) instr)
```

The CP14JazelleInstrDecode() pseudocode function decodes an accepted access to a CP14 Jazelle register:

```
boolean CP14JazelleInstrDecode(bits(32) instr)
```

The CP14TraceInstrDecode() pseudocode function decodes an accepted access to a CP14 Trace register:

```
boolean CP14TraceInstrDecode(bits(32) instr)
```

The CP15InstrDecode() pseudocode function decodes an accepted access to a CP15 register:

```
boolean CP15InstrDecode(bits(32) instr)
```

A8.7.2 Calling the supervisor

The CallSupervisor() pseudocode function generates a Supervisor Call exception, after setting up the HSR if the exception must be taken to Hyp mode. Valid execution of the SVC instruction calls this function.

```
// CallSupervisor()
// ================
//
// Calls the Supervisor, with appropriate trapping etc

CallSupervisor(bits(16) immediate)

    if CurrentModeIsHyp() ||
       (HaveVirtExt() && !IsSecure() && !CurrentModeIsNotUser() && HCR.TGE == '1') then
        // will be taken to Hyp mode so must set HSR
        HSRString = Zeros(25);
        HSRString<15:0> = if CurrentCond() == '1110' then immediate else bits(16) UNKNOWN;
        WriteHSR('010001', HSRString);

    // This will go to Hyp mode if necessary
    TakeSVCException();
```

A8.8 Alphabetical list of instructions

This section lists every instruction. For details of the format used see *Format of instruction descriptions* on page A8-282.

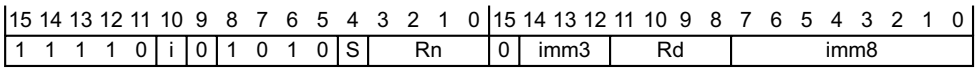
This section is formatted so that a full description of an instruction uses a double page.

A8.8.1 ADC (immediate)

Add with Carry (immediate) adds an immediate value and the Carry flag value to a register value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

Encoding T1 ARMv6T2, ARMv7

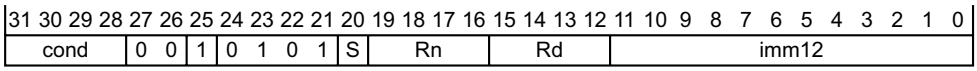
```
ADC{S}<c> <Rd>, <Rn>, #<const>
```



```
d = UInt(Rd);  n = UInt(Rn);  setflags = (S == '1');  imm32 = ThumbExpandImm(i:imm3:imm8);
if d IN {13,15} || n IN {13,15} then UNPREDICTABLE;
```

Encoding A1 ARMv4*, ARMv5T*, ARMv6*, ARMv7

```
ADC{S}<c> <Rd>, <Rn>, #<const>
```



```
if Rd == '1111' && S == '1' then SEE SUBS PC, LR and related instructions;
d = UInt(Rd);  n = UInt(Rn);  setflags = (S == '1');  imm32 = ARMExpandImm(imm12);
```

Assembler syntax

```
ADC{S}{<c>}{<q>}  {<Rd>,} <Rn>, #<const>
```

where:

S — If S is present, the instruction updates the flags. Otherwise, the flags are not updated.

<c>, <q> — See *Standard assembler syntax fields* on page A8-287.

<Rd> — The destination register. If S is specified and <Rd> is the PC, see *SUBS PC, LR (Thumb)* on page B9-2008 or *SUBS PC, LR and related instructions (ARM)* on page B9-2010.

In ARM instructions, if S is not specified and <Rd> is the PC, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode details of operations on ARM core registers* on page A2-47.

Note

Before ARMv7, this was a simple branch.

<Rn> — The first operand register. The PC can be used in ARM instructions.

<const> — The immediate value to be added to the value obtained from <Rn>. See *Modified immediate constants in Thumb instructions* on page A6-232 or *Modified immediate constants in ARM instructions* on page A5-200 for the range of values.

The pre-UAL syntax ADC<c>S is equivalent to ADCS<c>.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    (result, carry, overflow) = AddWithCarry(R[n], imm32, APSR.C);
    if d == 15 then          // Can only occur for ARM encoding
        ALUWritePC(result);  // setflags is always FALSE here
    else
        R[d] = result;
        if setflags then
            APSR.N = result<31>;
            APSR.Z = IsZeroBit(result);
            APSR.C = carry;
            APSR.V = overflow;
```

Exceptions

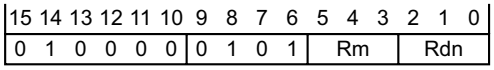
None.

A8.8.2 ADC (register)

Add with Carry (register) adds a register value, the Carry flag value, and an optionally-shifted register value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

Encoding T1 ARMv4T, ARMv5T*, ARMv6*, ARMv7

```
ADCS <Rdn>, <Rm>                    Outside IT block.
ADC<c> <Rdn>, <Rm>                  Inside IT block.
```

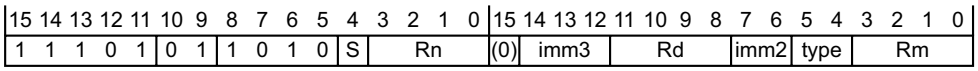


15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	0	0	0	0	0	1	0	1	Rm			Rdn		

```
d = UInt(Rdn);  n = UInt(Rdn);  m = UInt(Rm);  setflags = !InITBlock();
(shift_t, shift_n) = (SRType_LSL, 0);
```

Encoding T2 ARMv6T2, ARMv7

```
ADC{S}<c>.W <Rd>, <Rn>, <Rm>{, <shift>}
```

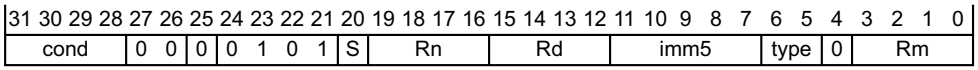


15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	0	1	0	1	1	0	1	0	S	Rn				(0)	imm3			Rd				imm2		type		Rm			

```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  setflags = (S == '1');
(shift_t, shift_n) = DecodeImmShift(type, imm3:imm2);
if d IN {13,15} || n IN {13,15} || m IN {13,15} then UNPREDICTABLE;
```

Encoding A1 ARMv4*, ARMv5T*, ARMv6*, ARMv7

```
ADC{S}<c> <Rd>, <Rn>, <Rm>{, <shift>}
```



31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond				0	0	0	0	1	0	1	S	Rn				Rd				imm5					type		0	Rm				

```
if Rd == '1111' && S == '1' then SEE SUBS PC, LR and related instructions;
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  setflags = (S == '1');
(shift_t, shift_n) = DecodeImmShift(type, imm5);
```

Assembler syntax

```
ADC{S}{<c>}{<q>}  {<Rd>,} <Rn>, <Rm> {, <shift>}
```

where:

S	If S is present, the instruction updates the flags. Otherwise, the flags are not updated.
<c>, <q>	See *Standard assembler syntax fields* on page A8-287.
<Rd>	The destination register. If S is specified and <Rd> is the PC, see *SUBS PC, LR (Thumb)* on page B9-2008 or *SUBS PC, LR and related instructions (ARM)* on page B9-2010. In ARM instructions, if S is not specified and <Rd> is the PC, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode details of operations on ARM core registers* on page A2-47. **Note** Before ARMv7, this was a simple branch.
<Rn>	The first operand register. The PC can be used in ARM instructions.
<Rm>	The optionally shifted second operand register. The PC can be used in ARM instructions.
<shift>	The shift to apply to the value read from <Rm>. If present, encoding T1 is not permitted. If absent, no shift is applied and any encoding is permitted. *Shifts applied to a register* on page A8-291 describes the shifts and how they are encoded.

In Thumb assembly:

- outside an IT block, if `ADCS <Rd>, <Rn>, <Rd>` has <Rd> and <Rn> both in the range R0-R7, it is assembled using encoding T1 as though `ADCS <Rd>, <Rn>` had been written.
- inside an IT block, if `ADC<c> <Rd>, <Rn>, <Rd>` has <Rd> and <Rn> both in the range R0-R7, it is assembled using encoding T1 as though `ADC<c> <Rd>, <Rn>` had been written.

To prevent either of these happening, use the .W qualifier.

The pre-UAL syntax `ADC<c>S` is equivalent to `ADCS<c>`.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shifted = Shift(R[m], shift_t, shift_n, APSR.C);
    (result, carry, overflow) = AddWithCarry(R[n], shifted, APSR.C);
    if d == 15 then          // Can only occur for ARM encoding
        ALUWritePC(result);  // setflags is always FALSE here
    else
        R[d] = result;
        if setflags then
            APSR.N = result<31>;
            APSR.Z = IsZeroBit(result);
            APSR.C = carry;
            APSR.V = overflow;
```

Exceptions

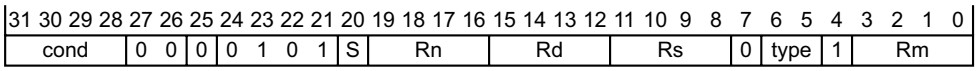
None.

A8.8.3 ADC (register-shifted register)

Add with Carry (register-shifted register) adds a register value, the Carry flag value, and a register-shifted register value. It writes the result to the destination register, and can optionally update the condition flags based on the result.

Encoding A1 ARMv4*, ARMv5T*, ARMv6*, ARMv7

```
ADC{S}<c> <Rd>, <Rn>, <Rm>, <type> <Rs>
```



31 30 29 28	27 26 25	24 23 22 21	20	19 18 17 16	15 14 13 12	11 10 9 8	7	6 5	4	3 2 1 0
cond	0 0 0	0 1 0 1	S	Rn	Rd	Rs	0	type	1	Rm

```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  s = UInt(Rs);
setflags = (S == '1');  shift_t = DecodeRegShift(type);
if d == 15 || n == 15 || m == 15 || s == 15 then UNPREDICTABLE;
```

Assembler syntax

```
ADC{S}{<c>}{<q>}  {<Rd>,} <Rn>, <Rm>, <type>  <Rs>
```

where:

S — If S is present, the instruction updates the flags. Otherwise, the flags are not updated.

<c>, <q> — See *Standard assembler syntax fields* on page A8-287.

<Rd> — The destination register.

<Rn> — The first operand register.

<Rm> — The register that is shifted and used as the second operand.

<type> — The type of shift to apply to the value read from <Rm>. It must be one of:

- ASR — Arithmetic shift right, encoded as type = 0b10.
- LSL — Logical shift left, encoded as type = 0b00.
- LSR — Logical shift right, encoded as type = 0b01.
- ROR — Rotate right, encoded as type = 0b11.

<Rs> — The register whose bottom byte contains the amount to shift by.

The pre-UAL syntax ADC<c>S is equivalent to ADCS<c>.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shift_n = UInt(R[s]<7:0>);
    shifted = Shift(R[m], shift_t, shift_n, APSR.C);
    (result, carry, overflow) = AddWithCarry(R[n], shifted, APSR.C);
    R[d] = result;
    if setflags then
        APSR.N = result<31>;
        APSR.Z = IsZeroBit(result);
        APSR.C = carry;
        APSR.V = overflow;
```

Exceptions

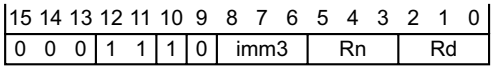
None.

A8.8.4 ADD (immediate, Thumb)

This instruction adds an immediate value to a register value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

Encoding T1 ARMv4T, ARMv5T*, ARMv6*, ARMv7

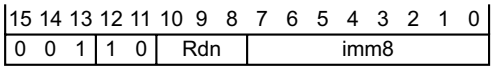
```
ADDS <Rd>, <Rn>, #<imm3>                    Outside IT block.
ADD<c> <Rd>, <Rn>, #<imm3>                  Inside IT block.
```



```
d = UInt(Rd);  n = UInt(Rn);  setflags = !InITBlock();  imm32 = ZeroExtend(imm3, 32);
```

Encoding T2 ARMv4T, ARMv5T*, ARMv6*, ARMv7

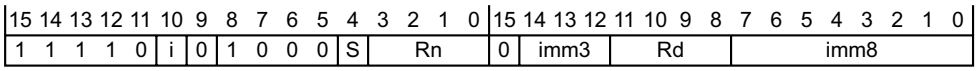
```
ADDS <Rdn>, #<imm8>                         Outside IT block.
ADD<c> <Rdn>, #<imm8>                       Inside IT block.
```



```
d = UInt(Rdn);  n = UInt(Rdn);  setflags = !InITBlock();  imm32 = ZeroExtend(imm8, 32);
```

Encoding T3 ARMv6T2, ARMv7

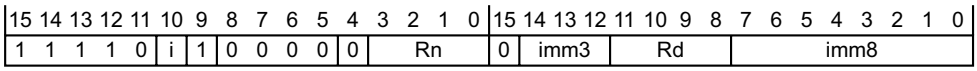
```
ADD{S}<c>.W <Rd>, <Rn>, #<const>
```



```
if Rd == '1111' && S == '1' then SEE CMN (immediate);
if Rn == '1101' then SEE ADD (SP plus immediate);
d = UInt(Rd);  n = UInt(Rn);  setflags = (S == '1');  imm32 = ThumbExpandImm(i:imm3:imm8);
if d == 13 || (d == 15 && S == '0') || n == 15 then UNPREDICTABLE;
```

Encoding T4 ARMv6T2, ARMv7

```
ADDW<c> <Rd>, <Rn>, #<imm12>
```



```
if Rn == '1111' then SEE ADR;
if Rn == '1101' then SEE ADD (SP plus immediate);
d = UInt(Rd);  n = UInt(Rn);  setflags = FALSE;  imm32 = ZeroExtend(i:imm3:imm8, 32);
if d IN {13,15} then UNPREDICTABLE;
```

Assembler syntax

`ADD{S}{<c>}{<q>}  {<Rd>,} <Rn>, #<const>`	All encodings permitted
`ADDW{<c>}{<q>}  {<Rd>,} <Rn>, #<const>`	Only encoding T4 permitted

where:

`S` If `S` is present, the instruction updates the flags. Otherwise, the flags are not updated.

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287.

`<Rd>` The destination register.

`<Rn>` The first operand register. If `<Rn>` is SP, see *ADD (SP plus immediate)* on page A8-316. If `<Rn>` is PC, see *ADR* on page A8-322.

`<const>` The immediate value to be added to the value obtained from `<Rn>`. The range of values is 0-7 for encoding T1, 0-255 for encoding T2 and 0-4095 for encoding T4. See *Modified immediate constants in Thumb instructions* on page A6-232 for the range of values for encoding T3.

When multiple encodings of the same length are available for an instruction, encoding T3 is preferred to encoding T4 (if encoding T4 is required, use the `ADDW` syntax). Encoding T1 is preferred to encoding T2 if `<Rd>` is specified and encoding T2 is preferred to encoding T1 if `<Rd>` is omitted.

The pre-UAL syntax `ADD<c>S` is equivalent to `ADDS<c>`.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    (result, carry, overflow) = AddWithCarry(R[n], imm32, '0');
    R[d] = result;
    if setflags then
        APSR.N = result<31>;
        APSR.Z = IsZeroBit(result);
        APSR.C = carry;
        APSR.V = overflow;
```

Exceptions

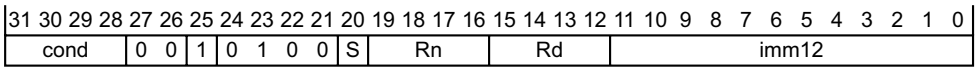
None.

A8.8.5 ADD (immediate, ARM)

This instruction adds an immediate value to a register value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

Encoding A1 ARMv4*, ARMv5T*, ARMv6*, ARMv7

```
ADD{S}<c> <Rd>, <Rn>, #<const>
```



```
if Rn == '1111' && S == '0' then SEE ADR;
if Rn == '1101' then SEE ADD (SP plus immediate);
if Rd == '1111' && S == '1' then SEE SUBS PC, LR and related instructions;
d = UInt(Rd);  n = UInt(Rn);  setflags = (S == '1');  imm32 = ARMExpandImm(imm12);
```

Assembler syntax

```
ADD{S}{<c>}{<q>}  {<Rd>,} <Rn>, #<const>
```

where:

S — If S is present, the instruction updates the flags. Otherwise, the flags are not updated.

<c>, <q> — See *Standard assembler syntax fields* on page A8-287.

<Rd> — The destination register. If S is specified and <Rd> is the PC, see *SUBS PC, LR (Thumb)* on page B9-2008 or *SUBS PC, LR and related instructions (ARM)* on page B9-2010.

If S is not specified and <Rd> is the PC, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode details of operations on ARM core registers* on page A2-47.

Note

Before ARMv7, this was a simple branch.

<Rn> — The first operand register. If the SP is specified for <Rn>, see *ADD (SP plus immediate)* on page A8-316. If the PC is specified for <Rn>, see *ADR* on page A8-322.

<const> — The immediate value to be added to the value obtained from <Rn>. See *Modified immediate constants in ARM instructions* on page A5-200 for the range of values.

The pre-UAL syntax ADD<c>S is equivalent to ADDS<c>.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    (result, carry, overflow) = AddWithCarry(R[n], imm32, '0');
    if d == 15 then
        ALUWritePC(result);  // setflags is always FALSE here
    else
        R[d] = result;
        if setflags then
            APSR.N = result<31>;
            APSR.Z = IsZeroBit(result);
            APSR.C = carry;
            APSR.V = overflow;
```

Exceptions

None.

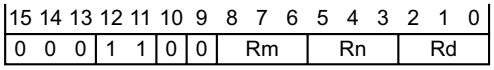
A8.8.6 ADD (register, Thumb)

This instruction adds a register value and an optionally-shifted register value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

Encoding T1 ARMv4T, ARMv5T*, ARMv6*, ARMv7

`ADDS <Rd>, <Rn>, <Rm>` Outside IT block.

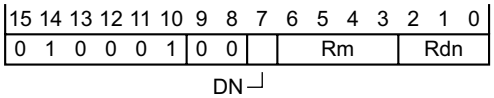
`ADD<c> <Rd>, <Rn>, <Rm>` Inside IT block.



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  setflags = !InITBlock();
(shift_t, shift_n) = (SRType_LSL, 0);
```

Encoding T2 ARMv6T2, ARMv7 if <Rdn> and <Rm> are both from R0-R7
ARMv4T, ARMv5T*, ARMv6*, ARMv7 otherwise

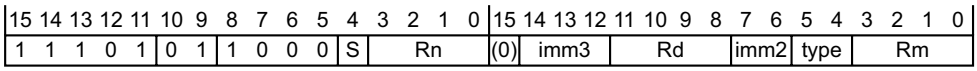
`ADD<c> <Rdn>, <Rm>` If <Rdn> is the PC, must be outside or last in IT block.



```
if (DN:Rdn) == '1101' || Rm == '1101' then SEE ADD (SP plus register);
d = UInt(DN:Rdn);  n = d;  m = UInt(Rm);  setflags = FALSE;  (shift_t, shift_n) = (SRType_LSL, 0);
if n == 15 && m == 15 then UNPREDICTABLE;
if d == 15 && InITBlock() && !LastInITBlock() then UNPREDICTABLE;
```

Encoding T3 ARMv6T2, ARMv7

`ADD{S}<c>.W <Rd>, <Rn>, <Rm>{, <shift>}`



```
if Rd == '1111' && S == '1' then SEE CMN (register);
if Rn == '1101' then SEE ADD (SP plus register);
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  setflags = (S == '1');
(shift_t, shift_n) = DecodeImmShift(type, imm3:imm2);
if d == 13 || (d == 15 && S == '0') || n == 15 || m IN {13,15} then UNPREDICTABLE;
```

Assembler syntax

```
ADD{S}{<c>}{<q>}  {<Rd>,} <Rn>, <Rm> {, <shift>}
```

where:

`S`	If `S` is present, the instruction updates the flags. Otherwise, the flags are not updated.
`<c>, <q>`	See *Standard assembler syntax fields* on page A8-287.
`<Rd>`	The destination register. If `S` is specified and `<Rd>` is the PC, see *CMN (register)* on page A8-366. If omitted, `<Rd>` is the same as `<Rn>` and encoding T2 is preferred to encoding T1 inside an IT block. If `<Rd>` is present, encoding T1 is preferred to encoding T2. If `<Rd>` is the PC and `S` is not specified, encoding T2 is used and the instruction is a branch to the address calculated by the operation. This is a simple branch, see *Pseudocode details of operations on ARM core registers* on page A2-47.
`<Rn>`	The first operand register. The PC can be used in encoding T2. If `<Rn>` is SP, see *ADD (SP plus register, Thumb)* on page A8-318.
`<Rm>`	The register that is optionally shifted and used as the second operand. The PC can be used in encoding T2
`<shift>`	The shift to apply to the value read from `<Rm>`. If present, only encoding T3 is permitted. If omitted, no shift is applied and any encoding is permitted. *Shifts applied to a register* on page A8-291 describes the shifts and how they are encoded.

Inside an IT block, if `ADD<c> <Rd>, <Rn>, <Rd>` cannot be assembled using encoding T1, it is assembled using encoding T2 as though `ADD<c> <Rd>, <Rn>` had been written. To prevent this happening, use the `.W` qualifier.

The pre-UAL syntax `ADD<c>S` is equivalent to `ADDS<c>`.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shifted = Shift(R[m], shift_t, shift_n, APSR.C);
    (result, carry, overflow) = AddWithCarry(R[n], shifted, '0');
    if d == 15 then
        ALUWritePC(result);  // setflags is always FALSE here
    else
        R[d] = result;
        if setflags then
            APSR.N = result<31>;
            APSR.Z = IsZeroBit(result);
            APSR.C = carry;
            APSR.V = overflow;
```

Exceptions

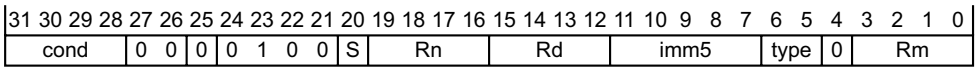
None.

A8.8.7 ADD (register, ARM)

This instruction adds a register value and an optionally-shifted register value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

Encoding A1 ARMv4*, ARMv5T*, ARMv6*, ARMv7

```
ADD{S}<c> <Rd>, <Rn>, <Rm>{, <shift>}
```



31 30 29 28	27 26 25	24 23 22 21	20	19 18 17 16	15 14 13 12	11 10 9 8 7	6 5	4	3 2 1 0
cond	0 0 0	0 1 0 0	S	Rn	Rd	imm5	type	0	Rm

```
if Rd == '1111' && S == '1' then SEE SUBS PC, LR and related instructions;
if Rn == '1101' then SEE ADD (SP plus register);
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  setflags = (S == '1');
(shift_t, shift_n) = DecodeImmShift(type, imm5);
```

Assembler syntax

```
ADD{S}{<c>}{<q>}  {<Rd>,} <Rn>, <Rm> {, <shift>}
```

where:

S — If S is present, the instruction updates the flags. Otherwise, the flags are not updated.

<c>, <q> — See *Standard assembler syntax fields* on page A8-287.

<Rd> — The destination register. If S is specified and <Rd> is the PC, see *SUBS PC, LR and related instructions (ARM)* on page B9-2010. If omitted, <Rd> is the same as <Rn>.

If <Rd> is the PC and S is not specified, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode details of operations on ARM core registers* on page A2-47.

Note

Before ARMv7, this was a simple branch.

<Rn> — The first operand register. The PC can be used. If <Rn> is SP, see *ADD (SP plus register, Thumb)* on page A8-318.

<Rm> — The register that is optionally shifted and used as the second operand. The PC can be used.

<shift> — The shift to apply to the value read from <Rm>. If present, only encoding T3 or A1 is permitted. If omitted, no shift is applied and any encoding is permitted. *Shifts applied to a register* on page A8-291 describes the shifts and how they are encoded.

The pre-UAL syntax ADD<c>S is equivalent to ADDS<c>.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shifted = Shift(R[m], shift_t, shift_n, APSR.C);
    (result, carry, overflow) = AddWithCarry(R[n], shifted, '0');
    if d == 15 then
        ALUWritePC(result);  // setflags is always FALSE here
    else
        R[d] = result;
        if setflags then
            APSR.N = result<31>;
            APSR.Z = IsZeroBit(result);
            APSR.C = carry;
            APSR.V = overflow;
```

Exceptions

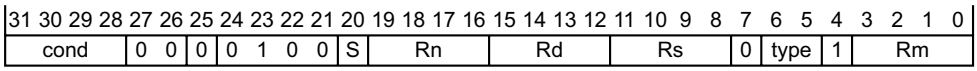
None.

A8.8.8 ADD (register-shifted register)

Add (register-shifted register) adds a register value and a register-shifted register value. It writes the result to the destination register, and can optionally update the condition flags based on the result.

Encoding A1 ARMv4*, ARMv5T*, ARMv6*, ARMv7

```
ADD{S}<c> <Rd>, <Rn>, <Rm>, <type> <Rs>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  s = UInt(Rs);
setflags = (S == '1');  shift_t = DecodeRegShift(type);
if d == 15 || n == 15 || m == 15 || s == 15 then UNPREDICTABLE;
```

Assembler syntax

```
ADD{S}{<c>}{<q>}  {<Rd>,} <Rn>, <Rm>, <type>  <Rs>
```

where:

S — If S is present, the instruction updates the flags. Otherwise, the flags are not updated.

<c>, <q> — See *Standard assembler syntax fields* on page A8-287.

<Rd> — The destination register.

<Rn> — The first operand register.

<Rm> — The register that is shifted and used as the second operand.

<type> — The type of shift to apply to the value read from <Rm>. It must be one of:

- ASR — Arithmetic shift right, encoded as type = 0b10.
- LSL — Logical shift left, encoded as type = 0b00.
- LSR — Logical shift right, encoded as type = 0b01.
- ROR — Rotate right, encoded as type = 0b11.

<Rs> — The register whose bottom byte contains the amount to shift by.

The pre-UAL syntax ADD<c>S is equivalent to ADDS<c>.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shift_n = UInt(R[s]<7:0>);
    shifted = Shift(R[m], shift_t, shift_n, APSR.C);
    (result, carry, overflow) = AddWithCarry(R[n], shifted, '0');
    R[d] = result;
    if setflags then
        APSR.N = result<31>;
        APSR.Z = IsZeroBit(result);
        APSR.C = carry;
        APSR.V = overflow;
```

Exceptions

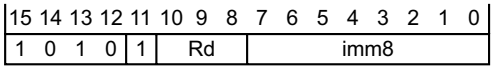
None.

A8.8.9 ADD (SP plus immediate)

This instruction adds an immediate value to the SP value, and writes the result to the destination register.

Encoding T1 ARMv4T, ARMv5T*, ARMv6*, ARMv7

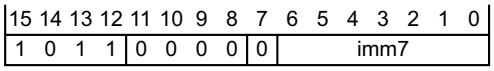
```
ADD<c> <Rd>, SP, #<imm>
```



```
d = UInt(Rd);  setflags = FALSE;  imm32 = ZeroExtend(imm8:'00', 32);
```

Encoding T2 ARMv4T, ARMv5T*, ARMv6*, ARMv7

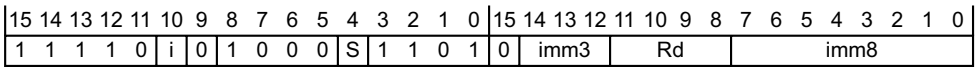
```
ADD<c> SP, SP, #<imm>
```



```
d = 13;  setflags = FALSE;  imm32 = ZeroExtend(imm7:'00', 32);
```

Encoding T3 ARMv6T2, ARMv7

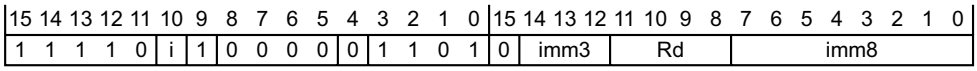
```
ADD{S}<c>.W <Rd>, SP, #<const>
```



```
if Rd == '1111' && S == '1' then SEE CMN (immediate);
d = UInt(Rd);  setflags = (S == '1');  imm32 = ThumbExpandImm(i:imm3:imm8);
if d == 15 && S == '0' then UNPREDICTABLE;
```

Encoding T4 ARMv6T2, ARMv7

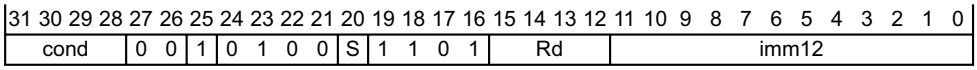
```
ADDW<c> <Rd>, SP, #<imm12>
```



```
d = UInt(Rd);  setflags = FALSE;  imm32 = ZeroExtend(i:imm3:imm8, 32);
if d == 15 then UNPREDICTABLE;
```

Encoding A1 ARMv4*, ARMv5T*, ARMv6*, ARMv7

```
ADD{S}<c> <Rd>, SP, #<const>
```



```
if Rd == '1111' && S == '1' then SEE SUBS PC, LR and related instructions;
d = UInt(Rd);  setflags = (S == '1');  imm32 = ARMExpandImm(imm12);
```

Assembler syntax

`ADD{S}{<c>}{<q>}  {<Rd>,} SP, #<const>`	All encodings permitted
`ADDW{<c>}{<q>}  {<Rd>,} SP, #<const>`	Only encoding T4 is permitted

where:

`S` If `S` is present, the instruction updates the flags. Otherwise, the flags are not updated.

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287.

`<Rd>` The destination register. If `S` is specified and `<Rd>` is the PC, see *SUBS PC, LR (Thumb)* on page B9-2008 or *SUBS PC, LR and related instructions (ARM)* on page B9-2010. If omitted, `<Rd>` is SP.

In ARM instructions, if `S` is not specified and `<Rd>` is the PC, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode details of operations on ARM core registers* on page A2-47.

Note

Before ARMv7, this was a simple branch.

`<const>` The immediate value to be added to the value obtained from SP. Values are multiples of 4 in the range 0-1020 for encoding T1, multiples of 4 in the range 0-508 for encoding T2 and any value in the range 0-4095 for encoding T4. See *Modified immediate constants in Thumb instructions* on page A6-232 or *Modified immediate constants in ARM instructions* on page A5-200 for the range of values for encodings T3 and A1.

When both 32-bit encodings are available for an instruction, encoding T3 is preferred to encoding T4.

Note

If encoding T4 is required, use the `ADDW` syntax.

The pre-UAL syntax `ADD<c>S` is equivalent to `ADDS<c>`.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    (result, carry, overflow) = AddWithCarry(SP, imm32, '0');
    if d == 15 then          // Can only occur for ARM encoding
        ALUWritePC(result);  // setflags is always FALSE here
    else
        R[d] = result;
        if setflags then
            APSR.N = result<31>;
            APSR.Z = IsZeroBit(result);
            APSR.C = carry;
            APSR.V = overflow;
```

Exceptions

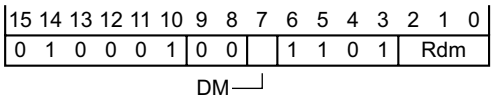
None.

A8.8.10 ADD (SP plus register, Thumb)

This instruction adds an optionally-shifted register value to the SP value, and writes the result to the destination register.

Encoding T1 ARMv4T, ARMv5T*, ARMv6*, ARMv7

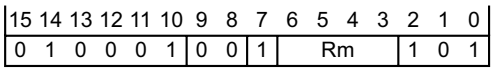
```
ADD<c> <Rdm>, SP, <Rdm>
```



```
d = UInt(DM:Rdm);  m = UInt(DM:Rdm);  setflags = FALSE;
if d == 15 && InITBlock() && !LastInITBlock() then UNPREDICTABLE;
(shift_t, shift_n) = (SRType_LSL, 0);
```

Encoding T2 ARMv4T, ARMv5T*, ARMv6*, ARMv7

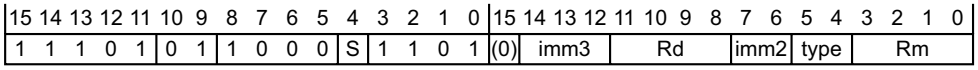
```
ADD<c> SP, <Rm>
```



```
if Rm == '1101' then SEE encoding T1;
d = 13;  m = UInt(Rm);  setflags = FALSE;
(shift_t, shift_n) = (SRType_LSL, 0);
```

Encoding T3 ARMv6T2, ARMv7

```
ADD{S}<c>.W <Rd>, SP, <Rm>{, <shift>}
```



```
if Rd == '1111' && S == '1' then SEE CMN (register);
d = UInt(Rd);  m = UInt(Rm);  setflags = (S == '1');
(shift_t, shift_n) = DecodeImmShift(type, imm3:imm2);
if d == 13 && (shift_t != SRType_LSL || shift_n > 3) then UNPREDICTABLE;
if (d == 15 && S == '0') || m IN {13,15} then UNPREDICTABLE;
```

Assembler syntax

```
ADD{S}{<c>}{<q>}  {<Rd>,} SP, <Rm>{, <shift>}
```

where:

S — If S is present, the instruction updates the flags. Otherwise, the flags are not updated.

<c>, <q> — See *Standard assembler syntax fields* on page A8-287.

<Rd> — The destination register. If S is specified and <Rd> is the PC, see *CMN (register)* on page A8-366. This register can be SP. If omitted, <Rd> is SP. This register can be the PC, but if it is, encoding T3 is not permitted. ARM deprecates using the PC.

If <Rd> is the PC and S is not specified, encoding T1 is used and the instruction is a branch to the address calculated by the operation. This is a simple branch, see *Pseudocode details of operations on ARM core registers* on page A2-47.

<Rm> — The register that is optionally shifted and used as the second operand. This register can be the PC, but if it is, encoding T3 is not permitted. ARM deprecates using the PC. This register can be the SP, but:

- ARM deprecates using the SP
- only encoding T1 is available and so the instruction can only be `ADD SP, SP, SP`.

<shift> — The shift to apply to the value read from <Rm>. If omitted, no shift is applied and any encoding is permitted. If present, only encoding T3 is permitted. *Shifts applied to a register* on page A8-291 describes the shifts and how they are encoded.

If <Rd> is SP or omitted, <shift> is only permitted to be omitted, `LSL #1`, `LSL #2`, or `LSL #3`.

The pre-UAL syntax `ADD<c>S` is equivalent to `ADDS<c>`.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shifted = Shift(R[m], shift_t, shift_n, APSR.C);
    (result, carry, overflow) = AddWithCarry(SP, shifted, '0');
    if d == 15 then
        ALUWritePC(result);  // setflags is always FALSE here
    else
        R[d] = result;
        if setflags then
            APSR.N = result<31>;
            APSR.Z = IsZeroBit(result);
            APSR.C = carry;
            APSR.V = overflow;
```

Exceptions

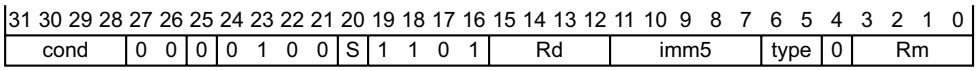
None.

A8.8.11 ADD (SP plus register, ARM)

This instruction adds an optionally-shifted register value to the SP value, and writes the result to the destination register.

Encoding A1 ARMv4*, ARMv5T*, ARMv6*, ARMv7

```
ADD{S}<c> <Rd>, SP, <Rm>{, <shift>}
```



```
if Rd == '1111' && S == '1' then SEE SUBS PC, LR and related instructions;
d = UInt(Rd);  m = UInt(Rm);  setflags = (S == '1');
(shift_t, shift_n) = DecodeImmShift(type, imm5);
```

Assembler syntax

```
ADD{S}{<c>}{<q>}  {<Rd>,} SP, <Rm>{, <shift>}
```

where:

S — If S is present, the instruction updates the flags. Otherwise, the flags are not updated.

<c>, <q> — See *Standard assembler syntax fields* on page A8-287.

<Rd> — The destination register. If S is specified and <Rd> is the PC, see *SUBS PC, LR and related instructions (ARM)* on page B9-2010. This register can be SP. If omitted, <Rd> is SP. This register can be the PC, but ARM deprecates using the PC.

If S is not specified and <Rd> is the PC, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode details of operations on ARM core registers* on page A2-47.

Note

Before ARMv7, this was a simple branch.

<Rm> — The register that is optionally shifted and used as the second operand. This register can be the PC, but ARM deprecates using the PC. This register can be the SP, but ARM deprecates using the SP.

<shift> — The shift to apply to the value read from <Rm>. If omitted, no shift is applied and any encoding is permitted. *Shifts applied to a register* on page A8-291 describes the shifts and how they are encoded.

The pre-UAL syntax ADD<c>S is equivalent to ADDS<c>.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shifted = Shift(R[m], shift_t, shift_n, APSR.C);
    (result, carry, overflow) = AddWithCarry(SP, shifted, '0');
    if d == 15 then
        ALUWritePC(result);  // setflags is always FALSE here
    else
        R[d] = result;
        if setflags then
            APSR.N = result<31>;
            APSR.Z = IsZeroBit(result);
            APSR.C = carry;
            APSR.V = overflow;
```

Exceptions

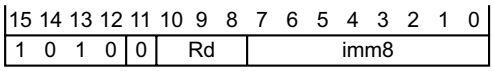
None.

A8.8.12 ADR

This instruction adds an immediate value to the PC value to form a PC-relative address, and writes the result to the destination register.

Encoding T1 ARMv4T, ARMv5T*, ARMv6*, ARMv7

```
ADR<c> <Rd>, <label>
```

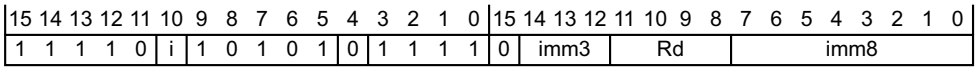


```
d = UInt(Rd);  imm32 = ZeroExtend(imm8:'00', 32);  add = TRUE;
```

Encoding T2 ARMv6T2, ARMv7

```
ADR<c>.W <Rd>, <label>
```
<label> before current instruction

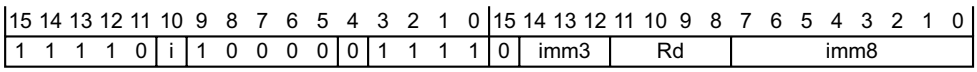
```
SUB <Rd>, PC, #0
```
Special case for subtraction of zero



```
d = UInt(Rd);  imm32 = ZeroExtend(i:imm3:imm8, 32);  add = FALSE;
if d IN {13,15} then UNPREDICTABLE;
```

Encoding T3 ARMv6T2, ARMv7

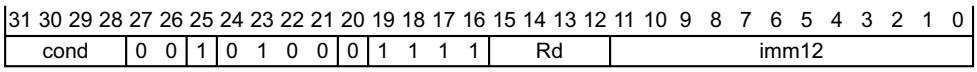
```
ADR<c>.W <Rd>, <label>
```
<label> after current instruction



```
d = UInt(Rd);  imm32 = ZeroExtend(i:imm3:imm8, 32);  add = TRUE;
if d IN {13,15} then UNPREDICTABLE;
```

Encoding A1 ARMv4*, ARMv5T*, ARMv6*, ARMv7

```
ADR<c> <Rd>, <label>
```
<label> after current instruction

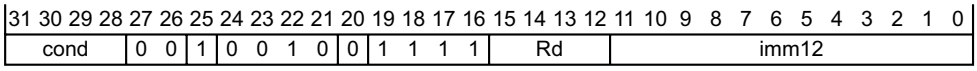


```
d = UInt(Rd);  imm32 = ARMExpandImm(imm12);  add = TRUE;
```

Encoding A2 ARMv4*, ARMv5T*, ARMv6*, ARMv7

```
ADR<c> <Rd>, <label>
```
<label> before current instruction

```
SUB <Rd>, PC, #0
```
Special case for subtraction of zero



```
d = UInt(Rd);  imm32 = ARMExpandImm(imm12);  add = FALSE;
```

Assembler syntax

`ADR{<c>}{<q>}`	`<Rd>, <label>`	Normal syntax
`ADD{<c>}{<q>}`	`<Rd>, PC, #<const>`	Alternative for encodings T1, T3, A1
`SUB{<c>}{<q>}`	`<Rd>, PC, #<const>`	Alternative for encoding T2, A2

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287.

`<Rd>` The destination register. In ARM instructions, if `<Rd>` is the PC, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode details of operations on ARM core registers* on page A2-47.

Note

Before ARMv7, this was a simple branch.

`<label>` The label of an instruction or literal data item whose address is to be loaded into `<Rd>`. The assembler calculates the required value of the offset from the `Align(PC, 4)` value of the `ADR` instruction to this label.

If the offset is zero or positive, encodings T1, T3, and A1 are permitted, with `imm32` equal to the offset.

If the offset is negative, encodings T2 and A2 are permitted, with `imm32` equal to the size of the offset. That is, the use of encoding T2 or A2 indicates that the required offset is minus the value of `imm32`.

Permitted values of the size of the offset are:

Encoding T1	Multiples of 4 in the range 0 to 1020.
Encodings T2, T3	Any value in the range 0 to 4095.
Encodings A1, A2	Any of the constants described in *Modified immediate constants in ARM instructions* on page A5-200.

The alternative syntax permits the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see *Use of labels in UAL instruction syntax* on page A4-162.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    result = if add then (Align(PC,4) + imm32) else (Align(PC,4) - imm32);
    if d == 15 then          // Can only occur for ARM encodings
        ALUWritePC(result);
    else
        R[d] = result;
```

Exceptions

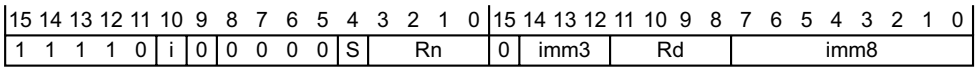
None.

A8.8.13 AND (immediate)

This instruction performs a bitwise AND of a register value and an immediate value, and writes the result to the destination register.

Encoding T1 ARMv6T2, ARMv7

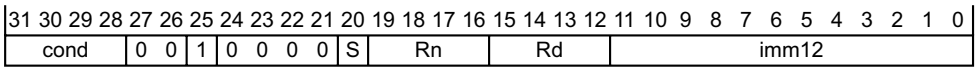
```
AND{S}<c> <Rd>, <Rn>, #<const>
```



```
if Rd == '1111' && S == '1' then SEE TST (immediate);
d = UInt(Rd);  n = UInt(Rn);  setflags = (S == '1');
(imm32, carry) = ThumbExpandImm_C(i:imm3:imm8, APSR.C);
if d == 13 || (d == 15 && S == '0') || n IN {13,15} then UNPREDICTABLE;
```

Encoding A1 ARMv4*, ARMv5T*, ARMv6*, ARMv7

```
AND{S}<c> <Rd>, <Rn>, #<const>
```



```
if Rd == '1111' && S == '1' then SEE SUBS PC, LR and related instructions;
d = UInt(Rd);  n = UInt(Rn);  setflags = (S == '1');
(imm32, carry) = ARMExpandImm_C(imm12, APSR.C);
```

Assembler syntax

```
AND{S}{<c>}{<q>}  {<Rd>,} <Rn>, #<const>
```

where:

S — If S is present, the instruction updates the flags. Otherwise, the flags are not updated.

<c>, <q> — See *Standard assembler syntax fields* on page A8-287.

<Rd> — The destination register. If S is specified and <Rd> is the PC, see *SUBS PC, LR (Thumb)* on page B9-2008 or *SUBS PC, LR and related instructions (ARM)* on page B9-2010.

In ARM instructions, if S is not specified and <Rd> is the PC, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode details of operations on ARM core registers* on page A2-47.

Note

Before ARMv7, this was a simple branch.

<Rn> — The first operand register. The PC can be used in ARM instructions.

<const> — The immediate value to be ANDed with the value obtained from <Rn>. See *Modified immediate constants in Thumb instructions* on page A6-232 or *Modified immediate constants in ARM instructions* on page A5-200 for the range of values.

The pre-UAL syntax AND<c>S is equivalent to ANDS<c>.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    result = R[n] AND imm32;
    if d == 15 then          // Can only occur for ARM encoding
        ALUWritePC(result);  // setflags is always FALSE here
    else
        R[d] = result;
        if setflags then
            APSR.N = result<31>;
            APSR.Z = IsZeroBit(result);
            APSR.C = carry;
            // APSR.V unchanged
```

Exceptions

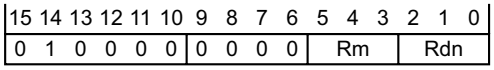
None.

A8.8.14 AND (register)

This instruction performs a bitwise AND of a register value and an optionally-shifted register value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

Encoding T1 ARMv4T, ARMv5T*, ARMv6*, ARMv7

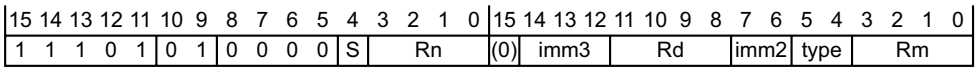
```
ANDS   <Rdn>, <Rm>          Outside IT block.
AND<c> <Rdn>, <Rm>          Inside IT block.
```



```
d = UInt(Rdn);  n = UInt(Rdn);  m = UInt(Rm);  setflags = !InITBlock();
(shift_t, shift_n) = (SRType_LSL, 0);
```

Encoding T2 ARMv6T2, ARMv7

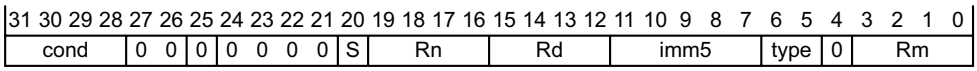
```
AND{S}<c>.W <Rd>, <Rn>, <Rm>{, <shift>}
```



```
if Rd == '1111' && S == '1' then SEE TST (register);
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  setflags = (S == '1');
(shift_t, shift_n) = DecodeImmShift(type, imm3:imm2);
if d == 13 || (d == 15 && S == '0') || n IN {13,15} || m IN {13,15} then UNPREDICTABLE;
```

Encoding A1 ARMv4*, ARMv5T*, ARMv6*, ARMv7

```
AND{S}<c> <Rd>, <Rn>, <Rm>{, <shift>}
```



```
if Rd == '1111' && S == '1' then SEE SUBS PC, LR and related instructions;
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  setflags = (S == '1');
(shift_t, shift_n) = DecodeImmShift(type, imm5);
```

Assembler syntax

```
AND{S}{<c>}{<q>}  {<Rd>,} <Rn>, <Rm> {, <shift>}
```

where:

S	If S is present, the instruction updates the flags. Otherwise, the flags are not updated.
<c>, <q>	See *Standard assembler syntax fields* on page A8-287.
<Rd>	The destination register. If S is specified and <Rd> is the PC, see *SUBS PC, LR (Thumb)* on page B9-2008 or *SUBS PC, LR and related instructions (ARM)* on page B9-2010. In ARM instructions, if S is not specified and <Rd> is the PC, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode details of operations on ARM core registers* on page A2-47. **Note** Before ARMv7, this was a simple branch.
<Rn>	The first operand register. The PC can be used in ARM instructions.
<Rm>	The register that is optionally shifted and used as the second operand. The PC can be used in ARM instructions.
<shift>	The shift to apply to the value read from <Rm>. If present, encoding T1 is not permitted. If absent, no shift is applied and all encodings are permitted. *Shifts applied to a register* on page A8-291 describes the shifts and how they are encoded.

In Thumb assembly:

- outside an IT block, if `ANDS <Rd>, <Rn>, <Rd>` has <Rd> and <Rn> both in the range R0-R7, it is assembled using encoding T1 as though `ANDS <Rd>, <Rn>` had been written
- inside an IT block, if `AND<c> <Rd>, <Rn>, <Rd>` has <Rd> and <Rn> both in the range R0-R7, it is assembled using encoding T1 as though `AND<c> <Rd>, <Rn>` had been written.

To prevent either of these happening, use the .W qualifier.

The pre-UAL syntax `AND<c>S` is equivalent to `ANDS<c>`.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    (shifted, carry) = Shift_C(R[m], shift_t, shift_n, APSR.C);
    result = R[n] AND shifted;
    if d == 15 then          // Can only occur for ARM encoding
        ALUWritePC(result);  // setflags is always FALSE here
    else
        R[d] = result;
        if setflags then
            APSR.N = result<31>;
            APSR.Z = IsZeroBit(result);
            APSR.C = carry;
            // APSR.V unchanged
```

Exceptions

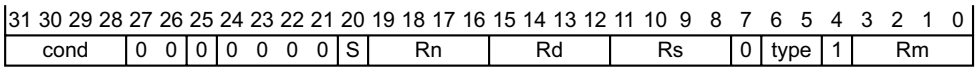
None.

A8.8.15 AND (register-shifted register)

This instruction performs a bitwise AND of a register value and a register-shifted register value. It writes the result to the destination register, and can optionally update the condition flags based on the result.

Encoding A1 ARMv4*, ARMv5T*, ARMv6*, ARMv7

```
AND{S}<c> <Rd>, <Rn>, <Rm>, <type> <Rs>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  s = UInt(Rs);
setflags = (S == '1');  shift_t = DecodeRegShift(type);
if d == 15 || n == 15 || m == 15 || s == 15 then UNPREDICTABLE;
```

Assembler syntax

```
AND{S}{<c>}{<q>}  {<Rd>,} <Rn>, <Rm>, <type>  <Rs>
```

where:

S — If S is present, the instruction updates the flags. Otherwise, the flags are not updated.

<c>, <q> — See *Standard assembler syntax fields* on page A8-287.

<Rd> — The destination register.

<Rn> — The first operand register.

<Rm> — The register that is shifted and used as the second operand.

<type> — The type of shift to apply to the value read from <Rm>. It must be one of:

- ASR — Arithmetic shift right, encoded as type = 0b10.
- LSL — Logical shift left, encoded as type = 0b00.
- LSR — Logical shift right, encoded as type = 0b01.
- ROR — Rotate right, encoded as type = 0b11.

<Rs> — The register whose bottom byte contains the amount to shift by.

The pre-UAL syntax AND<c>S is equivalent to ANDS<c>.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shift_n = UInt(R[s]<7:0>);
    (shifted, carry) = Shift_C(R[m], shift_t, shift_n, APSR.C);
    result = R[n] AND shifted;
    R[d] = result;
    if setflags then
        APSR.N = result<31>;
        APSR.Z = IsZeroBit(result);
        APSR.C = carry;
        // APSR.V unchanged
```

Exceptions

None.

A8.8.16 ASR (immediate)

Arithmetic Shift Right (immediate) shifts a register value right by an immediate number of bits, shifting in copies of its sign bit, and writes the result to the destination register. It can optionally update the condition flags based on the result.

Encoding T1 ARMv4T, ARMv5T*, ARMv6*, ARMv7

```
ASRS <Rd>, <Rm>, #<imm>                    Outside IT block.
ASR<c> <Rd>, <Rm>, #<imm>                  Inside IT block.
```

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	1	0	imm5					Rm			Rd		

```
d = UInt(Rd);  m = UInt(Rm);  setflags = !InITBlock();
(-, shift_n) = DecodeImmShift('10', imm5);
```

Encoding T2 ARMv6T2, ARMv7

```
ASR{S}<c>.W <Rd>, <Rm>, #<imm>
```

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	0	1	0	1	0	0	1	0	S	1	1	1	1	(0)	imm3			Rd				imm2		1	0	Rm			

```
d = UInt(Rd);  m = UInt(Rm);  setflags = (S == '1');
(-, shift_n) = DecodeImmShift('10', imm3:imm2);
if d IN {13,15} || m IN {13,15} then UNPREDICTABLE;
```

Encoding A1 ARMv4*, ARMv5T*, ARMv6*, ARMv7

```
ASR{S}<c> <Rd>, <Rm>, #<imm>
```

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond				0	0	0	1	1	0	1	S	(0)	(0)	(0)	(0)	Rd				imm5					1	0	0	Rm			

```
if Rd == '1111' && S == '1' then SEE SUBS PC, LR and related instructions;
d = UInt(Rd);  m = UInt(Rm);  setflags = (S == '1');
(-, shift_n) = DecodeImmShift('10', imm5);
```

Assembler syntax

```
ASR{S}{<c>}{<q>}  {<Rd>,} <Rm>, #<imm>
```

where:

S — If S is present, the instruction updates the flags. Otherwise, the flags are not updated.

<c>, <q> — See *Standard assembler syntax fields* on page A8-287.

<Rd> — The destination register.

In ARM instructions, if S is not specified and <Rd> is the PC, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode details of operations on ARM core registers* on page A2-47.

Note

Before ARMv7, this was a simple branch.

<Rm> — The first operand register. The PC can be used in ARM instructions.

<imm> — The shift amount, in the range 1 to 32. See *Shifts applied to a register* on page A8-291.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    (result, carry) = Shift_C(R[m], SRType_ASR, shift_n, APSR.C);
    if d == 15 then          // Can only occur for ARM encoding
        ALUWritePC(result);  // setflags is always FALSE here
    else
        R[d] = result;
        if setflags then
            APSR.N = result<31>;
            APSR.Z = IsZeroBit(result);
            APSR.C = carry;
            // APSR.V unchanged
```

Exceptions

None.

A8.8.17 ASR (register)

Arithmetic Shift Right (register) shifts a register value right by a variable number of bits, shifting in copies of its sign bit, and writes the result to the destination register. The variable number of bits is read from the bottom byte of a register. It can optionally update the condition flags based on the result.

Encoding T1 ARMv4T, ARMv5T*, ARMv6*, ARMv7

```
ASRS   <Rdn>, <Rm>                    Outside IT block.
ASR<c> <Rdn>, <Rm>                    Inside IT block.
```

        APSR.Z = IsZeroBit(result);
        APSR.C = carry;
        // APSR.V unchanged
```

Exceptions

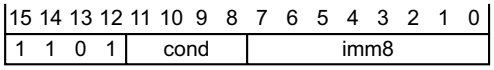
None.

A8.8.18 B

Branch causes a branch to a target address.

Encoding T1 ARMv4T, ARMv5T*, ARMv6*, ARMv7

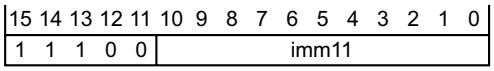
`B<c> <label>` Not permitted in IT block.



```
if cond == '1110' then UNDEFINED;
if cond == '1111' then SEE SVC;
imm32 = SignExtend(imm8:'0', 32);
if InITBlock() then UNPREDICTABLE;
```

Encoding T2 ARMv4T, ARMv5T*, ARMv6*, ARMv7

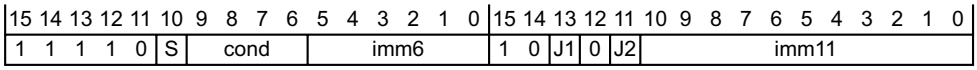
`B<c> <label>` Outside or last in IT block



```
imm32 = SignExtend(imm11:'0', 32);
if InITBlock() && !LastInITBlock() then UNPREDICTABLE;
```

Encoding T3 ARMv6T2, ARMv7

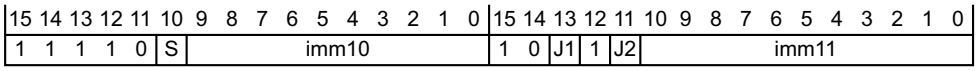
`B<c>.W <label>` Not permitted in IT block.



```
if cond<3:1> == '111' then SEE "Related encodings";
imm32 = SignExtend(S:J2:J1:imm6:imm11:'0', 32);
if InITBlock() then UNPREDICTABLE;
```

Encoding T4 ARMv6T2, ARMv7

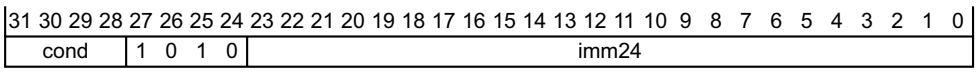
`B<c>.W <label>` Outside or last in IT block



```
I1 = NOT(J1 EOR S);  I2 = NOT(J2 EOR S);  imm32 = SignExtend(S:I1:I2:imm10:imm11:'0', 32);
if InITBlock() && !LastInITBlock() then UNPREDICTABLE;
```

Encoding A1 ARMv4*, ARMv5T*, ARMv6*, ARMv7

`B<c> <label>`



```
imm32 = SignExtend(imm24:'00', 32);
```

Related encodings See *Branches and miscellaneous control* on page A6-235.

Assembler syntax

```
B{<c>}{<q>}  <label>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287.

Note

Encodings T1 and T3 are conditional in their own right, and do not require an `IT` instruction to make them conditional.

For encodings T1 and T3, `<c>` must not be `AL` or omitted. The 4-bit encoding of the condition is placed in the instruction and not in a preceding `IT` instruction, and the instruction must not be in an IT block. As a result, encodings T1 and T2 are never both available to the assembler, nor are encodings T3 and T4.

`<label>` The label of the instruction that is to be branched to. The assembler calculates the required value of the offset from the PC value of the `B` instruction to this label, then selects an encoding that sets `imm32` to that offset.

Permitted offsets are:

Encoding T1	Even numbers in the range –256 to 254
Encoding T2	Even numbers in the range –2048 to 2046
Encoding T3	Even numbers in the range –1048576 to 1048574
Encoding T4	Even numbers in the range –16777216 to 16777214
Encoding A1	Multiples of 4 in the range –33554432 to 33554428.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    BranchWritePC(PC + imm32);
```

Exceptions

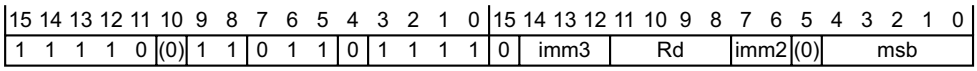
None.

A8.8.19 BFC

Bit Field Clear clears any number of adjacent bits at any position in a register, without affecting the other bits in the register.

Encoding T1 ARMv6T2, ARMv7

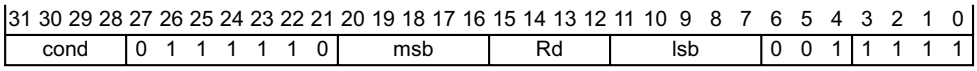
```
BFC<c> <Rd>, #<lsb>, #<width>
```



```
d = UInt(Rd);  msbit = UInt(msb);  lsbit = UInt(imm3:imm2);
if d IN {13,15} then UNPREDICTABLE;
```

Encoding A1 ARMv6T2, ARMv7

```
BFC<c> <Rd>, #<lsb>, #<width>
```



```
d = UInt(Rd);  msbit = UInt(msb);  lsbit = UInt(lsb);
if d == 15 then UNPREDICTABLE;
```

Assembler syntax

```
BFC{<c>}{<q>}  <Rd>, #<lsb>, #<width>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287.

`<Rd>` The destination register.

`<lsb>` The least significant bit that is to be cleared, in the range 0 to 31. This determines the required value of `lsbit`.

`<width>` The number of bits to be cleared, in the range 1 to 32-`<lsb>`. The required value of `msbit` is `<lsb>+<width>-1`.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if msbit >= lsbit then
        R[d]<msbit:lsbit> = Replicate('0', msbit-lsbit+1);
        // Other bits of R[d] are unchanged
    else
        UNPREDICTABLE;
```

Exceptions

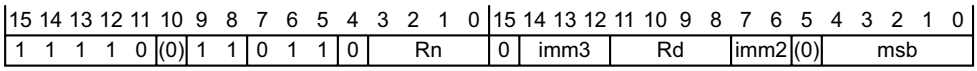
None.

A8.8.20 BFI

Bit Field Insert copies any number of low order bits from a register into the same number of adjacent bits at any position in the destination register.

Encoding T1 ARMv6T2, ARMv7

```
BFI<c> <Rd>, <Rn>, #<lsb>, #<width>
```

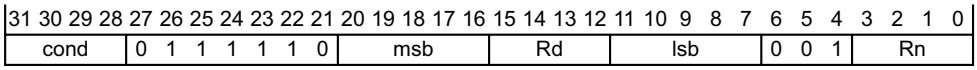


15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	0	(0)	1	1	0	1	1	0	Rn				0	imm3			Rd				imm2		(0)	msb				

```
if Rn == '1111' then SEE BFC;
d = UInt(Rd);  n = UInt(Rn);  msbit = UInt(msb);  lsbit = UInt(imm3:imm2);
if d IN {13,15} || n == 13 then UNPREDICTABLE;
```

Encoding A1 ARMv6T2, ARMv7

```
BFI<c> <Rd>, <Rn>, #<lsb>, #<width>
```



31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond				0	1	1	1	1	1	0	msb					Rd				lsb					0	0	1	Rn			

```
if Rn == '1111' then SEE BFC;
d = UInt(Rd);  n = UInt(Rn);  msbit = UInt(msb);  lsbit = UInt(lsb);
if d == 15 then UNPREDICTABLE;
```

Assembler syntax

```
BFI{<c>}{<q>}  <Rd>, <Rn>, #<lsb>, #<width>
```

where:

`<c>, <q>`	See *Standard assembler syntax fields* on page A8-287.
`<Rd>`	The destination register.
`<Rn>`	The source register.
`<lsb>`	The least significant destination bit, in the range 0 to 31. This determines the required value of `lsbit`.
`<width>`	The number of bits to be copied, in the range 1 to 32-`<lsb>`. The required value of `msbit` is `<lsb>+<width>-1`.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if msbit >= lsbit then
        R[d]<msbit:lsbit> = R[n]<(msbit-lsbit):0>;
        // Other bits of R[d] are unchanged
    else
        UNPREDICTABLE;
```

Exceptions

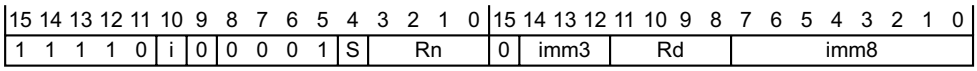
None.

A8.8.21 BIC (immediate)

Bitwise Bit Clear (immediate) performs a bitwise AND of a register value and the complement of an immediate value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

Encoding T1 ARMv6T2, ARMv7

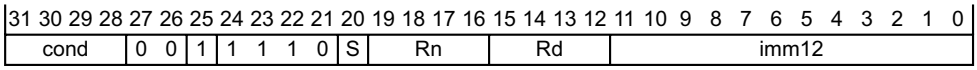
```
BIC{S}<c> <Rd>, <Rn>, #<const>
```



```
d = UInt(Rd);  n = UInt(Rn);  setflags = (S == '1');
(imm32, carry) = ThumbExpandImm_C(i:imm3:imm8, APSR.C);
if d IN {13,15} || n IN {13,15} then UNPREDICTABLE;
```

Encoding A1 ARMv4*, ARMv5T*, ARMv6*, ARMv7

```
BIC{S}<c> <Rd>, <Rn>, #<const>
```



```
if Rd == '1111' && S == '1' then SEE SUBS PC, LR and related instructions;
d = UInt(Rd);  n = UInt(Rn);  setflags = (S == '1');
(imm32, carry) = ARMExpandImm_C(imm12, APSR.C);
```

Assembler syntax

```
BIC{S}{<c>}{<q>}  {<Rd>,} <Rn>, #<const>
```

where:

S — If S is present, the instruction updates the flags. Otherwise, the flags are not updated.

<c>, <q> — See *Standard assembler syntax fields* on page A8-287.

<Rd> — The destination register. If S is specified and <Rd> is the PC, see *SUBS PC, LR (Thumb)* on page B9-2008 or *SUBS PC, LR and related instructions (ARM)* on page B9-2010.

In ARM instructions, if S is not specified and <Rd> is the PC, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode details of operations on ARM core registers* on page A2-47.

Note

Before ARMv7, this was a simple branch.

<Rn> — The register that contains the operand. The PC can be used in ARM instructions.

<const> — The immediate value to be bitwise inverted and ANDed with the value obtained from <Rn>. See *Modified immediate constants in Thumb instructions* on page A6-232 or *Modified immediate constants in ARM instructions* on page A5-200 for the range of values.

The pre-UAL syntax BIC<c>S is equivalent to BICS<c>.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    result = R[n] AND NOT(imm32);
    if d == 15 then          // Can only occur for ARM encoding
        ALUWritePC(result);  // setflags is always FALSE here
    else
        R[d] = result;
        if setflags then
            APSR.N = result<31>;
            APSR.Z = IsZeroBit(result);
            APSR.C = carry;
            // APSR.V unchanged
```

Exceptions

None.

A8.8.22 BIC (register)

Bitwise Bit Clear (register) performs a bitwise AND of a register value and the complement of an optionally-shifted register value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

Encoding T1 ARMv4T, ARMv5T*, ARMv6*, ARMv7

```
BICS   <Rdn>, <Rm>                    Outside IT block.
BIC<c> <Rdn>, <Rm>                    Inside IT block.
```

if Rd == '1111' && S == '1' then SEE SUBS PC, LR and related instructions;
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  setflags = (S == '1');
(shift_t, shift_n) = DecodeImmShift(type, imm5);
```

Assembler syntax

```
BIC{S}{<c>}{<q>}  {<Rd>,} <Rn>, <Rm> {, <shift>}
```

where:

S — If S is present, the instruction updates the flags. Otherwise, the flags are not updated.

<c>, <q> — See *Standard assembler syntax fields* on page A8-287.

<Rd> — The destination register. If S is specified and <Rd> is the PC, see *SUBS PC, LR (Thumb)* on page B9-2008 or *SUBS PC, LR and related instructions (ARM)* on page B9-2010.

In ARM instructions, if S is not specified and <Rd> is the PC, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode details of operations on ARM core registers* on page A2-47.

Note

Before ARMv7, this was a simple branch.

<Rn> — The first operand register. The PC can be used in ARM instructions.

<Rm> — The register that is optionally shifted and used as the second operand. The PC can be used in ARM instructions.

<shift> — The shift to apply to the value read from <Rm>. If present, encoding T1 is not permitted. If absent, no shift is applied and all encodings are permitted. *Shifts applied to a register* on page A8-291 describes the shifts and how they are encoded.

The pre-UAL syntax BIC<c>S is equivalent to BICS<c>.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    (shifted, carry) = Shift_C(R[m], shift_t, shift_n, APSR.C);
    result = R[n] AND NOT(shifted);
    if d == 15 then          // Can only occur for ARM encoding
        ALUWritePC(result);  // setflags is always FALSE here
    else
        R[d] = result;
        if setflags then
            APSR.N = result<31>;
            APSR.Z = IsZeroBit(result);
            APSR.C = carry;
            // APSR.V unchanged
```

Exceptions

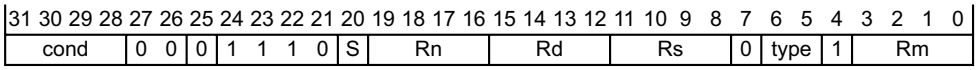
None.

A8.8.23 BIC (register-shifted register)

Bitwise Bit Clear (register-shifted register) performs a bitwise AND of a register value and the complement of a register-shifted register value. It writes the result to the destination register, and can optionally update the condition flags based on the result.

Encoding A1 ARMv4*, ARMv5T*, ARMv6*, ARMv7

```
BIC{S}<c> <Rd>, <Rn>, <Rm>, <type> <Rs>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  s = UInt(Rs);
setflags = (S == '1');  shift_t = DecodeRegShift(type);
if d == 15 || n == 15 || m == 15 || s == 15 then UNPREDICTABLE;
```

Assembler syntax

```
BIC{S}{<c>}{<q>}  {<Rd>,} <Rn>, <Rm>, <type>  <Rs>
```

where:

S — If S is present, the instruction updates the flags. Otherwise, the flags are not updated.

<c>, <q> — See *Standard assembler syntax fields* on page A8-287.

<Rd> — The destination register.

<Rn> — The first operand register.

<Rm> — The register that is shifted and used as the second operand.

<type> — The type of shift to apply to the value read from <Rm>. It must be one of:

- ASR — Arithmetic shift right, encoded as type = 0b10.
- LSL — Logical shift left, encoded as type = 0b00.
- LSR — Logical shift right, encoded as type = 0b01.
- ROR — Rotate right, encoded as type = 0b11.

<Rs> — The register whose bottom byte contains the amount to shift by.

The pre-UAL syntax BIC<c>S is equivalent to BICS<c>.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shift_n = UInt(R[s]<7:0>);
    (shifted, carry) = Shift_C(R[m], shift_t, shift_n, APSR.C);
    result = R[n] AND NOT(shifted);
    R[d] = result;
    if setflags then
        APSR.N = result<31>;
        APSR.Z = IsZeroBit(result);
        APSR.C = carry;
        // APSR.V unchanged
```

Exceptions

None.

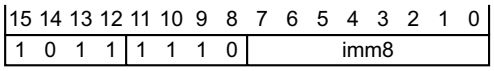
A8.8.24 BKPT

Breakpoint causes a software breakpoint to occur.

Breakpoint is always unconditional, even when inside an IT block.

Encoding T1 ARMv5T*, ARMv6*, ARMv7

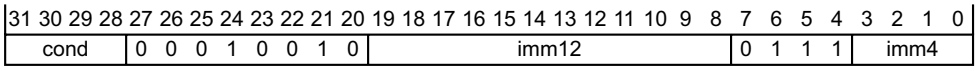
```
BKPT #<imm8>
```



```
imm32 = ZeroExtend(imm8, 32);
// imm32 is for assembly/disassembly only and is ignored by hardware.
```

Encoding A1 ARMv5T*, ARMv6*, ARMv7

```
BKPT #<imm16>
```



```
imm32 = ZeroExtend(imm12:imm4, 32);
// imm32 is for assembly/disassembly only and is ignored by hardware.
if cond != '1110' then UNPREDICTABLE;  // BKPT must be encoded with AL condition
```

Assembler syntax

```
BKPT{<q>}  {#}<imm>
```

where:

<q> See *Standard assembler syntax fields* on page A8-287. A BKPT instruction must be unconditional.

<imm> Specifies a value that is stored in the instruction, in the range 0-255 for a Thumb instruction or 0-65535 for an ARM instruction. This value is ignored by the processor, but can be used by a debugger to store more information about the breakpoint.

Operation

```
EncodingSpecificOperations();
BKPTInstrDebugEvent();
```

Exceptions

Prefetch Abort.

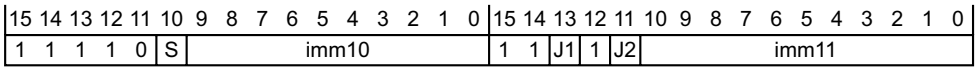
A8.8.25 BL, BLX (immediate)

Branch with Link calls a subroutine at a PC-relative address.

Branch with Link and Exchange Instruction Sets (immediate) calls a subroutine at a PC-relative address, and changes instruction set from ARM to Thumb, or from Thumb to ARM.

Encoding T1 ARMv4T, ARMv5T*, ARMv6*, ARMv7 if J1 == J2 == 1
ARMv6T2, ARMv7 otherwise

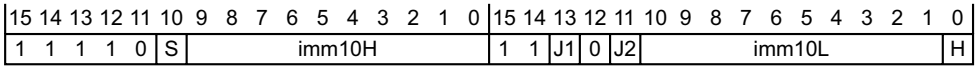
```
BL<c> <label>                                   Outside or last in IT block
```



```
I1 = NOT(J1 EOR S);  I2 = NOT(J2 EOR S);  imm32 = SignExtend(S:I1:I2:imm10:imm11:'0', 32);
targetInstrSet = CurrentInstrSet();
if InITBlock() && !LastInITBlock() then UNPREDICTABLE;
```

Encoding T2 ARMv5T*, ARMv6*, ARMv7 if J1 == J2 == 1
ARMv6T2, ARMv7 otherwise

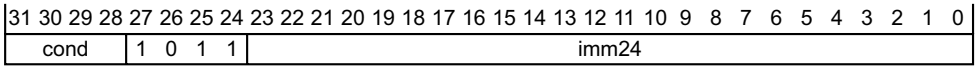
```
BLX<c> <label>                                  Outside or last in IT block
```



```
if CurrentInstrSet() == InstrSet_ThumbEE || H == '1' then UNDEFINED;
I1 = NOT(J1 EOR S);  I2 = NOT(J2 EOR S);  imm32 = SignExtend(S:I1:I2:imm10H:imm10L:'00', 32);
targetInstrSet = InstrSet_ARM;
if InITBlock() && !LastInITBlock() then UNPREDICTABLE;
```

Encoding A1 ARMv4*, ARMv5T*, ARMv6*, ARMv7

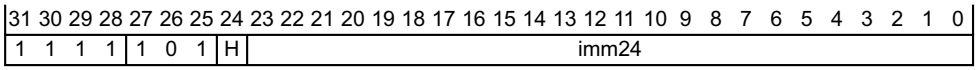
```
BL<c> <label>
```



```
imm32 = SignExtend(imm24:'00', 32);  targetInstrSet = InstrSet_ARM;
```

Encoding A2 ARMv5T*, ARMv6*, ARMv7

```
BLX <label>
```



```
imm32 = SignExtend(imm24:H:'0', 32);  targetInstrSet = InstrSet_Thumb;
```

Assembler syntax

```
BL{X}{<c>}{<q>}  <label>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287. An ARM `BLX` (immediate) instruction must be unconditional.

`X` If present, specifies a change of instruction set (from ARM to Thumb or from Thumb to ARM). If X is omitted, the processor remains in the same state. For ThumbEE instructions, specifying X is not permitted.

`<label>` The label of the instruction that is to be branched to.

`BL` uses encoding T1 or A1. The assembler calculates the required value of the offset from the PC value of the `BL` instruction to this label, then selects an encoding with `imm32` set to that offset.

`BLX` uses encoding T2 or A2. The assembler calculates the required value of the offset from the `Align(PC, 4)` value of the `BLX` instruction to this label, then selects an encoding with `imm32` set to that offset.

Permitted offsets are:

Encoding T1	Even numbers in the range –16777216 to 16777214.
Encoding T2	Multiples of 4 in the range –16777216 to 16777212.
Encoding A1	Multiples of 4 in the range –33554432 to 33554428.
Encoding A2	Even numbers in the range –33554432 to 33554430.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if CurrentInstrSet() == InstrSet_ARM then
        LR = PC - 4;
    else
        LR = PC<31:1> : '1';
    if targetInstrSet == InstrSet_ARM then
        targetAddress = Align(PC,4) + imm32;
    else
        targetAddress = PC + imm32;
    SelectInstrSet(targetInstrSet);
    BranchWritePC(targetAddress);
```

Exceptions

None.

Branch range before ARMv6T2

Before ARMv6T2, J1 and J2 in encodings T1 and T2 were both 1, resulting in a smaller branch range. The instructions could be executed as two separate 16-bit instructions, as described in *BL and BLX (immediate) instructions, before ARMv6T2* on page AppxL-2502.

A8.8.26 BLX (register)

Branch with Link and Exchange (register) calls a subroutine at an address and instruction set specified by a register.

Encoding T1 ARMv5T*, ARMv6*, ARMv7

`BLX<c> <Rm>` Outside or last in IT block

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	0	0	0	1	1	1	1	Rm				(0)	(0)	(0)

```
m = UInt(Rm);
if m == 15 then UNPREDICTABLE;
if InITBlock() && !LastInITBlock() then UNPREDICTABLE;
```

Encoding A1 ARMv5T*, ARMv6*, ARMv7

`BLX<c> <Rm>`

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond				0	0	0	1	0	0	1	0	(1)	(1)	(1)	(1)	(1)	(1)	(1)	(1)	(1)	(1)	(1)	(1)	0	0	1	1	Rm			

```
m = UInt(Rm);
if m == 15 then UNPREDICTABLE;
```

Assembler syntax

```
BLX{<c>}{<q>}  <Rm>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287.

`<Rm>` The register that contains the branch target address and instruction set selection bit. This register can be the SP in both ARM and Thumb instructions, but ARM deprecates this use of the SP.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    target = R[m];
    if CurrentInstrSet() == InstrSet_ARM then
        next_instr_addr = PC - 4;
        LR = next_instr_addr;
    else
        next_instr_addr = PC - 2;
        LR = next_instr_addr<31:1> : '1';
    BXWritePC(target);
```

Exceptions

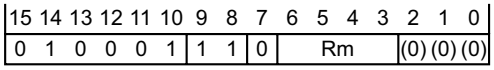
None.

A8.8.27 BX

Branch and Exchange causes a branch to an address and instruction set specified by a register.

Encoding T1 ARMv4T, ARMv5T*, ARMv6*, ARMv7

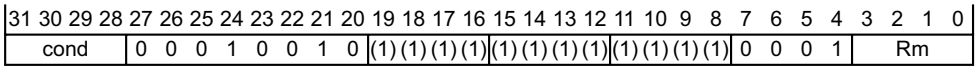
`BX<c> <Rm>` Outside or last in IT block



```
m = UInt(Rm);
if InITBlock() && !LastInITBlock() then UNPREDICTABLE;
```

Encoding A1 ARMv4T, ARMv5T*, ARMv6*, ARMv7

`BX<c> <Rm>`



```
m = UInt(Rm);
```

Assembler syntax

```
BX{<c>}{<q>}  <Rm>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287.

`<Rm>` The register that contains the branch target address and instruction set selection bit. The PC can be used. This register can be the SP in both ARM and Thumb instructions, but ARM deprecates this use of the SP.

Note

If `<Rm>` is the PC in a Thumb instruction at a non word-aligned address, it results in UNPREDICTABLE behavior because the address passed to the `BXWritePC()` pseudocode function has bits<1:0> = '10'.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    BXWritePC(R[m]);
```

Exceptions

None.

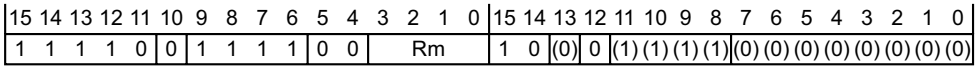
A8.8.28 BXJ

Branch and Exchange Jazelle attempts to change to Jazelle state. If the attempt fails, it branches to an address and instruction set specified by a register as though it were a `BX` instruction.

In an implementation that includes the Virtualization Extensions, if HSTR.TJDBX is set to 1, execution of a `BXJ` instruction in a Non-secure mode other than Hyp mode generates a Hyp Trap exception. For more information see *Trapping accesses to Jazelle functionality* on page B1-1255.

Encoding T1 ARMv6T2, ARMv7

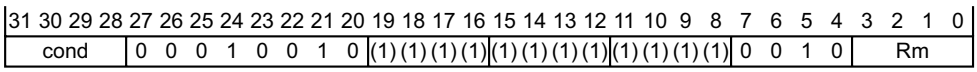
`BXJ<c> <Rm>` Outside or last in IT block



```
m = UInt(Rm);
if m IN {13,15} then UNPREDICTABLE;
if InITBlock() && !LastInITBlock() then UNPREDICTABLE;
```

Encoding A1 ARMv5TEJ, ARMv6*, ARMv7

`BXJ<c> <Rm>`



```
m = UInt(Rm);
if m == 15 then UNPREDICTABLE;
```

Assembler syntax

```
BXJ{<c>}{<q>}  <Rm>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287.

`<Rm>` The register that specifies the branch target address and instruction set selection bit to be used if the attempt to switch to Jazelle state fails.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if HaveVirtExt() && !IsSecure() && !CurrentModeIsHyp() && HSTR.TJDBX == '1' then
        HSRString = Zeros(25);
        HSRString<3:0> = m;
        WriteHSR('001010', HSRString);
        TakeHypTrapException();
    elsif JMCR.JE == '0' || CurrentInstrSet() == InstrSet_ThumbEE then
        BXWritePC(R[m]);
    else
        if JazelleAcceptsExecution() then
            SwitchToJazelleExecution();
        else
            SUBARCHITECTURE_DEFINED handler call;
```

Exceptions

Hyp Trap.

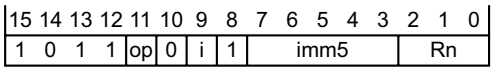
A8.8.29 CBNZ, CBZ

Compare and Branch on Nonzero and Compare and Branch on Zero compare the value in a register with zero, and conditionally branch forward a constant value. They do not affect the condition flags.

Encoding T1 ARMv6T2, ARMv7

```
CB{N}Z <Rn>, <label>
```

Not permitted in IT block.



```
n = UInt(Rn);  imm32 = ZeroExtend(i:imm5:'0', 32);  nonzero = (op == '1');
if InITBlock() then UNPREDICTABLE;
```

Assembler syntax

```
CB{N}Z{<q>}  <Rn>, <label>
```

where:

N	If specified, causes the branch to occur when the contents of <Rn> are nonzero (encoded as op = 1). If omitted, causes the branch to occur when the contents of <Rn> are zero (encoded as op = 0).
<q>	See *Standard assembler syntax fields* on page A8-287. A CBZ or CBNZ instruction must be unconditional.
<Rn>	The operand register.
<label>	The label of the instruction that is to be branched to. The assembler calculates the required value of the offset from the PC value of the CBZ or CBNZ instruction to this label, then selects an encoding that sets imm32 to that offset. Permitted offsets are even numbers in the range 0 to 126.

Operation

```
EncodingSpecificOperations();
if nonzero ^ IsZero(R[n]) then
    BranchWritePC(PC + imm32);
```

Exceptions

None.

A8.8.30 CDP, CDP2

Coprocessor Data Processing tells a coprocessor to perform an operation that is independent of ARM core registers and memory. If no coprocessor can execute the instruction, an Undefined Instruction exception is generated.

This is a generic coprocessor instruction. Some of the fields have no functionality defined by the architecture and are free for use by the coprocessor instruction set designer. These are the `opc1`, `opc2`, `CRd`, `CRn`, and `CRm` fields. However, coprocessors CP8-CP15 are reserved for use by ARM, and this manual defines the valid `CDP` and `CDP2` instructions when `coproc` is in the range `p8-p15`. For more information see *Coprocessor support* on page A2-94.

Encoding T1/A1 ARMv6T2, ARMv7 for encoding T1
ARMv4*, ARMv5T*, ARMv6*, ARMv7 for encoding A1

```
CDP<c> <coproc>, <opc1>, <CRd>, <CRn>, <CRm>, <opc2>
```

1	1	1	1	1	1	1	0	opc1				CRn				CRd				coproc				opc2			0	CRm			

```
cp = UInt(coproc);
```

Floating-point instructions See *Floating-point data-processing instructions* on page A7-272

Assembler syntax

```
CDP{2}{<c>}{<q>}  <coproc>, {#}<opc1>, <CRd>, <CRn>, <CRm> {, {#}<opc2>}
```

where:

2	If specified, selects encoding T2/A2. If omitted, selects encoding T1/A1.
<c>, <q>	See *Standard assembler syntax fields* on page A8-287. An ARM CDP2 instruction must be unconditional.
<coproc>	The name of the coprocessor, and causes the corresponding coprocessor number to be placed in the cp_num field of the instruction. The generic coprocessor names are p0-p15.
<opc1>	Is a coprocessor-specific opcode, in the range 0 to 15.
<CRd>	The destination coprocessor register for the instruction.
<CRn>	The coprocessor register that contains the first operand.
<CRm>	The coprocessor register that contains the second operand.
<opc2>	Is a coprocessor-specific opcode in the range 0 to 7. If it is omitted, <opc2> is 0.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if !Coproc_Accepted(cp, ThisInstr()) then
        GenerateCoprocessorException();
    else
        Coproc_InternalOperation(cp, ThisInstr());
```

Exceptions

Undefined Instruction.

Uses of these instructions by specific coprocessors might generate other exceptions.

A8.8.31 CHKA

CHKA is a ThumbEE instruction, see *CHKA* on page A9-1124.

A8.8.32 CLREX

Clear-Exclusive clears the local record of the executing processor that an address has had a request for an exclusive access.

Encoding T1 ARMv7

CLREX<c>

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	0	0	1	1	1	0	1	1	(1)	(1)	(1)	(1)	1	0	(0)	0	(1)	(1)	(1)	(1)	0	0	1	0	(1)	(1)	(1)	(1)

```
// No additional decoding required
```

Encoding A1 ARMv6K, ARMv7

CLREX

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	0	1	0	1	0	1	1	1	(1)	(1)	(1)	(1)	(1)	(1)	(1)	(1)	(0)	(0)	(0)	(0)	0	0	0	1	(1)	(1)	(1)	(1)

```
// No additional decoding required
```

Assembler syntax

```
CLREX{<c>}{<q>}
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287. An ARM `CLREX` instruction must be unconditional.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    ClearExclusiveLocal(ProcessorID());
```

Exceptions

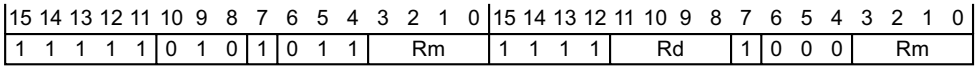
None.

A8.8.33 CLZ

Count Leading Zeros returns the number of binary zero bits before the first binary one bit in a value.

Encoding T1 ARMv6T2, ARMv7

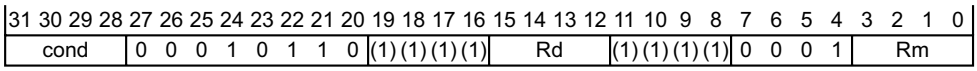
```
CLZ<c> <Rd>, <Rm>
```



```
if !Consistent(Rm) then UNPREDICTABLE;
d = UInt(Rd);  m = UInt(Rm);
if d IN {13,15} || m IN {13,15} then UNPREDICTABLE;
```

Encoding A1 ARMv5T*, ARMv6*, ARMv7

```
CLZ<c> <Rd>, <Rm>
```



```
d = UInt(Rd);  m = UInt(Rm);
if d == 15 || m == 15 then UNPREDICTABLE;
```

Assembler syntax

```
CLZ{<c>}{<q>}  <Rd>, <Rm>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287.

`<Rd>` The destination register.

`<Rm>` The register that contains the operand. Its number must be encoded twice in encoding T1.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    result = CountLeadingZeroBits(R[m]);
    R[d] = result<31:0>;
```

Exceptions

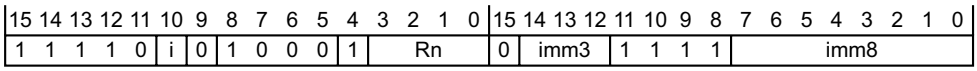
None.

A8.8.34 CMN (immediate)

Compare Negative (immediate) adds a register value and an immediate value. It updates the condition flags based on the result, and discards the result.

Encoding T1 ARMv6T2, ARMv7

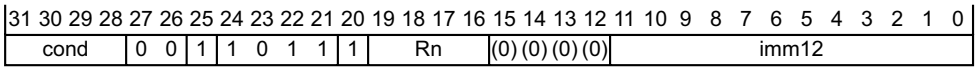
```
CMN<c> <Rn>, #<const>
```



```
n = UInt(Rn);  imm32 = ThumbExpandImm(i:imm3:imm8);
if n == 15 then UNPREDICTABLE;
```

Encoding A1 ARMv4*, ARMv5T*, ARMv6*, ARMv7

```
CMN<c> <Rn>, #<const>
```



```
n = UInt(Rn);  imm32 = ARMExpandImm(imm12);
```

Assembler syntax

```
CMN{<c>}{<q>}  <Rn>, #<const>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287.

`<Rn>` The register that contains the operand. SP can be used in Thumb and ARM instructions. The PC can be used in ARM instructions.

`<const>` The immediate value to be added to the value obtained from `<Rn>`. See *Modified immediate constants in Thumb instructions* on page A6-232 or *Modified immediate constants in ARM instructions* on page A5-200 for the range of values.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    (result, carry, overflow) = AddWithCarry(R[n], imm32, '0');
    APSR.N = result<31>;
    APSR.Z = IsZeroBit(result);
    APSR.C = carry;
    APSR.V = overflow;
```

Exceptions

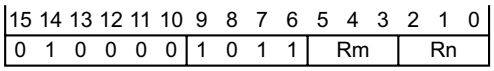
None.

A8.8.35 CMN (register)

Compare Negative (register) adds a register value and an optionally-shifted register value. It updates the condition flags based on the result, and discards the result.

Encoding T1 ARMv4T, ARMv5T*, ARMv6*, ARMv7

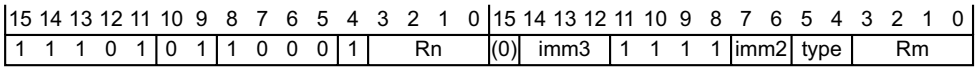
```
CMN<c> <Rn>, <Rm>
```



```
n = UInt(Rn);  m = UInt(Rm);
(shift_t, shift_n) = (SRType_LSL, 0);
```

Encoding T2 ARMv6T2, ARMv7

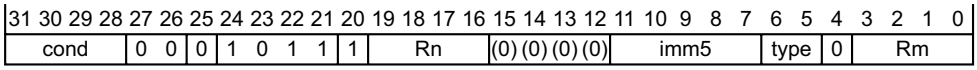
```
CMN<c>.W  <Rn>, <Rm>{, <shift>}
```



```
n = UInt(Rn);  m = UInt(Rm);
(shift_t, shift_n) = DecodeImmShift(type, imm3:imm2);
if n == 15 || m IN {13,15} then UNPREDICTABLE;
```

Encoding A1 ARMv4*, ARMv5T*, ARMv6*, ARMv7

```
CMN<c> <Rn>, <Rm>{, <shift>}
```



```
n = UInt(Rn);  m = UInt(Rm);
(shift_t, shift_n) = DecodeImmShift(type, imm5);
```

Assembler syntax

```
CMN{<c>}{<q>}  <Rn>, <Rm> {, <shift>}
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287.

`<Rn>` The first operand register. SP can be used in Thumb instructions (encoding T2) and in ARM instructions. The PC can be used in ARM instructions.

`<Rm>` The register that is optionally shifted and used as the second operand. The PC can be used in ARM instructions.

`<shift>` The shift to apply to the value read from `<Rm>`. If present, encoding T1 is not permitted. If absent, no shift is applied and all encodings are permitted. *Shifts applied to a register* on page A8-291 describes the shifts and how they are encoded.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shifted = Shift(R[m], shift_t, shift_n, APSR.C);
    (result, carry, overflow) = AddWithCarry(R[n], shifted, '0');
    APSR.N = result<31>;
    APSR.Z = IsZeroBit(result);
    APSR.C = carry;
    APSR.V = overflow;
```

Exceptions

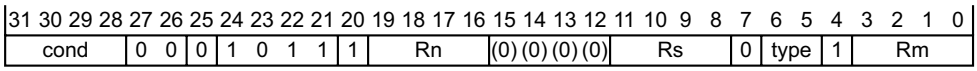
None.

A8.8.36 CMN (register-shifted register)

Compare Negative (register-shifted register) adds a register value and a register-shifted register value. It updates the condition flags based on the result, and discards the result.

Encoding A1 ARMv4*, ARMv5T*, ARMv6*, ARMv7

```
CMN<c> <Rn>, <Rm>, <type> <Rs>
```



31 30 29 28	27 26	25	24 23 22 21	20	19 18 17 16	15 14 13 12	11 10 9 8	7	6 5	4	3 2 1 0
cond	0 0	0	1 0 1 1	1	Rn	(0) (0) (0) (0)	Rs	0	type	1	Rm

```
n = UInt(Rn);  m = UInt(Rm);  s = UInt(Rs);
shift_t = DecodeRegShift(type);
if n == 15 || m == 15 || s == 15 then UNPREDICTABLE;
```

Assembler syntax

```
CMN{<c>}{<q>}  <Rn>, <Rm>, <type>  <Rs>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287.

`<Rn>` The first operand register.

`<Rm>` The register that is shifted and used as the second operand.

`<type>` The type of shift to apply to the value read from `<Rm>`. It must be one of:

- `ASR` Arithmetic shift right, encoded as type = `0b10`.
- `LSL` Logical shift left, encoded as type = `0b00`.
- `LSR` Logical shift right, encoded as type = `0b01`.
- `ROR` Rotate right, encoded as type = `0b11`.

`<Rs>` The register whose bottom byte contains the amount to shift by.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shift_n = UInt(R[s]<7:0>);
    shifted = Shift(R[m], shift_t, shift_n, APSR.C);
    (result, carry, overflow) = AddWithCarry(R[n], shifted, '0');
    APSR.N = result<31>;
    APSR.Z = IsZeroBit(result);
    APSR.C = carry;
    APSR.V = overflow;
```

Exceptions

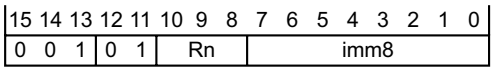
None.

A8.8.37 CMP (immediate)

Compare (immediate) subtracts an immediate value from a register value. It updates the condition flags based on the result, and discards the result.

Encoding T1 ARMv4T, ARMv5T*, ARMv6*, ARMv7

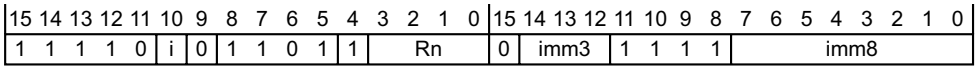
```
CMP<c> <Rn>, #<imm8>
```



```
n = UInt(Rn);  imm32 = ZeroExtend(imm8, 32);
```

Encoding T2 ARMv6T2, ARMv7

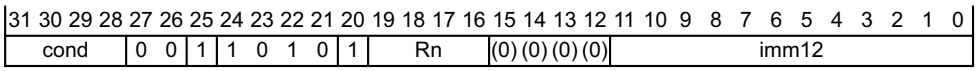
```
CMP<c>.W <Rn>, #<const>
```



```
n = UInt(Rn);  imm32 = ThumbExpandImm(i:imm3:imm8);
if n == 15 then UNPREDICTABLE;
```

Encoding A1 ARMv4*, ARMv5T*, ARMv6*, ARMv7

```
CMP<c> <Rn>, #<const>
```



```
n = UInt(Rn);  imm32 = ARMExpandImm(imm12);
```

Assembler syntax

```
CMP{<c>}{<q>}  <Rn>, #<const>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287.

`<Rn>` The first operand register. SP can be used in Thumb instructions (encoding T2) and in ARM instructions. The PC can be used in ARM instructions.

`<const>` The immediate value to be compared with the value obtained from `<Rn>`. The range of values is 0-255 for encoding T1. See *Modified immediate constants in Thumb instructions* on page A6-232 or *Modified immediate constants in ARM instructions* on page A5-200 for the range of values for encoding T2 and A1.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    (result, carry, overflow) = AddWithCarry(R[n], NOT(imm32), '1');
    APSR.N = result<31>;
    APSR.Z = IsZeroBit(result);
    APSR.C = carry;
    APSR.V = overflow;
```

Exceptions

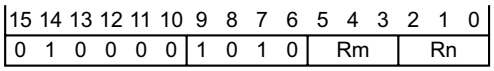
None.

A8.8.38 CMP (register)

Compare (register) subtracts an optionally-shifted register value from a register value. It updates the condition flags based on the result, and discards the result.

Encoding T1 ARMv4T, ARMv5T*, ARMv6*, ARMv7

`CMP<c> <Rn>, <Rm>` `<Rn>` and `<Rm>` both from R0-R7



15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	0	0	0	0	1	0	1	0	Rm			Rn

```
n = UInt(Rn);  m = UInt(Rm);
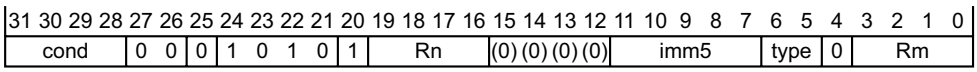
(shift_t, shift_n) = DecodeImmShift(type, imm3:imm2);
if n == 15 || m IN {13,15} then UNPREDICTABLE;
```

Encoding A1 ARMv4*, ARMv5T*, ARMv6*, ARMv7

`CMP<c> <Rn>, <Rm>{, <shift>}`



31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond				0	0	0	1	0	1	0	1	Rn				(0)	(0)	(0)	(0)	imm5					type		0	Rm			

```
n = UInt(Rn);  m = UInt(Rm);
(shift_t, shift_n) = DecodeImmShift(type, imm5);
```

Assembler syntax

```
CMP{<c>}{<q>}  <Rn>, <Rm> {, <shift>}
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287.

`<Rn>` The first operand register. The SP can be used. The PC can be used in ARM instructions.

`<Rm>` The register that is optionally shifted and used as the second operand. The PC can be used in ARM instructions.The SP can be used in both ARM and Thumb instructions, but:

- ARM deprecates the use of SP
- when assembling for the Thumb instruction set, only encoding T2 is available.

`<shift>` The shift to apply to the value read from `<Rm>`. If present, encodings T1 and T2 are not permitted. If absent, no shift is applied and all encodings are permitted. *Shifts applied to a register* on page A8-291 describes the shifts and how they are encoded.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shifted = Shift(R[m], shift_t, shift_n, APSR.C);
    (result, carry, overflow) = AddWithCarry(R[n], NOT(shifted), '1');
    APSR.N = result<31>;
    APSR.Z = IsZeroBit(result);
    APSR.C = carry;
    APSR.V = overflow;
```

Exceptions

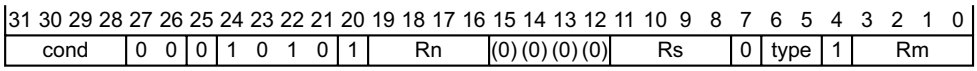
None.

A8.8.39 CMP (register-shifted register)

Compare (register-shifted register) subtracts a register-shifted register value from a register value. It updates the condition flags based on the result, and discards the result.

Encoding A1 ARMv4*, ARMv5T*, ARMv6*, ARMv7

```
CMP<c> <Rn>, <Rm>, <type> <Rs>
```



```
n = UInt(Rn);  m = UInt(Rm);  s = UInt(Rs);
shift_t = DecodeRegShift(type);
if n == 15 || m == 15 || s == 15 then UNPREDICTABLE;
```

Assembler syntax

```
CMP{<c>}{<q>}  <Rn>, <Rm>, <type>  <Rs>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287.

`<Rn>` The first operand register.

`<Rm>` The register that is shifted and used as the second operand.

`<type>` The type of shift to apply to the value read from `<Rm>`. It must be one of:

- `ASR` Arithmetic shift right, encoded as type = `0b10`.
- `LSL` Logical shift left, encoded as type = `0b00`.
- `LSR` Logical shift right, encoded as type = `0b01`.
- `ROR` Rotate right, encoded as type = `0b11`.

`<Rs>` The register whose bottom byte contains the amount to shift by.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shift_n = UInt(R[s]<7:0>);
    shifted = Shift(R[m], shift_t, shift_n, APSR.C);
    (result, carry, overflow) = AddWithCarry(R[n], NOT(shifted), '1');
    APSR.N = result<31>;
    APSR.Z = IsZeroBit(result);
    APSR.C = carry;
    APSR.V = overflow;
```

Exceptions

None.

A8.8.40 CPS

Change Processor State is a system instruction, see *CPS (Thumb)* on page B9-1976 and *CPS (ARM)* on page B9-1978.

A8.8.41 CPY

Copy is a pre-UAL synonym for `MOV` (register).

Assembler syntax

```
CPY  <Rd>, <Rn>
```

This is equivalent to:

```
MOV  <Rd>, <Rn>
```

Exceptions

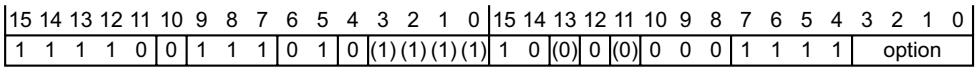
None.

A8.8.42 DBG

Debug Hint provides a hint to debug and related systems. See their documentation for what use (if any) they make of this instruction.

Encoding T1 ARMv7 (executes as NOP in ARMv6T2)

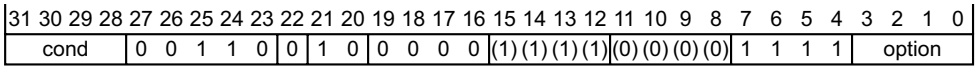
```
DBG<c> #<option>
```



```
// Any decoding of 'option' is specified by the debug system
```

Encoding A1 ARMv7 (executes as NOP in ARMv6Kand ARMv6T2)

```
DBG<c> #<option>
```



```
// Any decoding of 'option' is specified by the debug system
```

Assembler syntax

```
DBG{<c>}{<q>}  #<option>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287.

`<option>` Provides extra information about the hint, and is in the range 0 to 15.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    Hint_Debug(option);
```

Exceptions

None.

A8.8.43 DMB

Data Memory Barrier is a memory barrier that ensures the ordering of observations of memory accesses, see *Data Memory Barrier (DMB)* on page A3-151.

Encoding T1 ARMv7

```
DMB<c> <option>
```

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	0	0	1	1	1	0	1	1	(1)	(1)	(1)	(1)	1	0	(0)	0	(1)	(1)	(1)	(1)	0	1	0	1	option			

```
// No additional decoding required
```

Encoding A1 ARMv7

```
DMB <option>
```

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	0	1	0	1	0	1	1	1	(1)	(1)	(1)	(1)	(1)	(1)	(1)	(1)	(0)	(0)	(0)	(0)	0	1	0	1	option			

```
// No additional decoding required
```

Assembler syntax

```
DMB{<c>}{<q>}  {<option>}
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287. An ARM `DMB` instruction must be unconditional.

`<option>` Specifies an optional limitation on the DMB operation. Values are:

- `SY` Full system is the required shareability domain, reads and writes are the required access types. Can be omitted.
  This option is referred to as the full system DMB. Encoded as option = `0b1111`.
- `ST` Full system is the required shareability domain, writes are the required access type. `SYST` is a synonym for `ST`. Encoded as option = `0b1110`.
- `ISH` Inner Shareable is the required shareability domain, reads and writes are the required access types. Encoded as option = `0b1011`.
- `ISHST` Inner Shareable is the required shareability domain, writes are the required access type. Encoded as option = `0b1010`.
- `NSH` Non-shareable is the required shareability domain, reads and writes are the required access types. Encoded as option = `0b0111`.
- `NSHST` Non-shareable is the required shareability domain, writes are the required access type. Encoded as option = `0b0110`.
- `OSH` Outer Shareable is the required shareability domain, reads and writes are the required access types. Encoded as option = `0b0011`.
- `OSHST` Outer Shareable is the required shareability domain, writes are the required access type. Encoded as option = `0b0010`.

All other encodings of option are reserved. It is IMPLEMENTATION DEFINED whether options other than `SY` are implemented. All unsupported and reserved options must execute as a full system DMB operation, but software must not rely on this behavior.

Note

The instruction supports the following alternative <option> values, but ARM recommends that software does not use these alternative values:

- SH as an alias for ISH
- SHST as an alias for ISHST
- UN as an alias for NSH
- UNST is an alias for NSHST.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    case option of
        when '0010'  domain = MBReqDomain_OuterShareable;  types = MBReqTypes_Writes;
        when '0011'  domain = MBReqDomain_OuterShareable;  types = MBReqTypes_All;
        when '0110'  domain = MBReqDomain_Nonshareable;    types = MBReqTypes_Writes;
        when '0111'  domain = MBReqDomain_Nonshareable;    types = MBReqTypes_All;
        when '1010'  domain = MBReqDomain_InnerShareable;  types = MBReqTypes_Writes;
        when '1011'  domain = MBReqDomain_InnerShareable;  types = MBReqTypes_All;
        when '1110'  domain = MBReqDomain_FullSystem;      types = MBReqTypes_Writes;
        otherwise    domain = MBReqDomain_FullSystem;      types = MBReqTypes_All;
    if HaveVirtExt()  && !IsSecure() && !CurrentModeIsHyp() then
        if HCR.BSU == '11' then
            domain = MBReqDomain_FullSystem;
        if HCR.BSU == '10' && domain != MBReqDomain_FullSystem then
            domain = MBReqDomain_OuterShareable;
        if HCR.BSU == '01' && domain == MBReqDomain_Nonshareable then
            domain = MBReqDomain_InnerShareable;

    DataMemoryBarrier(domain, types);
```

Exceptions

None.

A8.8.44 DSB

Data Synchronization Barrier is a memory barrier that ensures the completion of memory accesses, see *Data Synchronization Barrier (DSB)* on page A3-152.

Encoding T1 ARMv7

```
DSB<c> <option>
```

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

```
// No additional decoding required
```

Assembler syntax

```
DSB{<c>}{<q>}  {<option>}
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287. An ARM `DSB` instruction must be unconditional.

`<option>` Specifies an optional limitation on the DSB operation. Values are:

- `SY` Full system is the required shareability domain, reads and writes are the required access types. Can be omitted.
  This option is referred to as the full system DSB. Encoded as option = `0b1111`.
- `ST` Full system is the required shareability domain, writes are the required access type. `SYST` is a synonym for `ST`. Encoded as option = `0b1110`.
- `ISH` Inner Shareable is the required shareability domain, reads and writes are the required access types. Encoded as option = `0b1011`.
- `ISHST` Inner Shareable is the required shareability domain, writes are the required access type. Encoded as option = `0b1010`.
- `NSH` Non-shareable is the required shareability domain, reads and writes are the required access types. Encoded as option = `0b0111`.
- `NSHST` Non-shareable is the required shareability domain, writes are the required access type. Encoded as option = `0b0110`.
- `OSH` Outer Shareable is the required shareability domain, reads and writes are the required access types. Encoded as option = `0b0011`.
- `OSHST` Outer Shareable is the required shareability domain, writes are the required access type. Encoded as option = `0b0010`.

All other encodings of option are reserved. It is IMPLEMENTATION DEFINED whether options other than `SY` are implemented. All unsupported and reserved options must execute as a full system DSB operation, but software must not rely on this behavior.

Note

The instruction supports the following alternative <option> values, but ARM recommends that software does not use these alternative values:

- SH as an alias for ISH
- SHST as an alias for ISHST
- UN as an alias for NSH
- UNST is an alias for NSHST.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    case option of
        when '0010'  domain = MBReqDomain_OuterShareable;  types = MBReqTypes_Writes;
        when '0011'  domain = MBReqDomain_OuterShareable;  types = MBReqTypes_All;
        when '0110'  domain = MBReqDomain_Nonshareable;    types = MBReqTypes_Writes;
        when '0111'  domain = MBReqDomain_Nonshareable;    types = MBReqTypes_All;
        when '1010'  domain = MBReqDomain_InnerShareable;  types = MBReqTypes_Writes;
        when '1011'  domain = MBReqDomain_InnerShareable;  types = MBReqTypes_All;
        when '1110'  domain = MBReqDomain_FullSystem;      types = MBReqTypes_Writes;
        otherwise    domain = MBReqDomain_FullSystem;      types = MBReqTypes_All;

    if HaveVirtExt() && !IsSecure() && !CurrentModeIsHyp()  then
        if HCR.BSU == '11' then
            domain = MBReqDomain_FullSystem;
        if HCR.BSU == '10' && domain != MBReqDomain_FullSystem then
            domain = MBReqDomain_OuterShareable;
        if HCR.BSU == '01' && domain == MBReqDomain_Nonshareable then
            domain = MBReqDomain_InnerShareable;

    DataSynchronizationBarrier(domain, types);
```

Exceptions

None.

A8.8.45 ENTERX

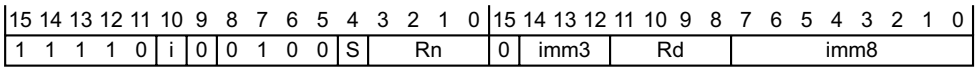
ENTERX causes a change from Thumb state to ThumbEE state, or has no effect in ThumbEE state. For details see *ENTERX, LEAVEX* on page A9-1116.

A8.8.46 EOR (immediate)

Bitwise Exclusive OR (immediate) performs a bitwise Exclusive OR of a register value and an immediate value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

Encoding T1 ARMv6T2, ARMv7

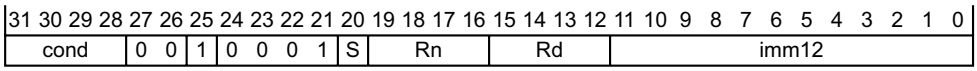
```
EOR{S}<c> <Rd>, <Rn>, #<const>
```



```
if Rd == '1111' && S == '1' then SEE TEQ (immediate);
d = UInt(Rd);  n = UInt(Rn);  setflags = (S == '1');
(imm32, carry) = ThumbExpandImm_C(i:imm3:imm8, APSR.C);
if d == 13 || (d == 15 && S == '0') || n IN {13,15} then UNPREDICTABLE;
```

Encoding A1 ARMv4*, ARMv5T*, ARMv6*, ARMv7

```
EOR{S}<c> <Rd>, <Rn>, #<const>
```



```
if Rd == '1111' && S == '1' then SEE SUBS PC, LR and related instructions;
d = UInt(Rd);  n = UInt(Rn);  setflags = (S == '1');
(imm32, carry) = ARMExpandImm_C(imm12, APSR.C);
```

Assembler syntax

```
EOR{S}{<c>}{<q>}  {<Rd>,} <Rn>, #<const>
```

where:

S — If S is present, the instruction updates the flags. Otherwise, the flags are not updated.

<c>, <q> — See *Standard assembler syntax fields* on page A8-287.

<Rd> — The destination register. If S is specified and <Rd> is the PC, see *SUBS PC, LR (Thumb)* on page B9-2008 or *SUBS PC, LR and related instructions (ARM)* on page B9-2010.

In ARM instructions, if S is not specified and <Rd> is the PC, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode details of operations on ARM core registers* on page A2-47.

Note

Before ARMv7, this was a simple branch.

<Rn> — The register that contains the operand. The PC can be used in ARM instructions.

<const> — The immediate value to be exclusive ORed with the value obtained from <Rn>. See *Modified immediate constants in Thumb instructions* on page A6-232 or *Modified immediate constants in ARM instructions* on page A5-200 for the range of values.

The pre-UAL syntax EOR<c>S is equivalent to EORS<c>.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    result = R[n] EOR imm32;
    if d == 15 then          // Can only occur for ARM encoding
        ALUWritePC(result);  // setflags is always FALSE here
    else
        R[d] = result;
        if setflags then
            APSR.N = result<31>;
            APSR.Z = IsZeroBit(result);
            APSR.C = carry;
            // APSR.V unchanged
```

Exceptions

None.

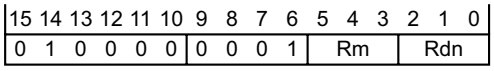
A8.8.47 EOR (register)

Bitwise Exclusive OR (register) performs a bitwise Exclusive OR of a register value and an optionally-shifted register value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

Encoding T1 ARMv4T, ARMv5T*, ARMv6*, ARMv7

`EORS <Rdn>, <Rm>` Outside IT block.

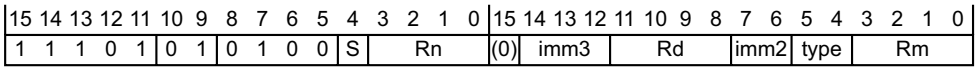
`EOR<c> <Rdn>, <Rm>` Inside IT block.



```
d = UInt(Rdn);  n = UInt(Rdn);  m = UInt(Rm);  setflags = !InITBlock();
(shift_t, shift_n) = (SRType_LSL, 0);
```

Encoding T2 ARMv6T2, ARMv7

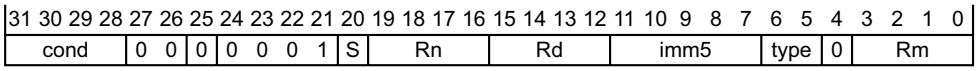
`EOR{S}<c>.W <Rd>, <Rn>, <Rm>{, <shift>}`



```
if Rd == '1111' && S == '1' then SEE TEQ (register);
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  setflags = (S == '1');
(shift_t, shift_n) = DecodeImmShift(type, imm3:imm2);
if d == 13 || (d == 15 && S == '0') || n IN {13,15} || m IN {13,15} then UNPREDICTABLE;
```

Encoding A1 ARMv4*, ARMv5T*, ARMv6*, ARMv7

`EOR{S}<c> <Rd>, <Rn>, <Rm>{, <shift>}`



```
if Rd == '1111' && S == '1' then SEE SUBS PC, LR and related instructions;
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  setflags = (S == '1');
(shift_t, shift_n) = DecodeImmShift(type, imm5);
```

Assembler syntax

```
EOR{S}{<c>}{<q>}  {<Rd>,} <Rn>, <Rm> {, <shift>}
```

where:

S — If S is present, the instruction updates the flags. Otherwise, the flags are not updated.

<c>, <q> — See *Standard assembler syntax fields* on page A8-287.

<Rd> — The destination register. If S is specified and <Rd> is the PC, see *SUBS PC, LR (Thumb)* on page B9-2008 or *SUBS PC, LR and related instructions (ARM)* on page B9-2010.

In ARM instructions, if S is not specified and <Rd> is the PC, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode details of operations on ARM core registers* on page A2-47.

Note

Before ARMv7, this was a simple branch.

<Rn> — The first operand register. The PC can be used in ARM instructions.

<Rm> — The register that is optionally shifted and used as the second operand. The PC can be used in ARM instructions.

<shift> — The shift to apply to the value read from <Rm>. If present, encoding T1 is not permitted. If absent, no shift is applied and all encodings are permitted.*Shifts applied to a register* on page A8-291 describes the shifts and how they are encoded.

In Thumb assembly:

- outside an IT block, if EORS <Rd>, <Rn>, <Rd> has <Rd> and <Rn> both in the range R0-R7, it is assembled using encoding T1 as though EORS <Rd>, <Rn> had been written
- inside an IT block, if EOR<c> <Rd>, <Rn>, <Rd> has <Rd> and <Rn> both in the range R0-R7, it is assembled using encoding T1 as though EOR<c> <Rd>, <Rn> had been written.

To prevent either of these happening, use the .W qualifier.

The pre-UAL syntax EOR<c>S is equivalent to EORS<c>.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    (shifted, carry) = Shift_C(R[m], shift_t, shift_n, APSR.C);
    result = R[n] EOR shifted;
    if d == 15 then          // Can only occur for ARM encoding
        ALUWritePC(result);  // setflags is always FALSE here
    else
        R[d] = result;
        if setflags then
            APSR.N = result<31>;
            APSR.Z = IsZeroBit(result);
            APSR.C = carry;
            // APSR.V unchanged
```

Exceptions

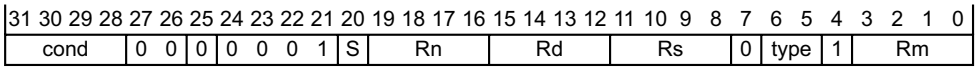
None.

A8.8.48 EOR (register-shifted register)

Bitwise Exclusive OR (register-shifted register) performs a bitwise Exclusive OR of a register value and a register-shifted register value. It writes the result to the destination register, and can optionally update the condition flags based on the result.

Encoding A1 ARMv4*, ARMv5T*, ARMv6*, ARMv7

```
EOR{S}<c> <Rd>, <Rn>, <Rm>, <type> <Rs>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  s = UInt(Rs);
setflags = (S == '1');  shift_t = DecodeRegShift(type);
if d == 15 || n == 15 || m == 15 || s == 15 then UNPREDICTABLE;
```

Assembler syntax

```
EOR{S}{<c>}{<q>}  {<Rd>,} <Rn>, <Rm>, <type>  <Rs>
```

where:

S — If S is present, the instruction updates the flags. Otherwise, the flags are not updated.

<c>, <q> — See *Standard assembler syntax fields* on page A8-287.

<Rd> — The destination register.

<Rn> — The first operand register.

<Rm> — The register that is shifted and used as the second operand.

<type> — The type of shift to apply to the value read from <Rm>. It must be one of:

- ASR — Arithmetic shift right, encoded as type = 0b10.
- LSL — Logical shift left, encoded as type = 0b00.
- LSR — Logical shift right, encoded as type = 0b01.
- ROR — Rotate right, encoded as type = 0b11.

<Rs> — The register whose bottom byte contains the amount to shift by.

The pre-UAL syntax EOR<c>S is equivalent to EORS<c>.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shift_n = UInt(R[s]<7:0>);
    (shifted, carry) = Shift_C(R[m], shift_t, shift_n, APSR.C);
    result = R[n] EOR shifted;
    R[d] = result;
    if setflags then
        APSR.N = result<31>;
        APSR.Z = IsZeroBit(result);
        APSR.C = carry;
        // APSR.V unchanged
```

Exceptions

None.

A8.8.49 ERET

Exception Return is a system instruction, see *ERET* on page B9-1980.

A8.8.50 F*, former Floating-point instruction mnemonics

Before the introduction of UAL, the Floating-point (VFP) instructions had mnemonics starting with `F`. In UAL, most of these mnemonics are renamed to start with `V`. *Other UAL mnemonic changes* on page AppxH-2469 lists all of the Floating-point instruction mnemonic changes. UAL does not define new mnemonics for the `FLDMX` and `FSTMX` instructions, see *FLDMX, FSTMX*.

FLDMX, FSTMX

Encodings T1/A1 of the `VLDM`, `VPOP`, `VPUSH`, and `VSTM` instructions contain an imm8 field that is set to twice the number of doubleword registers to be transferred. ARM deprecates use of these encodings with an odd value in imm8, and there is no UAL syntax for them.

The pre-UAL mnemonics `FLDMX` and `FSTMX` result in the same instructions as `FLDMD` (`VLDM.64` or `VPOP.64`) and `FSTMD` (`VSTM.64` or `VPUSH.64`) respectively, except that imm8 is equal to twice the number of doubleword registers plus one:

- from ARMv6, ARM deprecates use of `FLDMX` and `FSTMX`, except for disassembly purposes, and for reassembly of disassembled code
- if an `FLDMX` or `FSTMX` instruction accesses any register in the range D16-D32, the instruction is UNPREDICTABLE.

A8.8.51 HB, HBL, HBLP, HBP

These are ThumbEE instructions, see *HB, HBL* on page A9-1125, *HBLP* on page A9-1126, and *HBP* on page A9-1127.

A8.8.52 HVC

Hypervisor Call is a system instruction, see *HVC* on page B9-1982.

A8.8.53 ISB

Instruction Synchronization Barrier flushes the pipeline in the processor, so that all instructions following the `ISB` are fetched from cache or memory, after the instruction has been completed. It ensures that the effects of context changing operations executed before the `ISB` instruction are visible to the instructions fetched after the `ISB`. Context changing operations include changing the *Address Space Identifier* (ASID), TLB maintenance operations, branch predictor maintenance operations, and all changes to the CP15 registers. In addition, any branches that appear in program order after the `ISB` instruction are written into the branch prediction logic with the context that is visible after the `ISB` instruction. This is needed to ensure correct execution of the instruction stream.

Encoding T1 ARMv7

```
ISB<c> <option>
```

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	0	0	1	1	1	0	1	1	(1)	(1)	(1)	(1)	1	0	(0)	0	(1)	(1)	(1)	(1)	0	1	1	0	option			

```
// No additional decoding required
```

Encoding A1 ARMv7

```
ISB <option>
```

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	0	1	0	1	0	1	1	1	(1)	(1)	(1)	(1)	(1)	(1)	(1)	(1)	(0)	(0)	(0)	(0)	0	1	1	0	option			

```
// No additional decoding required
```

Assembler syntax

```
ISB{<c>}{<q>}  {<option>}
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287. An ARM `ISB` instruction must be unconditional.

`<option>` Specifies an optional limitation on the ISB operation. Values are:

`SY` Full system ISB operation, encoded as option = `0b1111`. Can be omitted.

All other encodings of option are reserved. The corresponding instructions execute as full system ISB operations, but must not be relied upon by software.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    InstructionSynchronizationBarrier();
```

Exceptions

None.

A8.8.54 IT

If-Then makes up to four following instructions (the *IT block*) conditional. The conditions for the instructions in the IT block are the same as, or the inverse of, the condition the IT instruction specifies for the first instruction in the block.

The IT instruction itself does not affect the condition flags, but the execution of the instructions in the IT block can change the condition flags.

16-bit instructions in the IT block, other than CMP, CMN and TST, do not set the condition flags. An IT instruction with the AL condition can be used to get this changed behavior without conditional execution.

The architecture permits exception return to an instruction in the IT block only if the restoration of the CPSR restores ITSTATE to a state consistent with the conditions specified by the IT instruction. Any other exception return to an instruction in an IT block is UNPREDICTABLE. Any branch to a target instruction in an IT block is not permitted, and if such a branch is made it is UNPREDICTABLE what condition is used when executing that target instruction and any subsequent instruction in the IT block.

See also *Conditional instructions* on page A4-162 and *Conditional execution* on page A8-288.

Encoding T1 ARMv6T2, ARMv7

`IT{<x>{<y>{<z>}}} <firstcond>` Not permitted in IT block

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	0	1	1	1	1	1	1	firstcond				mask			

```
if mask == '0000' then SEE "Related encodings";
if firstcond == '1111' || (firstcond == '1110' && BitCount(mask) != 1) then UNPREDICTABLE;
if InITBlock() then UNPREDICTABLE;
```

Related encodings See *If-Then, and hints* on page A6-229.

Assembler syntax

`IT{<x>{<y>{<z>}}}{<q>} <firstcond>`

where:

<x> The condition for the second instruction in the IT block.

<y> The condition for the third instruction in the IT block.

<z> The condition for the fourth instruction in the IT block.

<q> See *Standard assembler syntax fields* on page A8-287. An IT instruction must be unconditional.

<firstcond> The condition for the first instruction in the IT block. See Table A8-1 on page A8-288 for the range of conditions available, and the encodings.

Each of <x>, <y>, and <z> can be either:

T Then. The condition for the instruction is <firstcond>.

E Else. The condition for the instruction is the inverse of <firstcond>. The condition code is the same as <firstcond>, except that the least significant bit is inverted. E must not be specified if <firstcond> is AL.

Table A8-2 on page A8-391 shows how the values of <x>, <y>, and <z> determine the value of the mask field.

Table A8-2 Determination of mask field

<x>	<y>	<z>	mask[3]	mask[2]	mask[1]	mask[0]
Omitted	Omitted	Omitted	1	0	0	0
T	Omitted	Omitted	firstcond[0]	1	0	0
E	Omitted	Omitted	NOT firstcond[0]	1	0	0
T	T	Omitted	firstcond[0]	firstcond[0]	1	0
E	T	Omitted	NOT firstcond[0]	firstcond[0]	1	0
T	E	Omitted	firstcond[0]	NOT firstcond[0]	1	0
E	E	Omitted	NOT firstcond[0]	NOT firstcond[0]	1	0
T	T	T	firstcond[0]	firstcond[0]	firstcond[0]	1
E	T	T	NOT firstcond[0]	firstcond[0]	firstcond[0]	1
T	E	T	firstcond[0]	NOT firstcond[0]	firstcond[0]	1
E	E	T	NOT firstcond[0]	NOT firstcond[0]	firstcond[0]	1
T	T	E	firstcond[0]	firstcond[0]	NOT firstcond[0]	1
E	T	E	NOT firstcond[0]	firstcond[0]	NOT firstcond[0]	1
T	E	E	firstcond[0]	NOT firstcond[0]	NOT firstcond[0]	1
E	E	E	NOT firstcond[0]	NOT firstcond[0]	NOT firstcond[0]	1

The conditions specified in an IT instruction must match those specified in the syntax of the instructions in its IT block. When assembling to ARM code, assemblers check IT instruction syntax for validity but do not generate assembled instructions for them. See *Conditional instructions* on page A4-162.

Operation

```
EncodingSpecificOperations();
ITSTATE.IT<7:0> = firstcond:mask;
```

Exceptions

None.

A8.8.55 LDC, LDC2 (immediate)

Load Coprocessor loads memory data from a sequence of consecutive memory addresses to a coprocessor. If no coprocessor can execute the instruction, an Undefined Instruction exception is generated.

This is a generic coprocessor instruction. Some of the fields have no functionality defined by the architecture and are free for use by the coprocessor instruction set designer. These are the `D` bit, the `CRd` field, and in the Unindexed addressing mode only, the `imm8` field. However, coprocessors CP8-CP15 are reserved for use by ARM, and this manual defines the valid `LDC` and `LDC2` instructions when `coproc` is in the range `p8-p15`. For more information see *Coprocessor support* on page A2-94.

In an implementation that includes the Virtualization Extensions, the permitted `LDC` access to a system control register can be trapped to Hyp mode, meaning that an attempt to execute an `LDC` instruction in a Non-secure mode other than Hyp mode, that would be permitted in the absence of the Hyp trap controls, generates a Hyp Trap exception. For more information, see *Trapping general CP14 accesses to debug registers* on page B1-1260.

Note

For simplicity, the `LDC` pseudocode does not show this possible trap to Hyp mode.

`2` If specified, selects encoding T2/A2. If omitted, selects encoding T1/A1.

`L` If specified, selects the D == 1 form of the encoding. If omitted, selects the D == 0 form.

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287. An ARM `LDC2` instruction must be unconditional.

`<coproc>` The name of the coprocessor. The generic coprocessor names are p0-p15.

`<CRd>` The coprocessor destination register.

`<Rn>` The base register. The SP can be used. For PC use see *LDC, LDC2 (literal)* on page A8-394.

`+/-` Is + or omitted if the immediate offset is to be added to the base register value (`add == TRUE`, encoded as U ==1), or – if it is to be subtracted (`add == FALSE`, encoded as U==0). `#0` and `#-0` generate different instructions.

`<imm>` The immediate offset used for forming the address. Values are multiples of 4 in the range 0-1020. For the offset addressing syntax, `<imm>` can be omitted, meaning an offset of +0.

`<option>` A coprocessor option. An integer in the range 0-255 enclosed in { }. Encoded in imm8.

The pre-UAL syntax `LDC<c>L` is equivalent to `LDCL<c>`.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if !Coproc_Accepted(cp, ThisInstr()) then
        GenerateCoprocessorException();
    else
        NullCheckIfThumbEE(n);
        offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
        address = if index then offset_addr else R[n];
        repeat
            Coproc_SendLoadedWord(MemA[address,4], cp, ThisInstr());
            address = address + 4;
        until Coproc_DoneLoading(cp, ThisInstr());
        if wback then R[n] = offset_addr;
```

Exceptions

Undefined Instruction, Data Abort, Hyp Trap.

Uses of these instructions by specific coprocessors might generate other exceptions.

A8.8.56 LDC, LDC2 (literal)

Load Coprocessor loads memory data from a sequence of consecutive memory addresses to a coprocessor. If no coprocessor can execute the instruction, an Undefined Instruction exception is generated.

This is a generic coprocessor instruction. Some of the fields have no functionality defined by the architecture and are free for use by the coprocessor instruction set designer. These are the `D` bit, the `CRd` field, and in the Unindexed addressing mode only, the `imm8` field. However, coprocessors CP8-CP15 are reserved for use by ARM, and this manual defines the valid `LDC` and `LDC2` instructions when `coproc` is in the range `p8-p15`. For more information see *Coprocessor support* on page A2-94.

In an implementation that includes the Virtualization Extensions, the permitted `LDC` access to a system control register can be trapped to Hyp mode, meaning that an attempt to execute an `LDC` instruction in a Non-secure mode other than Hyp mode, that would be permitted in the absence of the Hyp trap controls, generates a Hyp Trap exception. For more information, see *Trapping general CP14 accesses to debug registers* on page B1-1260.

Note

For simplicity, the `LDC` pseudocode does not show this possible trap to Hyp mode.

Encoding T1/A1

ARMv6T2, ARMv7 for encoding T1

if W == '1' || (P == '0' && CurrentInstrSet() != InstrSet_ARM) then UNPREDICTABLE;
```

Advanced SIMD and Floating-point See *Extension register load/store instructions* on page A7-274

Assembler syntax

`LDC{2}{L}{<c>}{<q>} <coproc>, <CRd>, <label>`	Normal form with P = 1, W = 0
`LDC{2}{L}{<c>}{<q>} <coproc>, <CRd>, [PC, #+/-<imm>]`	Alternative form with P = 1, W = 0
`LDC{2}{L}{<c>}{<q>} <coproc>, <CRd>, [PC], <option>`	Unindexed form with P = 0, U = 1, W = 0, encoding A1/A2 only

where:

`2`	If specified, selects encoding T2/A2. If omitted, selects encoding T1/A1.
`L`	If specified, selects the D == 1 form of the encoding. If omitted, selects the D == 0 form.
`<c>, <q>`	See *Standard assembler syntax fields* on page A8-287. An ARM `LDC2` instruction must be unconditional.
`<coproc>`	The name of the coprocessor. The generic coprocessor names are p0-p15.
`<CRd>`	The coprocessor destination register.
`<label>`	The label of the literal data item that is to be loaded into `<Rt>`. The assembler calculates the required value of the offset from the `Align(PC, 4)` value of the instruction to this label. Permitted values of the offset are multiples of 4 in the range -1020 to 1020. If the offset is zero or positive, `imm32` is equal to the offset and `add == TRUE` (encoded as U == 1). If the offset is negative, `imm32` is equal to minus the offset and `add == FALSE` (encoded as U == 0).

The alternative syntax permits the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see *Use of labels in UAL instruction syntax* on page A4-162.

The unindexed form is permitted for the ARM instruction set only. In it, `<option>` is a coprocessor option, written as an integer 0-255 enclosed in { } and encoded in `imm8`.

The pre-UAL syntax `LDC<c>L` is equivalent to `LDCL<c>`.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if !Coproc_Accepted(cp, ThisInstr()) then
        GenerateCoprocessorException();
    else
        NullCheckIfThumbEE(15);
        offset_addr = if add then (Align(PC,4) + imm32) else (Align(PC,4) - imm32);
        address = if index then offset_addr else Align(PC,4);
        repeat
            Coproc_SendLoadedWord(MemA[address,4], cp, ThisInstr());
            address = address + 4;
        until Coproc_DoneLoading(cp, ThisInstr());
```

Exceptions

Undefined Instruction, Data Abort, Hyp Trap.

Uses of these instructions by specific coprocessors might generate other exceptions.

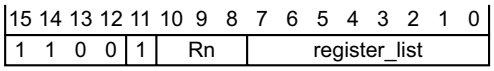
A8.8.57 LDM/LDMIA/LDMFD (Thumb)

Load Multiple Increment After (Load Multiple Full Descending) loads multiple registers from consecutive memory locations using an address from a base register. The consecutive memory locations start at this address, and the address just above the highest of those locations can optionally be written back to the base register. The registers loaded can include the PC, causing a branch to a loaded address. Related system instructions are *LDM (User registers)* on page B9-1986 and *LDM (exception return)* on page B9-1984.

Encoding T1 ARMv4T, ARMv5T*, ARMv6*, ARMv7 (not in ThumbEE)

`LDM<c> <Rn>!, <registers>` — `<Rn>` not included in `<registers>`

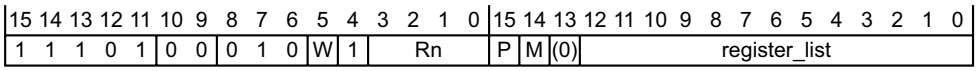
`LDM<c> <Rn>, <registers>` — `<Rn>` included in `<registers>`



```
if CurrentInstrSet() == InstrSet_ThumbEE then SEE "ThumbEE instructions";
n = UInt(Rn);  registers = '00000000':register_list;  wback = (registers<n> == '0');
if BitCount(registers) < 1 then UNPREDICTABLE;
```

Encoding T2 ARMv6T2, ARMv7

`LDM<c>.W <Rn>{!}, <registers>`



```
if W == '1' && Rn == '1101' then SEE POP (Thumb);
n = UInt(Rn);  registers = P:M:'0':register_list;  wback = (W == '1');
if n == 15 || BitCount(registers) < 2 || (P == '1' && M == '1') then UNPREDICTABLE;
if registers<15> == '1' && InITBlock() && !LastInITBlock() then UNPREDICTABLE;
if wback && registers<n> == '1' then UNPREDICTABLE;
```

ThumbEE instructions

See *16-bit ThumbEE instructions* on page A9-1115.

Assembler syntax

```
LDM{<c>}{<q>}  <Rn>{!}, <registers>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287.

`<Rn>` The base register. SP can be used. If it is the SP and ! is specified, the instruction is treated as described in *POP (Thumb)* on page A8-534.

`!` Causes the instruction to write a modified value back to `<Rn>`. Encoded as W = 1. If ! is omitted, the instruction does not change `<Rn>` in this way. Encoded as W = 0.

`<registers>` Is a list of one or more registers to be loaded, separated by commas and surrounded by { and }. The lowest-numbered register is loaded from the lowest memory address, through to the highest-numbered register from the highest memory address. See also *Encoding of lists of ARM core registers* on page A8-295.

Encoding T2 does not support a list containing only one register. If an `LDMIA` instruction with just one register `<Rt>` in the list is assembled to Thumb and encoding T1 is not available, it is assembled to the equivalent `LDR{<c>}{<q>} <Rt>, [<Rn>]{, #4}` instruction.

The SP cannot be in the list.

The PC can be in the list. If it is, the instruction branches to the address loaded to the PC. In ARMv5T and above, this is an interworking branch, see *Pseudocode details of operations on ARM core registers* on page A2-47. If the PC is in the list:

- the LR must not be in the list
- the instruction must be either outside any IT block, or the last instruction in an IT block.

If ! is specified, `<registers>` cannot include the base register.

`LDMIA` and `LDMFD` are pseudo-instructions for `LDM`. `LDMFD` refers to its use for popping data from Full Descending stacks.

The pre-UAL syntaxes `LDM<c>IA` and `LDM<c>FD` are equivalent to `LDM<c>`.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  NullCheckIfThumbEE(n);
    address = R[n];
    for i = 0 to 14
        if registers<i> == '1' then
            R[i] = MemA[address,4];  address = address + 4;
    if registers<15> == '1' then
        LoadWritePC(MemA[address,4]);
    if wback && registers<n> == '0' then R[n] = R[n] + 4*BitCount(registers);
    if wback && registers<n> == '1' then R[n] = bits(32) UNKNOWN;
```

Exceptions

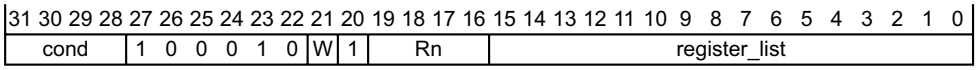
Data Abort.

A8.8.58 LDM/LDMIA/LDMFD (ARM)

Load Multiple Increment After (Load Multiple Full Descending) loads multiple registers from consecutive memory locations using an address from a base register. The consecutive memory locations start at this address, and the address just above the highest of those locations can optionally be written back to the base register. The registers loaded can include the PC, causing a branch to a loaded address. Related system instructions are *LDM (User registers)* on page B9-1986 and *LDM (exception return)* on page B9-1984.

Encoding A1 ARMv4*, ARMv5T*, ARMv6*, ARMv7

```
LDM<c> <Rn>{!}, <registers>
```



```
if W == '1' && Rn == '1101' && BitCount(register_list) > 1 then SEE POP (ARM);
n = UInt(Rn);  registers = register_list;  wback = (W == '1');
if n == 15 || BitCount(registers) < 1 then UNPREDICTABLE;
if wback && registers<n> == '1' && ArchVersion() >= 7 then UNPREDICTABLE;
```

Assembler syntax

```
LDM{<c>}{<q>}  <Rn>{!}, <registers>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287.

`<Rn>` The base register. SP can be used. If the SP is used, ! is specified, and there is more than one register in the `<registers>` list, the instruction is treated as described in *POP (ARM)* on page A8-536.

`!` Causes the instruction to write a modified value back to `<Rn>`. Encoded as W = 1. If ! is omitted, the instruction does not change `<Rn>` in this way. Encoded as W = 0.

`<registers>` Is a list of one or more registers to be loaded, separated by commas and surrounded by { and }. The lowest-numbered register is loaded from the lowest memory address, through to the highest-numbered register from the highest memory address. See also *Encoding of lists of ARM core registers* on page A8-295.

The SP can be in the list. However, ARM deprecates using these instructions with SP in the list.

The PC can be in the list. If it is, the instruction branches to the address loaded to the PC. In ARMv5T and above, this is an interworking branch, see *Pseudocode details of operations on ARM core registers* on page A2-47.

ARM deprecates using these instructions with both the LR and the PC in the list.

Instructions with the base register in the list and ! specified are only available before ARMv7, and ARM deprecates the use of such instructions. The value of the base register after such an instruction is UNKNOWN.

`LDMIA` and `LDMFD` are pseudo-instructions for `LDM`. `LDMFD` refers to its use for popping data from Full Descending stacks.

The pre-UAL syntaxes `LDM<c>IA` and `LDM<c>FD` are equivalent to `LDM<c>`.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  NullCheckIfThumbEE(n);
    address = R[n];

    if wback && registers<n> == '0' then R[n] = R[n] - 4*BitCount(registers);
    if wback && registers<n> == '1' then R[n] = bits(32) UNKNOWN;
```

Exceptions

Data Abort.

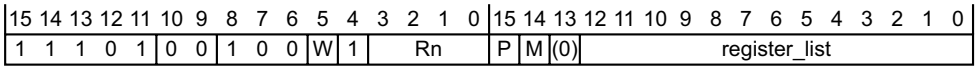
A8.8.60 LDMDB/LDMEA

Load Multiple Decrement Before (Load Multiple Empty Ascending) loads multiple registers from consecutive memory locations using an address from a base register. The consecutive memory locations end just below this address, and the address of the lowest of those locations can optionally be written back to the base register. The registers loaded can include the PC, causing a branch to a loaded address.

Related system instructions are *LDM (User registers)* on page B9-1986 and *LDM (exception return)* on page B9-1984.

Encoding T1 ARMv6T2, ARMv7

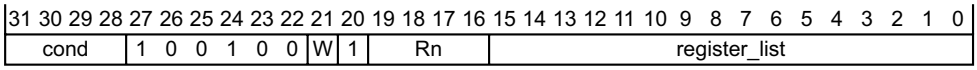
```
LDMDB<c> <Rn>{!}, <registers>
```



```
n = UInt(Rn);  registers = P:M:'0':register_list;  wback = (W == '1');
if n == 15 || BitCount(registers) < 2 || (P == '1' && M == '1') then UNPREDICTABLE;
if registers<15> == '1' && InITBlock() && !LastInITBlock() then UNPREDICTABLE;
if wback && registers<n> == '1' then UNPREDICTABLE;
```

Encoding A1 ARMv4*, ARMv5T*, ARMv6*, ARMv7

```
LDMDB<c> <Rn>{!}, <registers>
```



```
n = UInt(Rn);  registers = register_list;  wback = (W == '1');
if n == 15 || BitCount(registers) < 1 then UNPREDICTABLE;
if wback && registers<n> == '1' && ArchVersion() >= 7 then UNPREDICTABLE;
```

Assembler syntax

```
LDMDB{<c>}{<q>}  <Rn>{!}, <registers>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287.

`<Rn>` The base register. The SP can be used.

`!` Causes the instruction to write a modified value back to `<Rn>`. Encoded as W = 1.

If `!` is omitted, the instruction does not change `<Rn>` in this way. Encoded as W = 0.

`<registers>` Is a list of one or more registers to be loaded, separated by commas and surrounded by `{` and `}`. The lowest-numbered register is loaded from the lowest memory address, through to the highest-numbered register from the highest memory address. See also *Encoding of lists of ARM core registers* on page A8-295.

Encoding T1 does not support a list containing only one register. If an `LDMDB` instruction with just one register `<Rt>` in the list is assembled to Thumb, it is assembled to the equivalent `LDR{<c>}{<q>} <Rt>, [<Rn>, #-4]{!}` instruction.

The SP can be in the list in ARM instructions, but not in Thumb instructions. However, ARM instructions that include the SP in the list are deprecated.

The PC can be in the list. If it is, the instruction branches to the address loaded to the PC. In ARMv5T and above, this is an interworking branch, see *Pseudocode details of operations on ARM core registers* on page A2-47. In Thumb instructions, if the PC is in the list:

- the LR must not be in the list
- the instruction must be either outside any IT block, or the last instruction in an IT block.

ARM instructions that include both the LR and the PC in the list are deprecated.

Instructions with the base register in the list and ! specified are only available in the ARM instruction set before ARMv7, and ARM deprecates the use of such instructions. The value of the base register after such an instruction is UNKNOWN.

`LDMEA` is a pseudo-instruction for `LDMDB`, referring to its use for popping data from Empty Ascending stacks.

The pre-UAL syntaxes `LDM<c>DB` and `LDM<c>EA` are equivalent to `LDMDB<c>`.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  NullCheckIfThumbEE(n);
    address = R[n] - 4*BitCount(registers);
    for i = 0 to 14
        if registers<i> == '1' then
            R[i] = MemA[address,4];  address = address + 4;
    if registers<15> == '1' then
        LoadWritePC(MemA[address,4]);
    if wback && registers<n> == '0' then R[n] = R[n] - 4*BitCount(registers);
    if wback && registers<n> == '1' then R[n] = bits(32) UNKNOWN;
```

Exceptions

Data Abort.

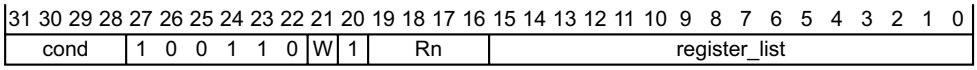
A8.8.61 LDMIB/LDMED

Load Multiple Increment Before (Load Multiple Empty Descending) loads multiple registers from consecutive memory locations using an address from a base register. The consecutive memory locations start just above this address, and the address of the last of those locations can optionally be written back to the base register. The registers loaded can include the PC, causing a branch to a loaded address.

Related system instructions are *LDM (User registers)* on page B9-1986 and *LDM (exception return)* on page B9-1984.

Encoding A1 ARMv4*, ARMv5T*, ARMv6*, ARMv7

```
LDMIB<c> <Rn>{!}, <registers>
```



```
n = UInt(Rn);  registers = register_list;  wback = (W == '1');
if n == 15 || BitCount(registers) < 1 then UNPREDICTABLE;

```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287.

`<Rn>` The base register. The SP can be used.

`!` Causes the instruction to write a modified value back to `<Rn>`. Encoded as W = 1.

If `!` is omitted, the instruction does not change `<Rn>` in this way. Encoded as W = 0.

`<registers>` Is a list of one or more registers to be loaded, separated by commas and surrounded by `{` and `}`. The lowest-numbered register is loaded from the lowest memory address, through to the highest-numbered register from the highest memory address. See also *Encoding of lists of ARM core registers* on page A8-295.

The SP can be in the list. However, instructions that include the SP in the list are deprecated.

The PC can be in the list. If it is, the instruction branches to the address (data) loaded to the PC. In ARMv5T and above, this branch is an interworking branch, see *Pseudocode details of operations on ARM core registers* on page A2-47.

Instructions that include both the LR and the PC in the list are deprecated.

Instructions with the base register in the list and ! specified are only available before ARMv7, and ARM deprecates the use of such instructions. The value of the base register after such an instruction is UNKNOWN.

`LDMED` is a pseudo-instruction for `LDMIB`, referring to its use for popping data from Empty Descending stacks.

The pre-UAL syntaxes `LDM<c>IB` and `LDM<c>ED` are equivalent to `LDMIB<c>`.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    address = R[n] + 4;
    for i = 0 to 14
        if registers<i> == '1' then
            R[i] = MemA[address,4];  address = address + 4;
    if registers<15> == '1' then
        LoadWritePC(MemA[address,4]);
    if wback && registers<n> == '0' then R[n] = R[n] + 4*BitCount(registers);
    if wback && registers<n> == '1' then R[n] = bits(32) UNKNOWN;
```

Exceptions

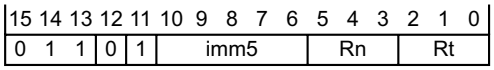
Data Abort.

A8.8.62 LDR (immediate, Thumb)

Load Register (immediate) calculates an address from a base register value and an immediate offset, loads a word from memory, and writes it to a register. It can use offset, post-indexed, or pre-indexed addressing. For information about memory accesses see *Memory accesses* on page A8-294.

Encoding T1 ARMv4T, ARMv5T*, ARMv6*, ARMv7

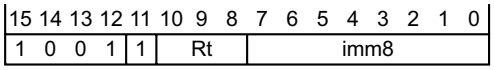
```
LDR<c> <Rt>, [<Rn>{, #<imm>}]
```



```
t = UInt(Rt);  n = UInt(Rn);  imm32 = ZeroExtend(imm5:'00', 32);
index = TRUE;  add = TRUE;  wback = FALSE;
```

Encoding T2 ARMv4T, ARMv5T*, ARMv6*, ARMv7

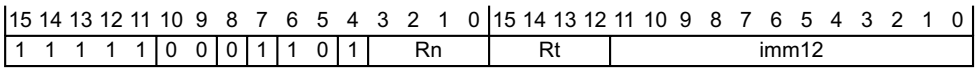
```
LDR<c> <Rt>, [SP{, #<imm>}]
```



```
t = UInt(Rt);  n = 13;  imm32 = ZeroExtend(imm8:'00', 32);
index = TRUE;  add = TRUE;  wback = FALSE;
```

Encoding T3 ARMv6T2, ARMv7

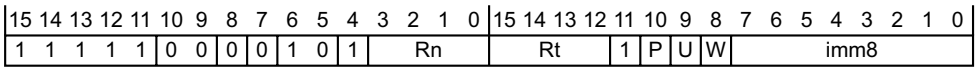
```
LDR<c>.W <Rt>, [<Rn>{, #<imm12>}]
```



```
if Rn == '1111' then SEE LDR (literal);
t = UInt(Rt);  n = UInt(Rn);  imm32 = ZeroExtend(imm12, 32); index = TRUE;  add = TRUE;
wback = FALSE; if t == 15 && InITBlock() && !LastInITBlock() then UNPREDICTABLE;
```

Encoding T4 ARMv6T2, ARMv7

```
LDR<c> <Rt>, [<Rn>, #-<imm8>]
LDR<c> <Rt>, [<Rn>], #+/-<imm8>
LDR<c> <Rt>, [<Rn>, #+/-<imm8>]!
```



```
if Rn == '1111' then SEE LDR (literal);
if P == '1' && U == '1' && W == '0' then SEE LDRT;
if Rn == '1101' && P == '0' && U == '1' && W == '1' && imm8 == '00000100' then SEE POP;
if P == '0' && W == '0' then UNDEFINED;
t = UInt(Rt);  n = UInt(Rn);
imm32 = ZeroExtend(imm8, 32); index = (P == '1');  add = (U == '1');  wback = (W == '1');
if (wback && n == t) || (t == 15 && InITBlock() && !LastInITBlock()) then UNPREDICTABLE;
```

Assembler syntax

`LDR{<c>}{<q>} <Rt>, [<Rn> {, #+/-<imm>}]`	Offset: `index==TRUE, wback==FALSE`
`LDR{<c>}{<q>} <Rt>, [<Rn>, #+/-<imm>]!`	Pre-indexed: `index==TRUE, wback==TRUE`
`LDR{<c>}{<q>} <Rt>, [<Rn>], #+/-<imm>`	Post-indexed: `index==FALSE, wback==TRUE`

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287.

`<Rt>` The destination register. The SP can be used. The PC can be used, provided the instruction is either outside an IT block or the last instruction of an IT block. If the PC is used, the instruction branches to the address (data) loaded to the PC. In ARMv5T and above, this branch is an interworking branch, see *Pseudocode details of operations on ARM core registers* on page A2-47.

`<Rn>` The base register. The SP can be used. For PC use see *LDR (literal)* on page A8-410.

`+/-`

`+` **or omitted** The immediate offset is to be added to the base register value (`add == TRUE`, encoded as U == 1 in encoding T4).

`-` The immediate offset is to be subtracted from the base register value. Encoding T4 must be used, with `add == FALSE`, encoded as U == 0.

`#0` and `#-0` generate different instructions.

`<imm>` The immediate offset used for forming the address. For the offset addressing syntax, `<imm>` can be omitted, meaning an offset of 0. Values are:

Encoding T1 Multiples of 4 in the range 0-124.

Encoding T2 Multiples of 4 in the range 0-1020.

Encoding T3 Any value in the range 0-4095.

Encoding T4 Any value in the range 0-255.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  NullCheckIfThumbEE(n);
    offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
    address = if index then offset_addr else R[n];
    data = MemU[address,4];
    if wback then R[n] = offset_addr;
    if t == 15 then
        if address<1:0> == '00' then LoadWritePC(data);  else UNPREDICTABLE;
    elsif UnalignedSupport() || address<1:0> == '00' then
        R[t] = data;
    else R[t] = bits(32) UNKNOWN; // Can only apply before ARMv7
```

Exceptions

Data Abort.

ThumbEE instruction

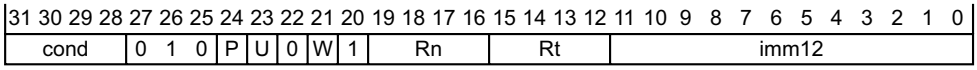
ThumbEE has additional `LDR` (immediate) encodings, see *LDR (immediate)* on page A9-1128.

A8.8.63 LDR (immediate, ARM)

Load Register (immediate) calculates an address from a base register value and an immediate offset, loads a word from memory, and writes it to a register. It can use offset, post-indexed, or pre-indexed addressing. For information about memory accesses see *Memory accesses* on page A8-294.

Encoding A1 ARMv4*, ARMv5T*, ARMv6*, ARMv7

```
LDR<c> <Rt>, [<Rn>{, #+/-<imm12>}]
LDR<c> <Rt>, [<Rn>], #+/-<imm12>
LDR<c> <Rt>, [<Rn>, #+/-<imm12>]!
```



```
if Rn == '1111' then SEE LDR (literal);
if P == '0' && W == '1' then SEE LDRT;
if Rn == '1101' && P == '0' && U == '1' && W == '0' && imm12 == '000000000100' then SEE POP;
t = UInt(Rt);  n = UInt(Rn);  imm32 = ZeroExtend(imm12, 32);
index = (P == '1');  add = (U == '1');  wback = (P == '0') || (W == '1');
if wback && n == t then UNPREDICTABLE;
```

Assembler syntax

`LDR{<c>}{<q>} <Rt>, [<Rn> {, #+/-<imm>}]`	Offset: `index==TRUE, wback==FALSE`
`LDR{<c>}{<q>} <Rt>, [<Rn>, #+/-<imm>]!`	Pre-indexed: `index==TRUE, wback==TRUE`
`LDR{<c>}{<q>} <Rt>, [<Rn>], #+/-<imm>`	Post-indexed: `index==FALSE, wback==TRUE`

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287.

`<Rt>` The destination register. The SP or the PC can be used. If the PC is used, the instruction branches to the address (data) loaded to the PC. In ARMv5T and above, this branch is an interworking branch, see *Pseudocode details of operations on ARM core registers* on page A2-47.

`<Rn>` The base register. The SP can be used. For PC use see *LDR (literal)* on page A8-410.

`+/-` Is + or omitted if the immediate offset is to be added to the base register value (`add == TRUE`, encoded as U ==1), or – if it is to be subtracted (`add == FALSE`, encoded as U ==0). `#0` and `#-0` generate different instructions.

`<imm>` The immediate offset used for forming the address. For the offset addressing syntax, `<imm>` can be omitted, meaning an offset of 0. Any value in the range 0-4095 is permitted.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
    address = if index then offset_addr else R[n];
    data = MemU[address,4];
    if wback then R[n] = offset_addr;
    if t == 15 then
        if address<1:0> == '00' then LoadWritePC(data);  else UNPREDICTABLE;
    elsif UnalignedSupport() || address<1:0> == '00' then
        R[t] = data;
    else // Can only apply before ARMv7
        R[t] = ROR(data, 8*UInt(address<1:0>));
```

Exceptions

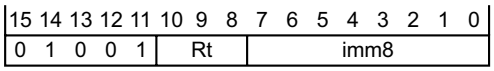
Data Abort.

A8.8.64 LDR (literal)

Load Register (literal) calculates an address from the PC value and an immediate offset, loads a word from memory, and writes it to a register. For information about memory accesses see *Memory accesses* on page A8-294.

Encoding T1 ARMv4T, ARMv5T*, ARMv6*, ARMv7

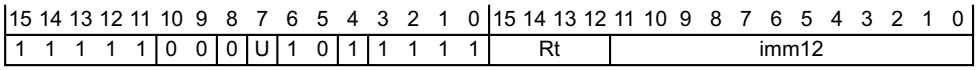
```
LDR<c> <Rt>, <label>
```



```
t = UInt(Rt);  imm32 = ZeroExtend(imm8:'00', 32);  add = TRUE;
```

Encoding T2 ARMv6T2, ARMv7

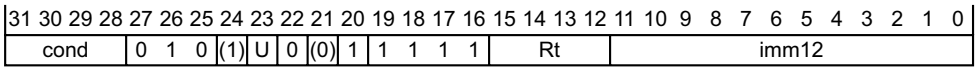
```
LDR<c>.W <Rt>, <label>
LDR<c>.W <Rt>, [PC, #-0]                                    Special case
```



```
t = UInt(Rt);  imm32 = ZeroExtend(imm12, 32);  add = (U == '1');
if t == 15 && InITBlock() && !LastInITBlock() then UNPREDICTABLE;
```

Encoding A1 ARMv4*, ARMv5T*, ARMv6*, ARMv7

```
LDR<c> <Rt>, <label>
LDR<c> <Rt>, [PC, #-0]                                      Special case
```



```
t = UInt(Rt);  imm32 = ZeroExtend(imm12, 32);  add = (U == '1');
```

Assembler syntax

`LDR{<c>}{<q>} <Rt>, <label>`	Normal form
`LDR{<c>}{<q>} <Rt>, [PC, #+/-<imm>]`	Alternative form

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287.

`<Rt>` The destination register. The SP can be used. The PC can be used, provided the instruction is either outside an IT block or the last instruction of an IT block. If the PC is used, the instruction branches to the address (data) loaded to the PC. In ARMv5T and above, this branch is an interworking branch, see *Pseudocode details of operations on ARM core registers* on page A2-47.

`<label>` The label of the literal data item that is to be loaded into `<Rt>`. The assembler calculates the required value of the offset from the `Align(PC, 4)` value of the instruction to this label. Permitted values of the offset are:

Encoding T1 Multiples of four in the range 0 to 1020.

Encoding T2 or A1 Any value in the range -4095 to 4095.

If the offset is zero or positive, `imm32` is equal to the offset and `add == TRUE`, encoded as U == 1 in encoding T2.

If the offset is negative, `imm32` is equal to minus the offset and `add == FALSE`, encoded as U == 0. Negative offset is not available in encoding T1.

Note

In examples in this manual, the syntax `=<value>` is used for the label of a memory word whose contents are constant and equal to `<value>`. The actual syntax for such a label is assembler-dependent.

The alternative syntax permits the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see *Use of labels in UAL instruction syntax* on page A4-162.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  NullCheckIfThumbEE(15);
    base = Align(PC,4);
    address = if add then (base + imm32) else (base - imm32);
    data = MemU[address,4];
    if t == 15 then
        if address<1:0> == '00' then LoadWritePC(data);  else UNPREDICTABLE;
    elsif UnalignedSupport() || address<1:0> == '00' then
        R[t] = data;
    else // Can only apply before ARMv7
        if CurrentInstrSet() == InstrSet_ARM then
            R[t] = ROR(data, 8*UInt(address<1:0>));
        else
            R[t] = bits(32) UNKNOWN;
```

Exceptions

Data Abort.

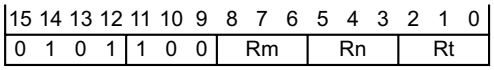
A8.8.65 LDR (register, Thumb)

Load Register (register) calculates an address from a base register value and an offset register value, loads a word from memory, and writes it to a register. The offset register value can optionally be shifted. For information about memory accesses, see *Memory accesses* on page A8-294.

The Thumb form of LDR (register) does not support register writeback.

Encoding T1 ARMv4T, ARMv5T*, ARMv6*, ARMv7

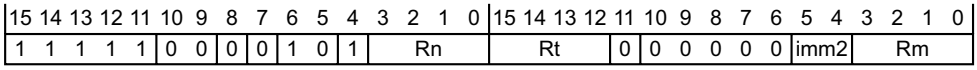
```
LDR<c> <Rt>, [<Rn>, <Rm>]
```



```
if CurrentInstrSet() == InstrSet_ThumbEE then SEE "Modified operation in ThumbEE";
t = UInt(Rt);  n = UInt(Rn);  m = UInt(Rm);
(shift_t, shift_n) = (SRType_LSL, 0);
```

Encoding T2 ARMv6T2, ARMv7

```
LDR<c>.W <Rt>, [<Rn>, <Rm>{, LSL #<imm2>}]
```



```
if Rn == '1111' then SEE LDR (literal);
t = UInt(Rt);  n = UInt(Rn);  m = UInt(Rm);
(shift_t, shift_n) = (SRType_LSL, UInt(imm2));
if m IN {13,15} then UNPREDICTABLE;
if t == 15 && InITBlock() && !LastInITBlock() then UNPREDICTABLE;
```

Modified operation in ThumbEE See *LDR (register)* on page A9-1118

Assembler syntax

`LDR{<c>}{<q>}  <Rt>, [<Rn>, {+}<Rm>{, <shift>}]` Offset addressing

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287.

`<Rt>` The destination register. The SP can be used. The PC can be used, provided the instruction is either outside an IT block or the last instruction of an IT block. If the PC is used, the instruction branches to the address (data) loaded to the PC. In ARMv5T and above, this branch is an interworking branch, see *Pseudocode details of operations on ARM core registers* on page A2-47.

`<Rn>` The base register. The SP can be used. In the Thumb instruction set, the PC cannot be used with this form of the `LDR` instruction.

`+` In Thumb instructions, the optionally shifted value of `<Rm>` is added to the base register value. Thumb instructions cannot subtract `<Rm>` from the base register value.

`<Rm>` The offset that is optionally shifted and applied to the value of `<Rn>` to form the address.

`<shift>` The shift to apply to the value read from `<Rm>`. If present, encoding T1 is not permitted. If absent, no shift is applied and all encodings are permitted. For encoding T2, `<shift>` can only be omitted, encoded as imm2 = `0b00`, or `LSL #<imm>` with `<imm>` = 1, 2, or 3, and `<imm>` encoded in imm2.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  NullCheckIfThumbEE(n);
    offset = Shift(R[m], shift_t, shift_n, APSR.C);
    offset_addr = (R[n] + offset);
    address = offset_addr;
    data = MemU[address,4];
    if t == 15 then
        if address<1:0> == '00' then
            LoadWritePC(data);
        else
            UNPREDICTABLE;
    elsif UnalignedSupport() || address<1:0> == '00' then
        R[t] = data;
    else // Can only apply before ARMv7
        R[t] = bits(32) UNKNOWN;
```

Exceptions

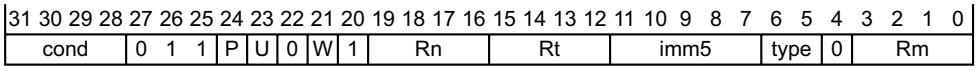
Data Abort.

A8.8.66 LDR (register, ARM)

Load Register (register) calculates an address from a base register value and an offset register value, loads a word from memory, and writes it to a register. The offset register value can optionally be shifted. For information about memory accesses, see *Memory accesses* on page A8-294.

Encoding A1 ARMv4*, ARMv5T*, ARMv6*, ARMv7

```
LDR<c> <Rt>, [<Rn>,+/-<Rm>{, <shift>}]{!}
LDR<c> <Rt>, [<Rn>],+/-<Rm>{, <shift>}
```



31 30 29 28	27 26 25	24	23	22	21	20	19 18 17 16	15 14 13 12	11 10 9 8 7	6 5	4	3 2 1 0
cond	0 1 1	P	U	0	W	1	Rn	Rt	imm5	type	0	Rm

```
if P == '0' && W == '1' then SEE LDRT;
t = UInt(Rt);  n = UInt(Rn);  m = UInt(Rm);
index = (P == '1');  add = (U == '1');  wback = (P == '0') || (W == '1');
(shift_t, shift_n) = DecodeImmShift(type, imm5);
if m == 15 then UNPREDICTABLE;
if wback && (n == 15 || n == t) then UNPREDICTABLE;
if ArchVersion() < 6 && wback && m == n then UNPREDICTABLE;
```

Assembler syntax

`LDR{<c>}{<q>} <Rt>, [<Rn>, {+/-}<Rm>{, <shift>}]`	Offset: `index==TRUE`, `wback==FALSE`
`LDR{<c>}{<q>} <Rt>, [<Rn>, {+/-}<Rm>{, <shift>}]!`	Pre-indexed: `index==TRUE`, `wback==TRUE`
`LDR{<c>}{<q>} <Rt>, [<Rn>], {+/-}<Rm>{, <shift>}`	Post-indexed: `index==FALSE`, `wback==TRUE`

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287.

`<Rt>` The destination register. The SP can be used. The PC can be used. If the PC is used, the instruction branches to the address (data) loaded to the PC. In ARMv5T and above, this branch is an interworking branch, see *Pseudocode details of operations on ARM core registers* on page A2-47.

`<Rn>` The base register. The SP can be used. The PC can be used for offset addressing only.

`+/-` If + or omitted, the optionally shifted value of `<Rm>` is added to the base register value (`add == TRUE` encoded as U == 1).

If –, the optionally shifted value of `<Rm>` is subtracted from the base register value (`add == FALSE` encoded as U == 0).

`<Rm>` The offset that is optionally shifted and applied to the value of `<Rn>` to form the address.

`<shift>` The shift to apply to the value read from `<Rm>`. If absent, no shift is applied. Otherwise, see *Shifts applied to a register* on page A8-291.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    offset = Shift(R[m], shift_t, shift_n, APSR.C);
    offset_addr = if add then (R[n] + offset) else (R[n] - offset);
    address = if index then offset_addr else R[n];
    data = MemU[address,4];
    if wback then R[n] = offset_addr;
    if t == 15 then
        if address<1:0> == '00' then
            LoadWritePC(data);
        else
            UNPREDICTABLE;
    elsif UnalignedSupport() || address<1:0> == '00' then
        R[t] = data;
    else // Can only apply before ARMv7
        R[t] = ROR(data, 8*UInt(address<1:0>));
```

Exceptions

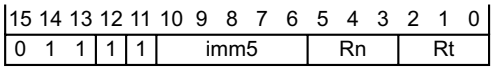
Data Abort.

A8.8.67 LDRB (immediate, Thumb)

Load Register Byte (immediate) calculates an address from a base register value and an immediate offset, loads a byte from memory, zero-extends it to form a 32-bit word, and writes it to a register. It can use offset, post-indexed, or pre-indexed addressing. For information about memory accesses see *Memory accesses* on page A8-294.

Encoding T1 ARMv4T, ARMv5T*, ARMv6*, ARMv7

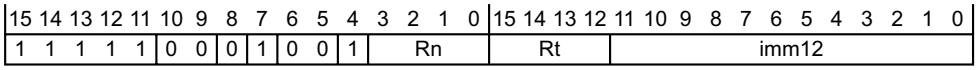
```
LDRB<c> <Rt>, [<Rn>{, #<imm5>}]
```



```
t = UInt(Rt);  n = UInt(Rn);  imm32 = ZeroExtend(imm5, 32);
index = TRUE;  add = TRUE;  wback = FALSE;
```

Encoding T2 ARMv6T2, ARMv7

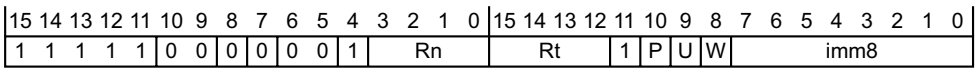
```
LDRB<c>.W <Rt>, [<Rn>{, #<imm12>}]
```



```
if Rt == '1111' then SEE PLD;
if Rn == '1111' then SEE LDRB (literal);
t = UInt(Rt);  n = UInt(Rn);  imm32 = ZeroExtend(imm12, 32);
index = TRUE;  add = TRUE;  wback = FALSE;
if t == 13 then UNPREDICTABLE;
```

Encoding T3 ARMv6T2, ARMv7

```
LDRB<c> <Rt>, [<Rn>, #-<imm8>]
LDRB<c> <Rt>, [<Rn>], #+/-<imm8>
LDRB<c> <Rt>, [<Rn>, #+/-<imm8>]!
```



```
if Rt == '1111' && P == '1' && U == '0' && W == '0' then SEE PLD, PLDW (immediate);
if Rn == '1111' then SEE LDRB (literal);
if P == '1' && U == '1' && W == '0' then SEE LDRBT;
if P == '0' && W == '0' then UNDEFINED;
t = UInt(Rt);  n = UInt(Rn);  imm32 = ZeroExtend(imm8, 32);
index = (P == '1');  add = (U == '1');  wback = (W == '1');

```

Assembler syntax

`LDRB{<c>}{<q>}  <Rt>, <label>`	Normal form
`LDRB{<c>}{<q>}  <Rt>, [PC, #+/-<imm>]`	Alternative form

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287.

`<Rt>` The destination register.

`<label>` The label of the literal data item that is to be loaded into `<Rt>`. The assembler calculates the required value of the offset from the `Align(PC, 4)` value of the instruction to this label. Permitted values of the offset are -4095 to 4095.

If the offset is zero or positive, `imm32` is equal to the offset and `add == TRUE`, encoded as U == 1.

If the offset is negative, `imm32` is equal to minus the offset and `add == FALSE`, encoded as U == 0.

The alternative syntax permits the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see *Use of labels in UAL instruction syntax* on page A4-162.

The pre-UAL syntax `LDR<c>B` is equivalent to `LDRB<c>`.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  NullCheckIfThumbEE(15);
    base = Align(PC,4);
    address = if add then (base + imm32) else (base - imm32);
    R[t] = ZeroExtend(MemU[address,1], 32);
```

Exceptions

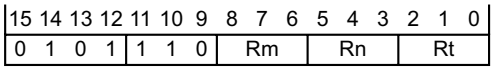
Data Abort.

A8.8.70 LDRB (register)

Load Register Byte (register) calculates an address from a base register value and an offset register value, loads a byte from memory, zero-extends it to form a 32-bit word, and writes it to a register. The offset register value can optionally be shifted. For information about memory accesses see *Memory accesses* on page A8-294.

Encoding T1 ARMv4T, ARMv5T*, ARMv6*, ARMv7

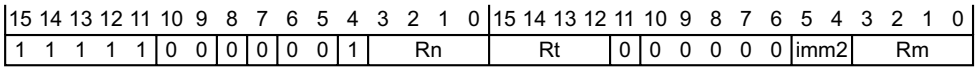
```
LDRB<c> <Rt>, [<Rn>, <Rm>]
```



```
t = UInt(Rt);  n = UInt(Rn);  m = UInt(Rm);
index = TRUE;  add = TRUE;  wback = FALSE;
(shift_t, shift_n) = (SRType_LSL, 0);
```

Encoding T2 ARMv6T2, ARMv7

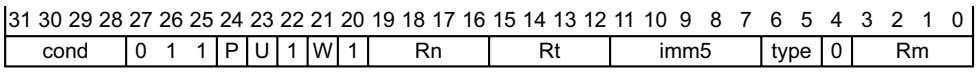
```
LDRB<c>.W <Rt>, [<Rn>, <Rm>{, LSL #<imm2>}]
```



```
if Rt == '1111' then SEE PLD;
if Rn == '1111' then SEE LDRB (literal);
t = UInt(Rt);  n = UInt(Rn);  m = UInt(Rm);
index = TRUE;  add = TRUE;  wback = FALSE;
(shift_t, shift_n) = (SRType_LSL, UInt(imm2));
if t == 13 || m IN {13,15} then UNPREDICTABLE;
```

Encoding A1 ARMv4*, ARMv5T*, ARMv6*, ARMv7

```
LDRB<c> <Rt>, [<Rn>,+/-<Rm>{, <shift>}]{!}
LDRB<c> <Rt>, [<Rn>],+/-<Rm>{, <shift>}
```



```
if P == '0' && W == '1' then SEE LDRBT;
t = UInt(Rt);  n = UInt(Rn);  m = UInt(Rm);
index = (P == '1');  add = (U == '1');  wback = (P == '0') || (W == '1');
(shift_t, shift_n) = DecodeImmShift(type, imm5);
if t == 15 || m == 15 then UNPREDICTABLE;
if wback && (n == 15 || n == t) then UNPREDICTABLE;
if ArchVersion() < 6 && wback && m == n then UNPREDICTABLE;
```

Assembler syntax

`LDRB{<c>}{<q>} <Rt>, [<Rn>, +/-<Rm>{, <shift>}]`	Offset: `index==TRUE, wback==FALSE`
`LDRB{<c>}{<q>} <Rt>, [<Rn>, +/-<Rm>{, <shift>}]!`	Pre-indexed: `index==TRUE, wback==TRUE`
`LDRB{<c>}{<q>} <Rt>, [<Rn>], +/-<Rm>{, <shift>}`	Post-indexed: `index==FALSE, wback==TRUE`

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287.

`<Rt>` The destination register.

`<Rn>` The base register. The SP can be used. In the ARM instruction set the PC can be used, for the offset addressing form of the instruction only. In the Thumb instruction set, the PC cannot be used with any of these forms of the `LDRB` instruction.

`+/-` Is + or omitted if the optionally shifted value of `<Rm>` is to be added to the base register value (`add == TRUE`, encoded as U == 1 in encoding A1), or – if it is to be subtracted (permitted in ARM instructions only, `add == FALSE`, encoded as U == 0).

`<Rm>` Contains the offset that is optionally shifted and applied to the value of `<Rn>` to form the address.

`<shift>` The shift to apply to the value read from `<Rm>`. If present, encoding T1 is not permitted. If absent, no shift is applied and all encodings are permitted. For encoding T2, `<shift>` can only be omitted, encoded as imm2 = `0b00`, or `LSL #<imm>` with `<imm>` = 1, 2, or 3, and `<imm>` encoded in imm2. For encoding A1, see *Shifts applied to a register* on page A8-291.

The pre-UAL syntax `LDR<c>B` is equivalent to `LDRB<c>`.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  NullCheckIfThumbEE(n);
    offset = Shift(R[m], shift_t, shift_n, APSR.C);
    offset_addr = if add then (R[n] + offset) else (R[n] - offset);
    address = if index then offset_addr else R[n];
    R[t] = ZeroExtend(MemU[address,1],32);
    if wback then R[n] = offset_addr;
```

Exceptions

Data Abort.

A8.8.71 LDRBT

Load Register Byte Unprivileged loads a byte from memory, zero-extends it to form a 32-bit word, and writes it to a register. For information about memory accesses see *Memory accesses* on page A8-294.

The memory access is restricted as if the processor were running in User mode. This makes no difference if the processor is actually running in User mode.

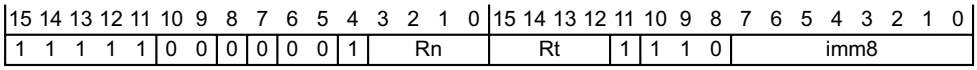
LDRBT is UNPREDICTABLE in Hyp mode.

The Thumb instruction uses an offset addressing mode, that calculates the address used for the memory access from a base register value and an immediate offset, and leaves the base register unchanged.

The ARM instruction uses a post-indexed addressing mode, that uses a base register value as the address for the memory access, and calculates a new address from a base register value and an offset and writes it back to the base register. The offset can be an immediate value or an optionally-shifted register value.

Encoding T1 ARMv6T2, ARMv7

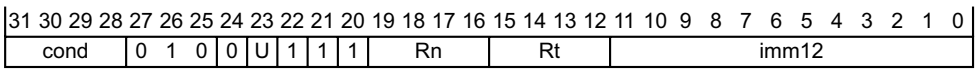
```
LDRBT<c> <Rt>, [<Rn>, #<imm8>]
```



```
if Rn == '1111' then SEE LDRB (literal);
t = UInt(Rt);  n = UInt(Rn);  postindex = FALSE;  add = TRUE;
register_form = FALSE;  imm32 = ZeroExtend(imm8, 32);
if t IN {13,15} then UNPREDICTABLE;
```

Encoding A1 ARMv4*, ARMv5T*, ARMv6*, ARMv7

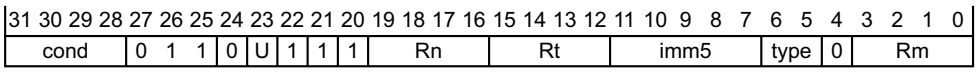
```
LDRBT<c> <Rt>, [<Rn>], #+/-<imm12>
```



```
t = UInt(Rt);  n = UInt(Rn);  postindex = TRUE;  add = (U == '1');
register_form = FALSE;  imm32 = ZeroExtend(imm12, 32);
if t == 15 || n == 15 || n == t then UNPREDICTABLE;
```

Encoding A2 ARMv4*, ARMv5T*, ARMv6*, ARMv7

```
LDRBT<c> <Rt>, [<Rn>],+/-<Rm>{, <shift>}
```



```
t = UInt(Rt);  n = UInt(Rn);  m = UInt(Rm);  postindex = TRUE;  add = (U == '1');
register_form = TRUE;  (shift_t, shift_n) = DecodeImmShift(type, imm5);
if t == 15 || n == 15 || n == t || m == 15 then UNPREDICTABLE;
if ArchVersion() < 6 && m == n then UNPREDICTABLE;
```

Assembler syntax

`LDRBT{<c>}{<q>}  <Rt>, [<Rn> {, #<imm>}]`	Offset: Thumb only
`LDRBT{<c>}{<q>}  <Rt>, [<Rn>] {, #+/-<imm>}`	Post-indexed: ARM only
`LDRBT{<c>}{<q>}  <Rt>, [<Rn>], +/-<Rm> {, <shift>}`	Post-indexed: ARM only

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287.

`<Rt>` The destination register.

`<Rn>` The base register. The SP can be used.

`+/-` Is + or omitted if `<imm>` or the optionally shifted value of `<Rm>` is to be added to the base register value (`add == TRUE`, encoded as U == 1 in encodings A1 and A2), or – if it is to be subtracted (permitted in ARM instructions only, `add == FALSE`, encoded as U == 0).

`<imm>` The immediate offset applied to the value of `<Rn>`. Values are 0-255 for encoding T1, and 0-4095 for encoding A1. `<imm>` can be omitted, meaning an offset of 0.

`<Rm>` Contains the offset that is optionally shifted and applied to the value of `<Rn>` to form the address.

`<shift>` The shift to apply to the value read from `<Rm>`. If omitted, no shift is applied. *Shifts applied to a register* on page A8-291 describes the shifts and how they are encoded.

The pre-UAL syntax `LDR<c>BT` is equivalent to `LDRBT<c>`.

Operation

```
if ConditionPassed() then
    if CurrentModeIsHyp() then UNPREDICTABLE;               // Hyp mode
    EncodingSpecificOperations();  NullCheckIfThumbEE(n);
    offset = if register_form then Shift(R[m], shift_t, shift_n, APSR.C) else imm32;
    offset_addr = if add then (R[n] + offset) else (R[n] - offset);
    address = if postindex then R[n] else offset_addr;
    R[t] = ZeroExtend(MemU_unpriv[address,1],32);
    if postindex then R[n] = offset_addr;
```

Exceptions

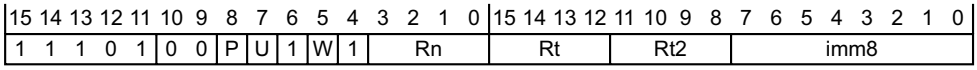
Data Abort.

A8.8.72 LDRD (immediate)

Load Register Dual (immediate) calculates an address from a base register value and an immediate offset, loads two words from memory, and writes them to two registers. It can use offset, post-indexed, or pre-indexed addressing. For information about memory accesses see *Memory accesses* on page A8-294.

Encoding T1 ARMv6T2, ARMv7

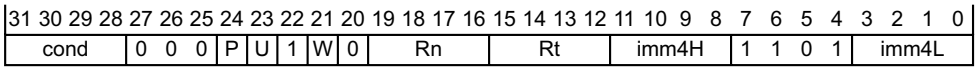
```
LDRD<c> <Rt>, <Rt2>, [<Rn>{, #+/-<imm>}]
LDRD<c> <Rt>, <Rt2>, [<Rn>], #+/-<imm>
LDRD<c> <Rt>, <Rt2>, [<Rn>, #+/-<imm>]!
```



```
if P == '0' && W == '0' then SEE "Related encodings";
if Rn == '1111' then SEE LDRD (literal);
t = UInt(Rt);  t2 = UInt(Rt2);  n = UInt(Rn);  imm32 = ZeroExtend(imm8:'00', 32);
index = (P == '1');  add = (U == '1');  wback = (W == '1');
if wback && (n == t || n == t2) then UNPREDICTABLE;
if t IN {13,15} || t2 IN {13,15} || t == t2 then UNPREDICTABLE;
```

Encoding A1 ARMv5TE*, ARMv6*, ARMv7

```
LDRD<c> <Rt>, <Rt2>, [<Rn>{, #+/-<imm8>}]
LDRD<c> <Rt>, <Rt2>, [<Rn>], #+/-<imm8>
LDRD<c> <Rt>, <Rt2>, [<Rn>, #+/-<imm8>]!
```



```
if Rn == '1111' then SEE LDRD (literal);
if Rt<0> == '1' then UNPREDICTABLE;
t = UInt(Rt);  t2 = t+1;  n = UInt(Rn);  imm32 = ZeroExtend(imm4H:imm4L, 32);
index = (P == '1');  add = (U == '1');  wback = (P == '0') || (W == '1');
if P == '0' && W == '1' then UNPREDICTABLE;
if wback && (n == t || n == t2) then UNPREDICTABLE;
if t2 == 15 then UNPREDICTABLE;
```

Related encodings See *Load/store dual, load/store exclusive, table branch* on page A6-238.

Assembler syntax

```
LDRD{<c>}{<q>}  <Rt>, <Rt2>, [<Rn> {, #+/-<imm>}]   Offset: index==TRUE, wback==FALSE
LDRD{<c>}{<q>}  <Rt>, <Rt2>, [<Rn>, #+/-<imm>]!     Pre-indexed: index==TRUE, wback==TRUE
LDRD{<c>}{<q>}  <Rt>, <Rt2>, [<Rn>], #+/-<imm>      Post-indexed: index==FALSE, wback==TRUE
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287.

`<Rt>` The first destination register. For an ARM instruction, `<Rt>` must be even-numbered and not R14.

`<Rt2>` The second destination register. For an ARM instruction, `<Rt2>` must be `<R(t+1)>`.

`<Rn>` The base register. The SP can be used. For PC use see *LDRD (literal)* on page A8-428.

`+/-` Is + or omitted if the immediate offset is to be added to the base register value (`add == TRUE`, encoded as U == 1), or – if it is to be subtracted (`add == FALSE`, encoded as U == 0). `#0` and `#-0` generate different instructions.

`<imm>` The immediate offset used for forming the address. For the offset addressing syntax, `<imm>` can be omitted, meaning an offset of 0. Values are:

Encoding T1 Multiples of 4 in the range 0-1020.

Encoding A1 Any value in the range 0-255.

The pre-UAL syntax `LDR<c>D` is equivalent to `LDRD<c>`.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  NullCheckIfThumbEE(n);
    offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
    address = if index then offset_addr else R[n];
    if HaveLPAE() && address<2:0> == '000' then
        data = MemA[address,8];
        if BigEndian()  then
            R[t] = data<63:32>;
            R[t2] = data<31:0>;
        else
            R[t] = data<31:0>;
            R[t2] = data<63:32>;
    else
        R[t] = MemA[address,4];
        R[t2] = MemA[address+4,4];
    if wback then R[n] = offset_addr;
```

Exceptions

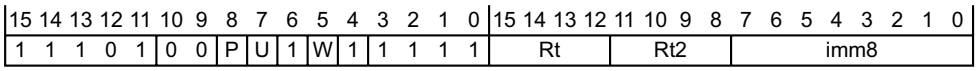
Data Abort.

A8.8.73 LDRD (literal)

Load Register Dual (literal) calculates an address from the PC value and an immediate offset, loads two words from memory, and writes them to two registers. For information about memory accesses see *Memory accesses* on page A8-294.

Encoding T1 ARMv6T2, ARMv7

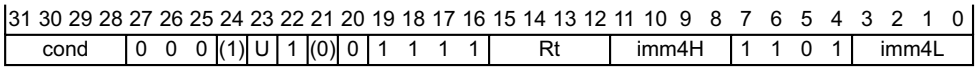
```
LDRD<c> <Rt>, <Rt2>, <label>
LDRD<c> <Rt>, <Rt2>, [PC, #-0]                    Special case
```



```
if P == '0' && W == '0' then SEE "Related encodings";
t = UInt(Rt);  t2 = UInt(Rt2);
imm32 = ZeroExtend(imm8:'00', 32);  add = (U == '1');
if t IN {13,15} || t2 IN {13,15} || t == t2 then UNPREDICTABLE;
if W == '1' then UNPREDICTABLE;
```

Encoding A1 ARMv5TE*, ARMv6*, ARMv7

```
LDRD<c> <Rt>, <Rt2>, <label>
LDRD<c> <Rt>, <Rt2>, [PC, #-0]                    Special case
```



```
if Rt<0> == '1' then UNPREDICTABLE;
t = UInt(Rt);  t2 = t+1;  imm32 = ZeroExtend(imm4H:imm4L, 32);  add = (U == '1');
if t2 == 15 then UNPREDICTABLE;
```

Related encodings See *Load/store dual, load/store exclusive, table branch* on page A6-238.

Assembler syntax

```
LDRD{<c>}{<q>}  <Rt>, <Rt2>, <label>                Normal form
LDRD{<c>}{<q>}  <Rt>, <Rt2>, [PC, #+/-<imm>]        Alternative form
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287.

`<Rt>` The first destination register. For an ARM instruction, `<Rt>` must be even-numbered and not R14.

`<Rt2>` The second destination register. For an ARM instruction, `<Rt2>` must be `<R(t+1)>`.

`<label>` The label of the literal data item that is to be loaded into `<Rt>`. The assembler calculates the required value of the offset from the `Align(PC, 4)` value of the instruction to this label. Permitted values of the offset are:

Encoding T1 Multiples of 4 in the range -1020 to 1020.

Encoding A1 Any value in the range -255 to 255.

If the offset is zero or positive, `imm32` is equal to the offset and `add == TRUE`, encoded as U == 1.

If the offset is negative, `imm32` is equal to minus the offset and `add == FALSE`, encoded as U == 0.

The alternative syntax permits the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see *Use of labels in UAL instruction syntax* on page A4-162.

The pre-UAL syntax `LDR<c>D` is equivalent to `LDRD<c>`.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  NullCheckIfThumbEE(15);
    address = if add then (Align(PC,4) + imm32) else (Align(PC,4) - imm32);
    if HaveLPAE() && address<2:0> == '000' then
        data = MemA[Address,8];
        if BigEndian() then
            R[t] = data<63:32>;
            R[t2] = data<31:0>;
        else
            R[t] = data<31:0>;
            R[t2] = data<63:32>;
    else
        R[t] = MemA[address,4];
        R[t2] = MemA[address+4,4];
```

Exceptions

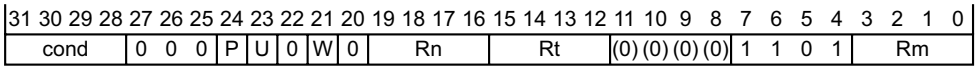
Data Abort.

A8.8.74 LDRD (register)

Load Register Dual (register) calculates an address from a base register value and a register offset, loads two words from memory, and writes them to two registers. It can use offset, post-indexed, or pre-indexed addressing. For information about memory accesses see *Memory accesses* on page A8-294.

Encoding A1 ARMv5TE*, ARMv6*, ARMv7

```
LDRD<c> <Rt>, <Rt2>, [<Rn>,+/-<Rm>]{!}
LDRD<c> <Rt>, <Rt2>, [<Rn>],+/-<Rm>
```



```
if Rt<0> == '1' then UNPREDICTABLE;

    address = R[n];
    SetExclusiveMonitors(address,8);
    value = MemA[address,8];
    // Extract words from 64-bit loaded value such that R[t] is
    // loaded from address and R[t2] from address+4.
    R[t]  = if BigEndian() then value<63:32> else value<31:0>;
    R[t2] = if BigEndian() then value<31:0> else value<63:32>;
```

Exceptions

Data Abort.

A8.8.78 LDREXH

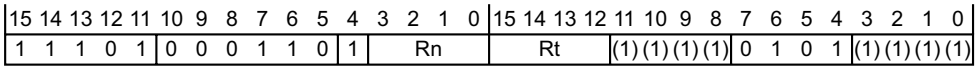
Load Register Exclusive Halfword derives an address from a base register value, loads a halfword from memory, zero-extends it to form a 32-bit word, writes it to a register and:

- if the address has the Shared Memory attribute, marks the physical address as exclusive access for the executing processor in a global monitor
- causes the executing processor to indicate an active exclusive access in the local monitor.

For more information about support for shared memory see *Synchronization and semaphores* on page A3-114. For information about memory accesses see *Memory accesses* on page A8-294.

Encoding T1 ARMv7

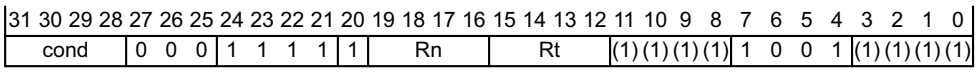
```
LDREXH<c> <Rt>, [<Rn>]
```



```
t = UInt(Rt);  n = UInt(Rn);
if t IN {13,15} || n == 15 then UNPREDICTABLE;
```

Encoding A1 ARMv6K, ARMv7

```
LDREXH<c> <Rt>, [<Rn>]
```



```
t = UInt(Rt);  n = UInt(Rn);
if t == 15 || n == 15 then UNPREDICTABLE;
```

Assembler syntax

```
LDREXH{<c>}{<q>}  <Rt>, [<Rn>]
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287.

`<Rt>` The destination register.

`<Rn>` The base register. The SP can be used.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  NullCheckIfThumbEE(n);
    address = R[n];
    SetExclusiveMonitors(address,2);
    R[t] = ZeroExtend(MemA[address,2], 32);
```

Exceptions

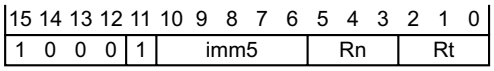
Data Abort.

A8.8.79 LDRH (immediate, Thumb)

Load Register Halfword (immediate) calculates an address from a base register value and an immediate offset, loads a halfword from memory, zero-extends it to form a 32-bit word, and writes it to a register. It can use offset, post-indexed, or pre-indexed addressing. For information about memory accesses see *Memory accesses* on page A8-294.

Encoding T1 ARMv4T, ARMv5T*, ARMv6*, ARMv7

```
LDRH<c> <Rt>, [<Rn>{, #<imm>}]
```



```
t = UInt(Rt);  n = UInt(Rn);  imm32 = ZeroExtend(imm5:'0', 32);
index = TRUE;  add = TRUE;  wback = FALSE;
```

Encoding T2 ARMv6T2, ARMv7

if P == '0' && W == '1' the SEE LDRHT;
if P == W then UNPREDICTABLE;
if t == 15 then UNPREDICTABLE;
```

Assembler syntax

`LDRH{<c>}{<q>}  <Rt>, <label>`	Normal form
`LDRH{<c>}{<q>}  <Rt>, [PC, #+/-<imm>]`	Alternative form

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287.

`<Rt>` The destination register.

`<label>` The label of the literal data item that is to be loaded into `<Rt>`. The assembler calculates the required value of the offset from the `Align(PC, 4)` value of the instruction to this label. Permitted values of the offset are:

Encoding T1 any value in the range -4095 to 4095

Encoding A1 any value in the range -255 to 255.

If the offset is zero or positive, `imm32` is equal to the offset and `add == TRUE`.

If the offset is negative, `imm32` is equal to minus the offset and `add == FALSE`.

The alternative syntax permits the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see *Use of labels in UAL instruction syntax* on page A4-162.

The pre-UAL syntax `LDR<c>H` is equivalent to `LDRH<c>`.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  NullCheckIfThumbEE(15);
    base = Align(PC,4);
    address = if add then (base + imm32) else (base - imm32);
    data = MemU[address,2];
    if UnalignedSupport() || address<0> == '0' then
        R[t] = ZeroExtend(data, 32);
    else // Can only apply before ARMv7
        R[t] = bits(32) UNKNOWN;
```

Exceptions

Data Abort.

A8.8.82 LDRH (register)

Load Register Halfword (register) calculates an address from a base register value and an offset register value, loads a halfword from memory, zero-extends it to form a 32-bit word, and writes it to a register. The offset register value can be shifted left by 0, 1, 2, or 3 bits. For information about memory accesses see *Memory accesses* on page A8-294.

Encoding T1 ARMv4T, ARMv5T*, ARMv6*, ARMv7

```

Modified operation in ThumbEE See *LDRH (register)* on page A9-1119

Assembler syntax

`LDRH{<c>}{<q>}  <Rt>, [<Rn>, <Rm>{, LSL #<imm>}]`	Offset: `index==TRUE`, `wback==FALSE`
`LDRH{<c>}{<q>}  <Rt>, [<Rn>, +/-<Rm>]`	Offset: `index==TRUE`, `wback==FALSE`
`LDRH{<c>}{<q>}  <Rt>, [<Rn>, +/-<Rm>]!`	Pre-indexed: `index==TRUE`, `wback==TRUE`
`LDRH{<c>}{<q>}  <Rt>, [<Rn>], +/-<Rm>`	Post-indexed: `index==FALSE`, `wback==TRUE`

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287.

`<Rt>` The destination register.

`<Rn>` The base register. The SP can be used. In the ARM instruction set the PC can be used, for offset addressing forms of the instruction only. In the Thumb instruction set, the PC cannot be used for any of these forms of the `LDRH` instruction.

`+/-` Is + or omitted if the optionally shifted value of `<Rm>` is to be added to the base register value (`add == TRUE`), or – if it is to be subtracted (permitted in ARM instructions only, `add == FALSE`).

`<Rm>` Contains the offset that is optionally left shifted and added to the value of `<Rn>` to form the address.

`<imm>` If present, the size of the left shift to apply to the value from `<Rm>`, in the range 1-3. Only encoding T2 is permitted, and `<imm>` is encoded in imm2.

If absent, no shift is specified and all encodings are permitted. In encoding T2, imm2 is encoded as `0b00`.

The pre-UAL syntax `LDR<c>H` is equivalent to `LDRH<c>`.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  NullCheckIfThumbEE(n);
    offset = Shift(R[m], shift_t, shift_n, APSR.C);
    offset_addr = if add then (R[n] + offset) else (R[n] - offset);
    address = if index then offset_addr else R[n];
    data = MemU[address,2];
    if wback then R[n] = offset_addr;
    if UnalignedSupport() || address<0> == '0' then
        R[t] = ZeroExtend(data, 32);
    else // Can only apply before ARMv7
        R[t] = bits(32) UNKNOWN;
```

Exceptions

Data Abort.

A8.8.83 LDRHT

Load Register Halfword Unprivileged loads a halfword from memory, zero-extends it to form a 32-bit word, and writes it to a register. For information about memory accesses see *Memory accesses* on page A8-294.

The memory access is restricted as if the processor were running in User mode. This makes no difference if the processor is actually running in User mode.

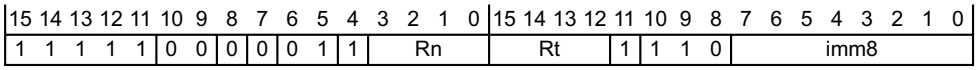
LDRHT is UNPREDICTABLE in Hyp mode.

The Thumb instruction uses an offset addressing mode, that calculates the address used for the memory access from a base register value and an immediate offset, and leaves the base register unchanged.

The ARM instruction uses a post-indexed addressing mode, that uses a base register value as the address for the memory access, and calculates a new address from a base register value and an offset and writes it back to the base register. The offset can be an immediate value or a register value.

Encoding T1 ARMv6T2, ARMv7

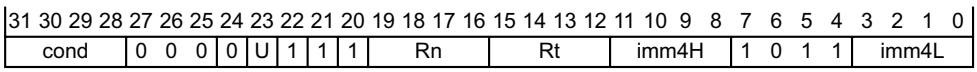
```
LDRHT<c> <Rt>, [<Rn>, #<imm8>]
```



```
if Rn == '1111' then SEE LDRH (literal);
t = UInt(Rt);  n = UInt(Rn);  postindex = FALSE;  add = TRUE;
register_form = FALSE;  imm32 = ZeroExtend(imm8, 32);
if t IN {13,15} then UNPREDICTABLE;
```

Encoding A1 ARMv6T2, ARMv7

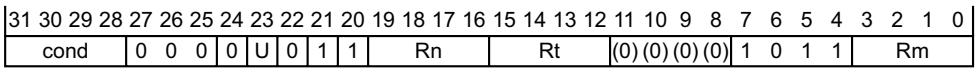
```
LDRHT<c> <Rt>, [<Rn>] {, #+/-<imm8>}
```



```
t = UInt(Rt);  n = UInt(Rn);  postindex = TRUE;  add = (U == '1');
register_form = FALSE;  imm32 = ZeroExtend(imm4H:imm4L, 32);
if t == 15 || n == 15 || n == t then UNPREDICTABLE;
```

Encoding A2 ARMv6T2, ARMv7

```
LDRHT<c> <Rt>, [<Rn>], +/-<Rm>
```



```
t = UInt(Rt);  n = UInt(Rn);  m = UInt(Rm);  postindex = TRUE;  add = (U == '1');
register_form = TRUE;
if t == 15 || n == 15 || n == t || m == 15 then UNPREDICTABLE;
```

Assembler syntax

`LDRHT{<c>}{<q>}  <Rt>, [<Rn> {, #<imm>}]`	Offset: Thumb only
`LDRHT{<c>}{<q>}  <Rt>, [<Rn>] {, #+/-<imm>}`	Post-indexed: ARM only
`LDRHT{<c>}{<q>}  <Rt>, [<Rn>], +/-<Rm>`	Post-indexed: ARM only

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287.

`<Rt>` The destination register.

`<Rn>` The base register. The SP can be used.

`+/-` Is + or omitted if `<imm>` or the optionally shifted value of `<Rm>` is to be added to the base register value.Encoded as `add = TRUE`.

Is – if `<imm>` or the optionally shifted value of `<Rm>` is to be subtracted from the base register value. This is permitted in ARM instructions only, and is encoded as `add = FALSE`.

`<imm>` The immediate offset applied to the value of `<Rn>`. Any value in the range 0-255 is permitted. `<imm>` can be omitted, meaning an offset of 0.

`<Rm>` Contains the offset that is applied to the value of `<Rn>` to form the address.

Operation

```
if ConditionPassed() then
    if CurrentModeIsHyp() then UNPREDICTABLE;               // Hyp mode
    EncodingSpecificOperations();  NullCheckIfThumbEE(n);
    offset = if register_form then R[m] else imm32;
    offset_addr = if add then (R[n] + offset) else (R[n] - offset);
    address = if postindex then R[n] else offset_addr;
    data = MemU_unpriv[address,2];

    if wback then R[n] = offset_addr;
```

Exceptions

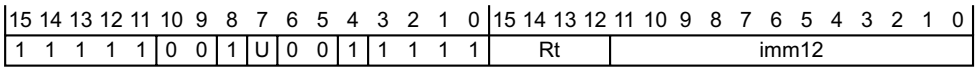
Data Abort.

A8.8.85 LDRSB (literal)

Load Register Signed Byte (literal) calculates an address from the PC value and an immediate offset, loads a byte from memory, sign-extends it to form a 32-bit word, and writes it to a register. For information about memory accesses see *Memory accesses* on page A8-294.

Encoding T1 ARMv6T2, ARMv7

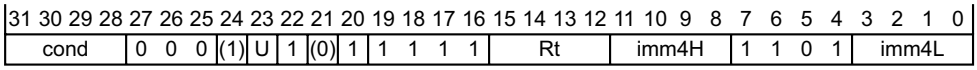
```
LDRSB<c> <Rt>, <label>
LDRSB<c> <Rt>, [PC, #-0]                                    Special case
```



```
if Rt == '1111' then SEE PLI;
t = UInt(Rt);  imm32 = ZeroExtend(imm12, 32);  add = (U == '1');
if t == 13 then UNPREDICTABLE;
```

Encoding A1 ARMv4*, ARMv5T*, ARMv6*, ARMv7

```
LDRSB<c> <Rt>, <label>
LDRSB<c> <Rt>, [PC, #-0]                                    Special case
```



```
t = UInt(Rt);  imm32 = ZeroExtend(imm4H:imm4L, 32);  add = (U == '1');
if t == 15 then UNPREDICTABLE;
```

Assembler syntax

`LDRSB{<c>}{<q>}  <Rt>, <label>`	Normal form
`LDRSB{<c>}{<q>}  <Rt>, [PC, #+/-<imm>]`	Alternative form

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287.

`<Rt>` The destination register.

`<label>` The label of the literal data item that is to be loaded into `<Rt>`. The assembler calculates the required value of the offset from the `Align(PC, 4)` value of the instruction to this label. Permitted values of the offset are:

Encoding T1 any value in the range -4095 to 4095

Encoding A1 any value in the range -255 to 255.

If the offset is zero or positive, `imm32` is equal to the offset and `add == TRUE`.

If the offset is negative, `imm32` is equal to minus the offset and `add == FALSE`.

The alternative syntax permits the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see *Use of labels in UAL instruction syntax* on page A4-162.

The pre-UAL syntax `LDR<c>SB` is equivalent to `LDRSB<c>`.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  NullCheckIfThumbEE(15);
    base = Align(PC,4);
    address = if add then (base + imm32) else (base - imm32);
    R[t] = SignExtend(MemU[address,1], 32);
```

Exceptions

Data Abort.

A8.8.86 LDRSB (register)

Load Register Signed Byte (register) calculates an address from a base register value and an offset register value, loads a byte from memory, sign-extends it to form a 32-bit word, and writes it to a register. The offset register value can be shifted left by 0, 1, 2, or 3 bits. For information about memory accesses see *Memory accesses* on page A8-294.

Encoding T1 ARMv4T, ARMv5T*, ARMv6*, ARMv7

```
LDRSB<c> <Rt>, [<Rn>, <Rm>]
```

```

Assembler syntax

`LDRSB{<c>}{<q>} <Rt>, [<Rn>, <Rm>{, LSL #<imm>}]`	Offset: `index==TRUE`, `wback==FALSE`
`LDRSB{<c>}{<q>} <Rt>, [<Rn>, +/-<Rm>]`	Offset: `index==TRUE`, `wback==FALSE`
`LDRSB{<c>}{<q>} <Rt>, [<Rn>, +/-<Rm>]!`	Pre-indexed: `index==TRUE`, `wback==TRUE`
`LDRSB{<c>}{<q>} <Rt>, [<Rn>], +/-<Rm>`	Post-indexed: `index==FALSE`, `wback==TRUE`

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287.

`<Rt>` The destination register.

`<Rn>` The base register. The SP can be used. In the ARM instruction set the PC can be used, for the offset addressing forms of the instruction only. In the Thumb instruction set, the PC cannot be used for any of these forms of the `LDRSB` instruction.

`+/-` Is + or omitted if the optionally shifted value of `<Rm>` is to be added to the base register value (`add == TRUE`), or – if it is to be subtracted (permitted in ARM instructions only, `add == FALSE`).

`<Rm>` Contains the offset that is optionally left shifted and added to the value of `<Rn>` to form the address.

`<imm>` If present, the size of the left shift to apply to the value from `<Rm>`, in the range 1-3. Only encoding T2 is permitted, and `<imm>` is encoded in imm2.

If absent, no shift is specified and all encodings are permitted. In encoding T2, imm2 is encoded as `0b00`.

The pre-UAL syntax `LDR<c>SB` is equivalent to `LDRSB<c>`.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  NullCheckIfThumbEE(n);
    offset = Shift(R[m], shift_t, shift_n, APSR.C);
    offset_addr = if add then (R[n] + offset) else (R[n] - offset);
    address = if index then offset_addr else R[n];
    R[t] = SignExtend(MemU[address,1], 32);
    if wback then R[n] = offset_addr;
```

Exceptions

Data Abort.

A8.8.87 LDRSBT

Load Register Signed Byte Unprivileged loads a byte from memory, sign-extends it to form a 32-bit word, and writes it to a register. For information about memory accesses see *Memory accesses* on page A8-294.

The memory access is restricted as if the processor were running in User mode. This makes no difference if the processor is actually running in User mode.

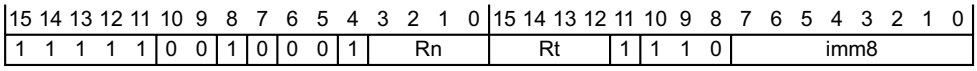
LDRSBT is UNPREDICTABLE in Hyp mode.

The Thumb instruction uses an offset addressing mode, that calculates the address used for the memory access from a base register value and an immediate offset, and leaves the base register unchanged.

The ARM instruction uses a post-indexed addressing mode, that uses a base register value as the address for the memory access, and calculates a new address from a base register value and an offset and writes it back to the base register. The offset can be an immediate value or a register value.

Encoding T1 ARMv6T2, ARMv7

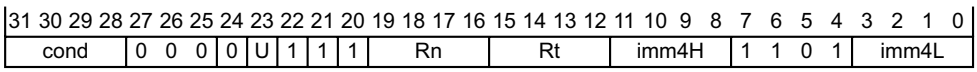
```
LDRSBT<c> <Rt>, [<Rn>, #<imm8>]
```



```
if Rn == '1111' then SEE LDRSB (literal);
t = UInt(Rt);  n = UInt(Rn);  postindex = FALSE;  add = TRUE;
register_form = FALSE;  imm32 = ZeroExtend(imm8, 32);
if t IN {13,15} then UNPREDICTABLE;
```

Encoding A1 ARMv6T2, ARMv7

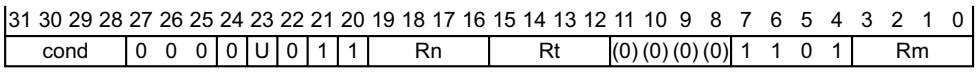
```
LDRSBT<c> <Rt>, [<Rn>] {, #+/-<imm8>}
```



```
t = UInt(Rt);  n = UInt(Rn);  postindex = TRUE;  add = (U == '1');
register_form = FALSE;  imm32 = ZeroExtend(imm4H:imm4L, 32);
if t == 15 || n == 15 || n == t then UNPREDICTABLE;
```

Encoding A2 ARMv6T2, ARMv7

```
LDRSBT<c> <Rt>, [<Rn>], +/-<Rm>
```



```
t = UInt(Rt);  n = UInt(Rn);  m = UInt(Rm);  postindex = TRUE;  add = (U == '1');
register_form = TRUE;
if t == 15 || n == 15 || n == t || m == 15 then UNPREDICTABLE;
```

Assembler syntax

`LDRSBT{<c>}{<q>}  <Rt>, [<Rn> {, #<imm>}]`	Offset: Thumb only
`LDRSBT{<c>}{<q>}  <Rt>, [<Rn>] {, #+/-<imm>}`	Post-indexed: ARM only
`LDRSBT{<c>}{<q>}  <Rt>, [<Rn>], +/-<Rm>`	Post-indexed: ARM only

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287.

`<Rt>` The destination register.

`<Rn>` The base register. The SP can be used.

`+/-` Is + or omitted if `<imm>` or the optionally shifted value of `<Rm>` is to be added to the base register value (`add == TRUE`), or – if it is to be subtracted (permitted in ARM instructions only, `add == FALSE`).

`<imm>` The immediate offset applied to the value of `<Rn>`. Any value in the range 0-255 is permitted. `<imm>` can be omitted, meaning an offset of 0.

`<Rm>` Contains the offset that is applied to the value of `<Rn>` to form the address.

Operation

```
if ConditionPassed() then
    if CurrentModeIsHyp() then UNPREDICTABLE;               // Hyp mode
    EncodingSpecificOperations();  NullCheckIfThumbEE(n);
    offset = if register_form then R[m] else imm32;
    offset_addr = if add then (R[n] + offset) else (R[n] - offset);
    address = if postindex then R[n] else offset_addr;
    R[t] = SignExtend(MemU_unpriv[address,1], 32);
    if postindex then R[n] = offset_addr;
```

Exceptions

Data Abort.

A8.8.88 LDRSH (immediate)

Load Register Signed Halfword (immediate) calculates an address from a base register value and an immediate offset, loads a halfword from memory, sign-extends it to form a 32-bit word, and writes it to a register. It can use offset, post-indexed, or pre-indexed addressing. For information about memory accesses see *Memory accesses* on page A8-294.

Encoding T1 ARMv6T2, ARMv7

```

The memory access is restricted as if the processor were running in User mode. This makes no difference if the processor is actually running in User mode.

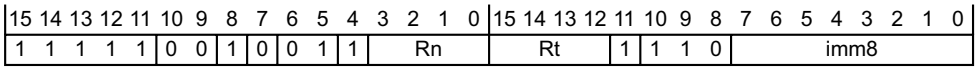
LDRSHT is UNPREDICTABLE in Hyp mode.

The Thumb instruction uses an offset addressing mode, that calculates the address used for the memory access from a base register value and an immediate offset, and leaves the base register unchanged.

The ARM instruction uses a post-indexed addressing mode, that uses a base register value as the address for the memory access, and calculates a new address from a base register value and an offset and writes it back to the base register. The offset can be an immediate value or a register value.

Encoding T1 ARMv6T2, ARMv7

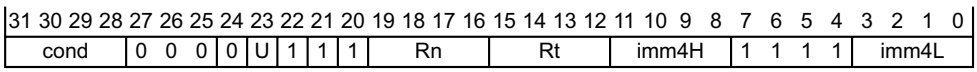
```
LDRSHT<c> <Rt>, [<Rn>, #<imm8>]
```



```
if Rn == '1111' then SEE LDRSH (literal);
t = UInt(Rt);  n = UInt(Rn);  postindex = FALSE;  add = TRUE;
register_form = FALSE;  imm32 = ZeroExtend(imm8, 32);
if t IN {13,15} then UNPREDICTABLE;
```

Encoding A1 ARMv6T2, ARMv7

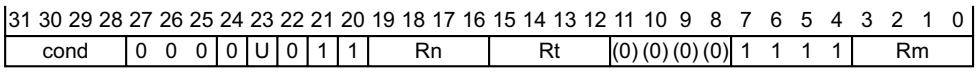
```
LDRSHT<c> <Rt>, [<Rn>] {, #+/-<imm8>}
```



```
t = UInt(Rt);  n = UInt(Rn);  postindex = TRUE;  add = (U == '1');
register_form = FALSE;  imm32 = ZeroExtend(imm4H:imm4L, 32);
if t == 15 || n == 15 || n == t then UNPREDICTABLE;
```

Encoding A2 ARMv6T2, ARMv7

```
LDRSHT<c> <Rt>, [<Rn>], +/-<Rm>
```



```
t = UInt(Rt);  n = UInt(Rn);  m = UInt(Rm);  postindex = TRUE;  add = (U == '1');
register_form = TRUE;
if t == 15 || n == 15 || n == t || m == 15 then UNPREDICTABLE;
```

Assembler syntax

`LDRSHT{<c>}{<q>}  <Rt>, [<Rn> {, #<imm>}]`	Offset: Thumb only
`LDRSHT{<c>}{<q>}  <Rt>, [<Rn>] {, #+/-<imm>}`	Post-indexed: ARM only
`LDRSHT{<c>}{<q>}  <Rt>, [<Rn>], +/-<Rm>`	Post-indexed: ARM only

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287.

`<Rt>` The destination register.

`<Rn>` The base register. The SP can be used.

`+/-` Is + or omitted if `<imm>` or the optionally shifted value of `<Rm>` is to be added to the base register value (`add == TRUE`), or – if it is to be subtracted (permitted in ARM instructions only, `add == FALSE`).

`<imm>` The immediate offset applied to the value of `<Rn>`. Any value in the range 0-255 is permitted. `<imm>` can be omitted, meaning an offset of 0.

`<Rm>` Contains the offset that is applied to the value of `<Rn>` to form the address.

Operation

```
if ConditionPassed() then
    if CurrentModeIsHyp() then UNPREDICTABLE;               // Hyp mode
    EncodingSpecificOperations();  NullCheckIfThumbEE(n);
    offset = if register_form then R[m] else imm32;
    offset_addr = if add then (R[n] + offset) else (R[n] - offset);
    address = if postindex then R[n] else offset_addr;
    data = MemU_unpriv[address,2];
    if postindex then R[n] = offset_addr;
    if UnalignedSupport() || address<0> = '0' then
        R[t] = SignExtend(data, 32);
    else // Can only apply before ARMv7
        R[t] = bits(32) UNKNOWN;
```

Exceptions

Data Abort.

A8.8.92 LDRT

Load Register Unprivileged loads a word from memory, and writes it to a register. For information about memory accesses see *Memory accesses* on page A8-294.

The memory access is restricted as if the processor were running in User mode. This makes no difference if the processor is actually running in User mode.

LDRT is UNPREDICTABLE in Hyp mode.

The Thumb instruction uses an offset addressing mode, that calculates the address used for the memory access from a base register value and an immediate offset, and leaves the base register unchanged.

The ARM instruction uses a post-indexed addressing mode, that uses a base register value as the address for the memory access, and calculates a new address from a base register value and an offset and writes it back to the base register. The offset can be an immediate value or an optionally-shifted register value.

Encoding T1 ARMv6T2, ARMv7

```
LDRT<c> <Rt>, [<Rn>, #<imm8>]
```

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	1	0	0	0	0	1	0	1	Rn				Rt				1	1	1	0	imm8							

```
if Rn == '1111' then SEE LDR (literal);
t = UInt(Rt);  n = UInt(Rn);  postindex = FALSE;  add = TRUE;
register_form = FALSE;  imm32 = ZeroExtend(imm8, 32);
if t IN {13,15} then UNPREDICTABLE;
```

Encoding A1 ARMv4*, ARMv5T*, ARMv6*, ARMv7

```
LDRT<c> <Rt>, [<Rn>] {, #+/-<imm12>}
```

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

```

Assembler syntax

`LDRT{<c>}{<q>}  <Rt>, [<Rn> {, #<imm>}]`	Offset: Thumb only
`LDRT{<c>}{<q>}  <Rt>, [<Rn>] {, #+/-<imm>}`	Post-indexed: ARM only
`LDRT{<c>}{<q>}  <Rt>, [<Rn>], +/-<Rm> {, <shift>}`	Post-indexed: ARM only

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287.

`<Rt>` The destination register.

`<Rn>` The base register. The SP can be used.

`+/-` Is + or omitted if `<imm>` or the optionally shifted value of `<Rm>` is to be added to the base register value (`add == TRUE`), or – if it is to be subtracted (permitted in ARM instructions only, `add == FALSE`).

`<imm>` The immediate offset applied to the value of `<Rn>`. Values are 0-255 for encoding T1, and 0-4095 for encoding A1. `<imm>` can be omitted, meaning an offset of 0.

`<Rm>` Contains the offset that is optionally shifted and applied to the value of `<Rn>` to form the address.

`<shift>` The shift to apply to the value read from `<Rm>`. If omitted, no shift is applied. *Shifts applied to a register* on page A8-291 describes the shifts and how they are encoded.

The pre-UAL syntax `LDR<c>T` is equivalent to `LDRT<c>`.

Operation

```
if ConditionPassed() then
    if CurrentModeIsHyp() then UNPREDICTABLE;               // Hyp mode
    EncodingSpecificOperations();  NullCheckIfThumbEE(n);
    offset = if register_form then Shift(R[m], shift_t, shift_n, APSR.C) else imm32;
    offset_addr = if add then (R[n] + offset) else (R[n] - offset);
    address = if postindex then R[n] else offset_addr;
    data = MemU_unpriv[address,4];
    if postindex then R[n] = offset_addr;
    if UnalignedSupport() || address<1:0> = '00' then
        R[t] = data;
    else // Can only apply before ARMv7
        if CurrentInstrSet() == InstrSet_ARM then
            R[t] = ROR(data, 8*UInt(address<1:0>));
        else
            R[t] = bits(32) UNKNOWN;
```

Exceptions

Data Abort.

A8.8.93 LEAVEX

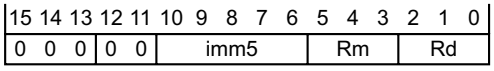
LEAVEX causes a change from ThumbEE to Thumb state, or has no effect in Thumb state. For details see *ENTERX, LEAVEX* on page A9-1116.

A8.8.94 LSL (immediate)

Logical Shift Left (immediate) shifts a register value left by an immediate number of bits, shifting in zeros, and writes the result to the destination register. It can optionally update the condition flags based on the result.

Encoding T1 ARMv4T, ARMv5T*, ARMv6*, ARMv7

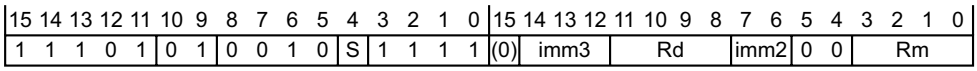
```
LSLS <Rd>, <Rm>, #<imm5>                    Outside IT block.
LSL<c> <Rd>, <Rm>, #<imm5>                  Inside IT block.
```



```
if imm5 == '00000' then SEE MOV (register);
d = UInt(Rd);  m = UInt(Rm);  setflags = !InITBlock();
(-, shift_n) = DecodeImmShift('00', imm5);
```

Encoding T2 ARMv6T2, ARMv7

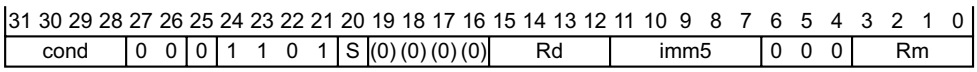
```
LSL{S}<c>.W <Rd>, <Rm>, #<imm5>
```



```
if (imm3:imm2) == '00000' then SEE MOV (register);
d = UInt(Rd);  m = UInt(Rm);  setflags = (S == '1');
(-, shift_n) = DecodeImmShift('00', imm3:imm2);
if d IN {13,15} || m IN {13,15} then UNPREDICTABLE;
```

Encoding A1 ARMv4*, ARMv5T*, ARMv6*, ARMv7

```
LSL{S}<c> <Rd>, <Rm>, #<imm5>
```



```
if Rd == '1111' && S == '1' then SEE SUBS PC, LR and related instructions;
if imm5 == '00000' then SEE MOV (register);
d = UInt(Rd);  m = UInt(Rm);  setflags = (S == '1');
(-, shift_n) = DecodeImmShift('00', imm5);
```

Assembler syntax

```
LSL{S}{<c>}{<q>}  {<Rd>,} <Rm>, #<imm5>
```

where:

S — If S is present, the instruction updates the flags. Otherwise, the flags are not updated.

<c>, <q> — See *Standard assembler syntax fields* on page A8-287.

<Rd> — The destination register.

In ARM instructions, if S is not specified and <Rd> is the PC, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode details of operations on ARM core registers* on page A2-47.

Note

Before ARMv7, this was a simple branch.

<Rm> — The first operand register. The PC can be used in ARM instructions.

<imm5> — The shift amount, in the range 1 to 31. See *Shifts applied to a register* on page A8-291.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    (result, carry) = Shift_C(R[m], SRType_LSL, shift_n, APSR.C);
    if d == 15 then          // Can only occur for ARM encoding
        ALUWritePC(result);  // setflags is always FALSE here
    else
        R[d] = result;
        if setflags then
            APSR.N = result<31>;
            APSR.Z = IsZeroBit(result);
            APSR.C = carry;
            // APSR.V unchanged
```

Exceptions

None.

A8.8.95 LSL (register)

Logical Shift Left (register) shifts a register value left by a variable number of bits, shifting in zeros, and writes the result to the destination register. The variable number of bits is read from the bottom byte of a register. It can optionally update the condition flags based on the result.

Encoding T1 ARMv4T, ARMv5T*, ARMv6*, ARMv7

```
LSLS   <Rdn>, <Rm>                    Outside IT block.
LSL<c> <Rdn>, <Rm>                    Inside IT block.
```

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	0	0	0	0	0	0	1	0	Rm			Rdn		

```
d = UInt(Rdn);  n = UInt(Rdn);  m = UInt(Rm);  setflags = !InITBlock();
```

Encoding T2 ARMv6T2, ARMv7

```
LSL{S}<c>.W <Rd>, <Rn>, <Rm>
```

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	1	0	1	0	0	0	0	S	Rn				1	1	1	1	Rd				0	0	0	0	Rm			

```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  setflags = (S == '1');
if d IN {13,15} || n IN {13,15} || m IN {13,15} then UNPREDICTABLE;
```

Encoding A1 ARMv4*, ARMv5T*, ARMv6*, ARMv7

```
LSL{S}<c> <Rd>, <Rn>, <Rm>
```

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond				0	0	0	1	1	0	1	S	(0)	(0)	(0)	(0)	Rd				Rm				0	0	0	1	Rn			

```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  setflags = (S == '1');
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE;
```

Assembler syntax

```
LSL{S}{<c>}{<q>}  {<Rd>,} <Rn>, <Rm>
```

where:

S	If S is present, the instruction updates the flags. Otherwise, the flags are not updated.
<c>, <q>	See *Standard assembler syntax fields* on page A8-287.
<Rd>	The destination register.
<Rn>	The first operand register.
<Rm>	The register whose bottom byte contains the amount to shift by.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shift_n = UInt(R[m]<7:0>);
    (result, carry) = Shift_C(R[n], SRType_LSL, shift_n, APSR.C);
    R[d] = result;
    if setflags then
        APSR.N = result<31>;
        APSR.Z = IsZeroBit(result);
        APSR.C = carry;
        // APSR.V unchanged
```

Exceptions

None.

A8.8.96 LSR (immediate)

Logical Shift Right (immediate) shifts a register value right by an immediate number of bits, shifting in zeros, and writes the result to the destination register. It can optionally update the condition flags based on the result.

Encoding T1 ARMv4T, ARMv5T*, ARMv6*, ARMv7

```
LSRS <Rd>, <Rm>, #<imm>                    Outside IT block.
LSR<c> <Rd>, <Rm>, #<imm>                  Inside IT block.
```

        APSR.C = carry;
        // APSR.V unchanged
```

Exceptions

None.

A8.8.98 MCR, MCR2

Move to Coprocessor from ARM core register passes the value of an ARM core register to a coprocessor. If no coprocessor can execute the instruction, an Undefined Instruction exception is generated.

This is a generic coprocessor instruction. Some of the fields have no functionality defined by the architecture and are free for use by the coprocessor instruction set designer. These are the `opc1`, `opc2`, `CRn`, and `CRm` fields. However, coprocessors CP8-CP15 are reserved for use by ARM, and this manual defines the valid `MCR` and `MCR2` instructions when `coproc` is in the range `p8-p15`. For more information see *Coprocessor support* on page A2-94.

In an implementation that includes the Virtualization Extensions, `MCR` accesses to system control registers can be trapped to Hyp mode, meaning that an attempt to execute an `MCR` instruction in a Non-secure mode other than Hyp mode, that would be permitted in the absence of the Hyp trap controls, generates a Hyp Trap exception. For more information, see *Traps to the hypervisor* on page B1-1247.

Note

Because of the range of possible traps to Hyp mode, the `MCR` pseudocode does not show these possible traps.

```

where:

2	If specified, selects encoding T2/A2. If omitted, selects encoding T1/A1.
<c>, <q>	See *Standard assembler syntax fields* on page A8-287. An ARM MCR2 instruction must be unconditional.
<coproc>	The name of the coprocessor. The generic coprocessor names are p0-p15.
<opc1>	Is a coprocessor-specific opcode in the range 0 to 7.
<Rt>	Is the ARM core register whose value is transferred to the coprocessor.
<CRn>	Is the destination coprocessor register.
<CRm>	Is an additional destination coprocessor register.
<opc2>	Is a coprocessor-specific opcode in the range 0-7. If omitted, <opc2> is assumed to be 0.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if !Coproc_Accepted(cp, ThisInstr()) then
        GenerateCoprocessorException();
    else
        Coproc_SendOneWord(R[t], cp, ThisInstr());
```

Exceptions

Undefined Instruction, Hyp Trap.

Uses of these instructions by specific coprocessors might generate other exceptions.

A8.8.99 MCRR, MCRR2

Move to Coprocessor from two ARM core registers passes the values of two ARM core registers to a coprocessor. If no coprocessor can execute the instruction, an Undefined Instruction exception is generated.

This is a generic coprocessor instruction. Some of the fields have no functionality defined by the architecture and are free for use by the coprocessor instruction set designer. These are the `opc1` and `CRm` fields. However, coprocessors CP8-CP15 are reserved for use by ARM, and this manual defines the valid `MCRR` and `MCRR2` instructions when `coproc` is in the range `p8-p15`. For more information see *Coprocessor support* on page A2-94.

In an implementation that includes the Virtualization Extensions, `MCRR` accesses to system control registers can be trapped to Hyp mode, meaning that an attempt to execute an `MCRR` instruction in a Non-secure mode other than Hyp mode, that would be permitted in the absence of the Hyp trap controls, generates a Hyp Trap exception. For more information, see *Traps to the hypervisor* on page B1-1247.

Note

Because of the range of possible traps to Hyp mode, the `MCRR` pseudocode does not show these possible traps.

Encoding T1/A1

ARMv6T2, ARMv7 for encoding T1
ARMv5TE*, ARMv6*, ARMv7 for encoding A1

```
MCRR<c> <coproc>, <opc1>, <Rt>, <Rt2>, <CRm>
```

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond				1	1	0	0	0	1	0	0	Rt2				Rt				coproc				opc1				CRm			

```
if coproc IN "101x" then SEE "Advanced SIMD and Floating-point";
t = UInt(Rt);  t2 = UInt(Rt2);  cp = UInt(coproc);
if t == 15 || t2 == 15 then UNPREDICTABLE;
if (t == 13 || t2 == 13) && (CurrentInstrSet() != InstrSet_ARM) then UNPREDICTABLE;
```

Encoding T2/A2

ARMv6T2, ARMv7 for encoding T2
ARMv6*, ARMv7 for encoding A2

```
MCRR2<c> <coproc>, <opc1>, <Rt>, <Rt2>, <CRm>
```

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	1	1	0	0	0	1	0	0	Rt2				Rt				coproc				opc1				CRm			

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	1	1	0	0	0	1	0	0	Rt2				Rt				coproc				opc1				CRm			

```
if coproc IN "101x" then UNDEFINED;
t = UInt(Rt);  t2 = UInt(Rt2);  cp = UInt(coproc);
if t == 15 || t2 == 15 then UNPREDICTABLE;
if (t == 13 || t2 == 13) && (CurrentInstrSet() != InstrSet_ARM) then UNPREDICTABLE;
```

Advanced SIMD and Floating-point

See *64-bit transfers between ARM core and extension registers* on page A7-279

Assembler syntax

```
MCRR{2}{<c>}{<q>}  <coproc>, {#}<opc1>, <Rt>, <Rt2>, <CRm>
```

where:

`2`	If specified, selects encoding T2/A2. If omitted, selects encoding T1/A1.
`<c>, <q>`	See *Standard assembler syntax fields* on page A8-287. An ARM `MCRR2` instruction must be unconditional.
`<coproc>`	The name of the coprocessor. The generic coprocessor names are p0-p15.
`<opc1>`	Is a coprocessor-specific opcode in the range 0 to 15.
`<Rt>`	Is the first ARM core register whose value is transferred to the coprocessor.
`<Rt2>`	Is the second ARM core register whose value is transferred to the coprocessor.
`<CRm>`	Is the destination coprocessor register.

Note

The relative significance of `Rt2` and `Rt` is IMPLEMENTATION DEFINED, but all uses within this manual treat `Rt2` as more significant than `Rt`

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if !Coproc_Accepted(cp, ThisInstr()) then
        GenerateCoprocessorException();
    else
        Coproc_SendTwoWords(R[t2], R[t], cp, ThisInstr());
```

Exceptions

Undefined Instruction, Hyp Trap.

Uses of these instructions by specific coprocessors might generate other exceptions.

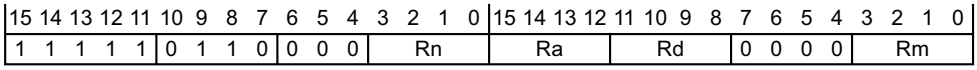
A8.8.100 MLA

Multiply Accumulate multiplies two register values, and adds a third register value. The least significant 32 bits of the result are written to the destination register. These 32 bits do not depend on whether the source register values are considered to be signed values or unsigned values.

In an ARM instruction, the condition flags can optionally be updated based on the result. Use of this option adversely affects performance on many processor implementations.

Encoding T1 ARMv6T2, ARMv7

```
MLA<c> <Rd>, <Rn>, <Rm>, <Ra>
```

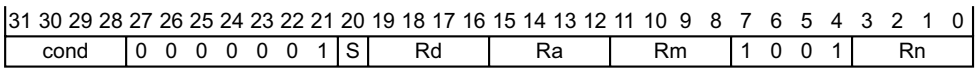


15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	1	0	1	1	0	0	0	0	Rn				Ra				Rd				0	0	0	0	Rm			

```
if Ra == '1111' then SEE MUL;
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  a = UInt(Ra);  setflags = FALSE;
if d IN {13,15} || n IN {13,15} || m IN {13,15} || a == 13 then UNPREDICTABLE;
```

Encoding A1 ARMv4*, ARMv5T*, ARMv6*, ARMv7

```
MLA{S}<c> <Rd>, <Rn>, <Rm>, <Ra>
```



31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

if d == 15 || n == 15 || m == 15 || a == 15 then UNPREDICTABLE;
if ArchVersion() < 6 && d == n then UNPREDICTABLE;
```

Assembler syntax

```
MLA{S}{<c>}{<q>}  <Rd>, <Rn>, <Rm>, <Ra>
```

where:

S	If S is present, the instruction updates the flags. Otherwise, the flags are not updated. S can be specified only for the ARM instruction set.
<c>, <q>	See *Standard assembler syntax fields* on page A8-287.
<Rd>	The destination register.
<Rn>	The first operand register.
<Rm>	The second operand register.
<Ra>	The register containing the accumulate value.

The pre-UAL syntax MLA<c>S is equivalent to MLAS<c>.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    operand1 = SInt(R[n]);  // operand1 = UInt(R[n]) produces the same final results
    operand2 = SInt(R[m]);  // operand2 = UInt(R[m]) produces the same final results
    addend   = SInt(R[a]);  // addend   = UInt(R[a]) produces the same final results
    result = operand1 * operand2 + addend;
    R[d] = result<31:0>;
    if setflags then
        APSR.N = result<31>;
        APSR.Z = IsZeroBit(result<31:0>);
        if ArchVersion() == 4 then
            APSR.C = bit UNKNOWN;
        // else APSR.C unchanged
        // APSR.V always unchanged
```

Exceptions

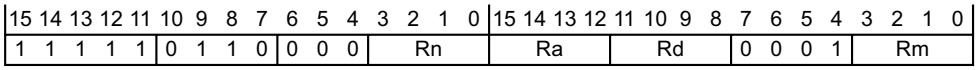
None.

A8.8.101 MLS

Multiply and Subtract multiplies two register values, and subtracts the product from a third register value. The least significant 32 bits of the result are written to the destination register. These 32 bits do not depend on whether the source register values are considered to be signed values or unsigned values.

Encoding T1 ARMv6T2, ARMv7

```
MLS<c> <Rd>, <Rn>, <Rm>, <Ra>
```



15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  a = UInt(Ra);
if d == 15 || n == 15 || m == 15 || a == 15 then UNPREDICTABLE;
```

Assembler syntax

```
MLS{<c>}{<q>}  <Rd>, <Rn>, <Rm>, <Ra>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287.

`<Rd>` The destination register.

`<Rn>` The first operand register.

`<Rm>` The second operand register.

`<Ra>` The register containing the accumulate value.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    operand1 = SInt(R[n]);  // operand1 = UInt(R[n]) produces the same final results
    operand2 = SInt(R[m]);  // operand2 = UInt(R[m]) produces the same final results
    addend   = SInt(R[a]);  // addend   = UInt(R[a]) produces the same final results
    result = addend - operand1 * operand2;
    R[d] = result<31:0>;
```

Exceptions

None.

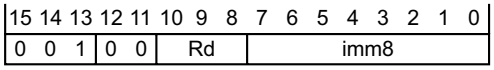
A8.8.102 MOV (immediate)

Move (immediate) writes an immediate value to the destination register. It can optionally update the condition flags based on the value.

Encoding T1 ARMv4T, ARMv5T*, ARMv6*, ARMv7

`MOVS <Rd>, #<imm8>` Outside IT block.

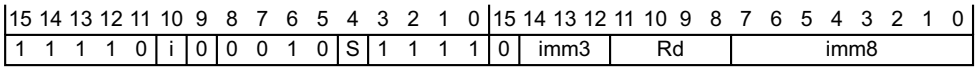
`MOV<c> <Rd>, #<imm8>` Inside IT block.



```
d = UInt(Rd);  setflags = !InITBlock();  imm32 = ZeroExtend(imm8, 32);  carry = APSR.C;
```

Encoding T2 ARMv6T2, ARMv7

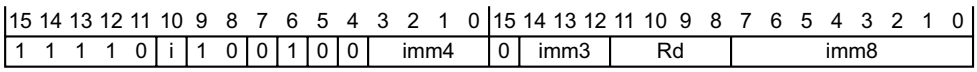
`MOV{S}<c>.W <Rd>, #<const>`



```
d = UInt(Rd);  setflags = (S == '1');  (imm32, carry) = ThumbExpandImm_C(i:imm3:imm8, APSR.C);
if d IN {13,15} then UNPREDICTABLE;
```

Encoding T3 ARMv6T2, ARMv7

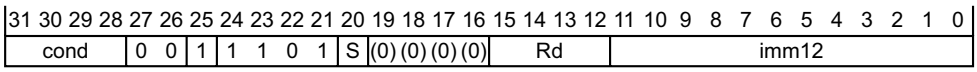
`MOVW<c> <Rd>, #<imm16>`



```
d = UInt(Rd);  setflags = FALSE;  imm32 = ZeroExtend(imm4:i:imm3:imm8, 32);
if d IN {13,15} then UNPREDICTABLE;
```

Encoding A1 ARMv4*, ARMv5T*, ARMv6*, ARMv7

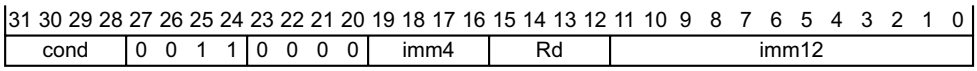
`MOV{S}<c> <Rd>, #<const>`



```
if Rd == '1111' && S == '1' then SEE SUBS PC, LR and related instructions;
d = UInt(Rd);  setflags = (S == '1');  (imm32, carry) = ARMExpandImm_C(imm12, APSR.C);
```

Encoding A2 ARMv6T2, ARMv7

`MOVW<c> <Rd>, #<imm16>`



```
d = UInt(Rd);  setflags = FALSE;  imm32 = ZeroExtend(imm4:imm12, 32);
if d == 15 then UNPREDICTABLE;
```

Assembler syntax

`MOV{S}{<c>}{<q>}  <Rd>, #<const>`	All encodings permitted
`MOVW{<c>}{<q>}  <Rd>, #<const>`	Only encoding T3 or A2 permitted

where:

`S` If `S` is present, the instruction updates the flags. Otherwise, the flags are not updated.

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287.

`<Rd>` The destination register. If `S` is specified and `<Rd>` is the PC, see *SUBS PC, LR (Thumb)* on page B9-2008 or *SUBS PC, LR and related instructions (ARM)* on page B9-2010.

In ARM instructions, if `S` is not specified and `<Rd>` is the PC, encoding A2 is not permitted, and for encoding A1 the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode details of operations on ARM core registers* on page A2-47.

Note

Before ARMv7, this was a simple branch.

`<const>` The immediate value to be placed in `<Rd>`. The range of values is 0-255 for encoding T1 and 0-65535 for encoding T3 or A2. See *Modified immediate constants in Thumb instructions* on page A6-232 or *Modified immediate constants in ARM instructions* on page A5-200 for the range of values for encoding T2 or A1.

When both 32-bit encodings are available for an instruction, encoding T2 or A1 is preferred to encoding T3 or A2 (if encoding T3 or A2 is required, use the `MOVW` syntax).

The pre-UAL syntax `MOV<c>S` is equivalent to `MOVS<c>`.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    result = imm32;
    if d == 15 then          // Can only occur for encoding A1
        ALUWritePC(result);  // setflags is always FALSE here
    else
        R[d] = result;
        if setflags then
            APSR.N = result<31>;
            APSR.Z = IsZeroBit(result);
            APSR.C = carry;
            // APSR.V unchanged
```

Exceptions

None.

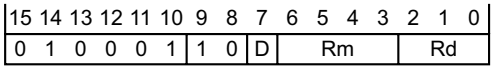
A8.8.103 MOV (register, Thumb)

Move (register) copies a value from a register to the destination register. It can optionally update the condition flags based on the value.

Encoding T1 ARMv6*, ARMv7 if <Rd> and <Rm> both from R0-R7
ARMv4T, ARMv5T*, ARMv6*, ARMv7 otherwise

```
MOV<c> <Rd>, <Rm>
```

If <Rd> is the PC, must be outside or last in IT block.

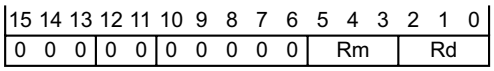


```
d = UInt(D:Rd);  m = UInt(Rm);  setflags = FALSE;
if d == 15 && InITBlock() && !LastInITBlock() then UNPREDICTABLE;
```

Encoding T2 ARMv4T, ARMv5T*, ARMv6*, ARMv7

```
MOVS <Rd>, <Rm>
```

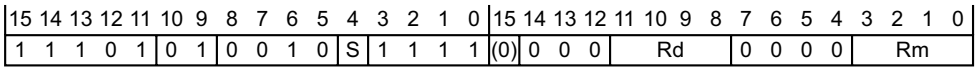
Not permitted in IT block



```
d = UInt(Rd);  m = UInt(Rm);  setflags = TRUE;
if InITBlock() then UNPREDICTABLE;
```

Encoding T3 ARMv6T2, ARMv7

```
MOV{S}<c>.W <Rd>, <Rm>
```



```
d = UInt(Rd);  m = UInt(Rm);  setflags = (S == '1');
if setflags && (d IN {13,15} || m IN {13,15}) then UNPREDICTABLE;
if !setflags && (d == 15 || m == 15 || (d == 13 && m == 13)) then UNPREDICTABLE;
```

Assembler syntax

```
MOV{S}{<c>}{<q>}  <Rd>, <Rm>
```

where:

S — If S is present, the instruction updates the flags. Otherwise, the flags are not updated.

<c>, <q> — See *Standard assembler syntax fields* on page A8-287.

<Rd> — The destination register. This register can be the SP or PC. S must not be specified if <Rd> is the SP.

If <Rd> is the PC and S is not specified:

- The instruction causes a branch to the address moved to the PC. This is a simple branch, see *Pseudocode details of operations on ARM core registers* on page A2-47.
- The instruction must either be outside an IT block or the last instruction of an IT block.

<Rm> — The source register. This register can be the SP or PC. S must not be specified if <Rm> is the SP or PC.

Encoding T3 is not permitted if:

- <Rd> or <Rm> is the PC
- both <Rd> and <Rm> are the SP.

Note

- ARM deprecates the use of the following MOV (register) instructions:
  - ones in which <Rd> is the SP or PC and <Rm> is also the SP or PC
  - ones in which S is specified and <Rm> is the SP, or <Rm> is the PC.
- See also *Changing between Thumb state and ARM state* on page A4-160 about the use of the MOV PC, LR instruction.

The pre-UAL syntax MOV<c>S is equivalent to MOVS<c>.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    result = R[m];
    if d == 15 then
        ALUWritePC(result);  // setflags is always FALSE here
    else
        R[d] = result;
        if setflags then
            APSR.N = result<31>;
            APSR.Z = IsZeroBit(result);
            // APSR.C unchanged
            // APSR.V unchanged
```

Exceptions

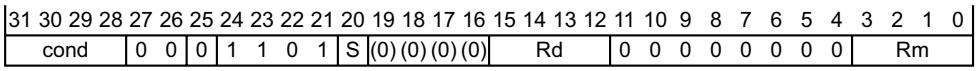
None.

A8.8.104 MOV (register, ARM)

Move (register) copies a value from a register to the destination register. It can optionally update the condition flags based on the value.

Encoding A1 ARMv4*, ARMv5T*, ARMv6*, ARMv7

```
MOV{S}<c> <Rd>, <Rm>
```



31 30 29 28	27 26	25	24 23 22 21	20	19 18 17 16	15 14 13 12	11 10 9 8 7 6 5 4	3 2 1 0
cond	0 0	0	1 1 0 1	S	(0) (0) (0) (0)	Rd	0 0 0 0 0 0 0 0	Rm

```
if Rd == '1111' && S == '1' then SEE SUBS PC, LR and related instructions;
d = UInt(Rd);  m = UInt(Rm);  setflags = (S == '1');
```

Assembler syntax

```
MOV{S}{<c>}{<q>}  <Rd>, <Rm>
```

where:

S — If S is present, the instruction updates the flags. Otherwise, the flags are not updated.

<c>, <q> — See *Standard assembler syntax fields* on page A8-287.

<Rd> — The destination register. If S is specified and <Rd> is the PC, see *SUBS PC, LR and related instructions (ARM)* on page B9-2010. This register can be the SP or PC.

If <Rd> is the PC and S is not specified, the instruction causes a branch to the address moved to the PC. This is an interworking branch, see *Pseudocode details of operations on ARM core registers* on page A2-47.

Note

Before ARMv7, this was a simple branch.

<Rm> — The source register. This register can be the SP or PC.

Note

- ARM deprecates the use of the following MOV (register) instructions:
  - ones in which <Rd> is the SP or PC and <Rm> is also the SP or PC
  - ones in which S is specified and <Rd> is the SP, <Rm> is the SP, or <Rm> is the PC.
- See also *Changing between Thumb state and ARM state* on page A4-160 about the use of the MOV PC, LR instruction.

The pre-UAL syntax MOV<c>S is equivalent to MOVS<c>.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    result = R[m];
    if d == 15 then
        ALUWritePC(result);  // setflags is always FALSE here
    else
        R[d] = result;
        if setflags then
            APSR.N = result<31>;
            APSR.Z = IsZeroBit(result);
            // APSR.C unchanged
            // APSR.V unchanged
```

Exceptions

None.

A8.8.105 MOV (shifted register)

For the special case of MOVS where <Rd> is the PC, see *SUBS PC, LR (Thumb)* on page B9-2008 and *SUBS PC, LR and related instructions (ARM)* on page B9-2010. Otherwise, MOV (shifted register) is a pseudo-instruction for ASR, LSL, LSR, ROR, and RRX. For more information see the following sections:

- *ASR (immediate)* on page A8-330
- *ASR (register)* on page A8-332
- *LSL (immediate)* on page A8-468
- *LSL (register)* on page A8-470
- *LSR (immediate)* on page A8-472
- *LSR (register)* on page A8-474
- *ROR (immediate)* on page A8-568
- *ROR (register)* on page A8-570
- *RRX* on page A8-572.

Assembler syntax

Table A8-3 shows the equivalences between MOV (shifted register) and other instructions.

Table A8-3 MOV (shifted register) equivalences

MOV instruction	Canonical form
MOV{S} <Rd>, <Rm>, ASR #<n>	ASR{S} <Rd>, <Rm>, #<n>
MOV{S} <Rd>, <Rm>, LSL #<n>	LSL{S} <Rd>, <Rm>, #<n>
MOV{S} <Rd>, <Rm>, LSR #<n>	LSR{S} <Rd>, <Rm>, #<n>
MOV{S} <Rd>, <Rm>, ROR #<n>	ROR{S} <Rd>, <Rm>, #<n>
MOV{S} <Rd>, <Rm>, ASR <Rs>	ASR{S} <Rd>, <Rm>, <Rs>
MOV{S} <Rd>, <Rm>, LSL <Rs>	LSL{S} <Rd>, <Rm>, <Rs>
MOV{S} <Rd>, <Rm>, LSR <Rs>	LSR{S} <Rd>, <Rm>, <Rs>
MOV{S} <Rd>, <Rm>, ROR <Rs>	ROR{S} <Rd>, <Rm>, <Rs>
MOV{S} <Rd>, <Rm>, RRX	RRX{S} <Rd>, <Rm>

Disassembly produces the canonical form of the instruction.

Exceptions

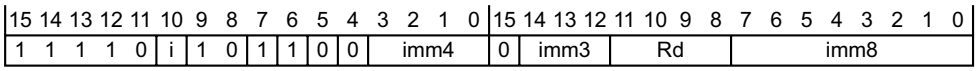
None.

A8.8.106 MOVT

Move Top writes an immediate value to the top halfword of the destination register. It does not affect the contents of the bottom halfword.

Encoding T1 ARMv6T2, ARMv7

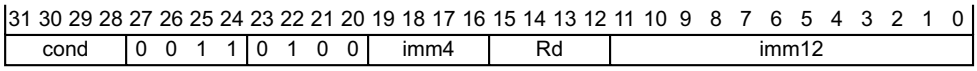
```
MOVT<c> <Rd>, #<imm16>
```



```
d = UInt(Rd);  imm16 = imm4:i:imm3:imm8;
if d IN {13,15} then UNPREDICTABLE;
```

Encoding A1 ARMv6T2, ARMv7

```
MOVT<c> <Rd>, #<imm16>
```



```
d = UInt(Rd);  imm16 = imm4:imm12;
if d == 15 then UNPREDICTABLE;
```

Assembler syntax

```
MOVT{<c>}{<q>}  <Rd>, #<imm16>
```

where:

<c>, <q> See *Standard assembler syntax fields* on page A8-287.

<Rd> The destination register.

<imm16> The immediate value to be written to <Rd>. It must be in the range 0-65535.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    R[d]<31:16> = imm16;
    // R[d]<15:0> unchanged
```

Exceptions

None.

A8.8.107 MRC, MRC2

Move to ARM core register from Coprocessor causes a coprocessor to transfer a value to an ARM core register or to the condition flags. If no coprocessor can execute the instruction, an Undefined Instruction exception is generated.

This is a generic coprocessor instruction. Some of the fields have no functionality defined by the architecture and are free for use by the coprocessor instruction set designer. These are the `opc1`, `opc2`, `CRn`, and `CRm` fields. However, coprocessors CP8-CP15 are reserved for use by ARM, and this manual defines the valid `MRC` and `MRC2` instructions when `coproc` is in the range `p8-p15`. For more information see *Coprocessor support* on page A2-94.

In an implementation that includes the Virtualization Extensions, `MRC` accesses to system control registers can be trapped to Hyp mode, meaning that an attempt to execute an `MRC` instruction in a Non-secure mode other than Hyp mode, that would be permitted in the absence of the Hyp trap controls, generates a Hyp Trap exception. For more information, see *Traps to the hypervisor* on page B1-1247.

Note

Because of the range of possible traps to Hyp mode, the `MRC` pseudocode does not show these possible traps.

Encoding T1/A1

ARMv6T2, ARMv7 for encoding T1
ARMv4*, ARMv5T*, ARMv6*, ARMv7 for encoding A1

```
MRC<c> <coproc>, <opc1>, <Rt>, <CRn>, <CRm>{, <opc2>}
```

```

Advanced SIMD and Floating-point

See *8, 16, and 32-bit transfer between ARM core and extension registers* on page A7-278

Assembler syntax

```
MRC{2}{<c>}{<q>}  <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}
```

where:

2	If specified, selects encoding T2/A2. If omitted, selects encoding T1/A1.
<c>, <q>	See *Standard assembler syntax fields* on page A8-287. An ARM MRC2 instruction must be unconditional.
<coproc>	The name of the coprocessor. The generic coprocessor names are p0-p15.
<opc1>	Is a coprocessor-specific opcode in the range 0 to 7.
<Rt>	Is the destination ARM core register. This register can be R0-R14 or APSR_nzcv. The last form writes bits[31:28] of the transferred value to the N, Z, C and V condition flags and is specified by setting the Rt field of the encoding to 0b1111. In pre-UAL assembler syntax, PC was written instead of APSR_nzcv to select this form.
<CRn>	Is the coprocessor register that contains the first operand.
<CRm>	Is an additional source or destination coprocessor register.
<opc2>	Is a coprocessor-specific opcode in the range 0 to 7. If omitted, <opc2> is assumed to be 0.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if !Coproc_Accepted(cp, ThisInstr()) then
        GenerateCoprocessorException();
    else
        value = Coproc_GetOneWord(cp, ThisInstr());
        if t != 15 then
            R[t] = value;
        else
            APSR.N = value<31>;
            APSR.Z = value<30>;
            APSR.C = value<29>;
            APSR.V = value<28>;
            // value<27:0> are not used.
```

Exceptions

Undefined Instruction, Hyp Trap.

Uses of these instructions by specific coprocessors might generate other exceptions.

A8.8.108 MRRC, MRRC2

Move to two ARM core registers from Coprocessor causes a coprocessor to transfer values to two ARM core registers. If no coprocessor can execute the instruction, an Undefined Instruction exception is generated.

This is a generic coprocessor instruction. Some of the fields have no functionality defined by the architecture and are free for use by the coprocessor instruction set designer. These are the `opc1` and `CRm` fields. However, coprocessors CP8-CP15 are reserved for use by ARM, and this manual defines the valid `MRRC` and `MRRC2` instructions when `coproc` is in the range `p8-p15`. For more information see *Coprocessor support* on page A2-94.

In an implementation that includes the Virtualization Extensions, `MRRC` accesses to system control registers can be trapped to Hyp mode, meaning that an attempt to execute an `MRRC` instruction in a Non-secure mode other than Hyp mode, that would be permitted in the absence of the Hyp trap controls, generates a Hyp Trap exception. For more information, see *Traps to the hypervisor* on page B1-1247.

Note

Because of the range of possible traps to Hyp mode, the `MRRC` pseudocode does not show these possible traps.

Encoding T1/A1

ARMv6T2, ARMv7 for encoding T1
ARMv5TE*, ARMv6*, ARMv7 for encoding A1

```
MRRC<c> <coproc>, <opc>, <Rt>, <Rt2>, <CRm>
```

if t == 15 || t2 == 15 || t == t2 then UNPREDICTABLE;
if (t == 13 || t2 == 13) && (CurrentInstrSet() != InstrSet_ARM) then UNPREDICTABLE;
```

Advanced SIMD and Floating-point

See *64-bit transfers between ARM core and extension registers* on page A7-279

Assembler syntax

```
MRRC{2}{<c>}{<q>}  <coproc>, {#}<opc1>, <Rt>, <Rt2>, <CRm>
```

where:

2	If specified, selects encoding T2/A2. If omitted, selects encoding T1/A1.
<c>, <q>	See *Standard assembler syntax fields* on page A8-287. An ARM MRRC2 instruction must be unconditional.
<coproc>	The name of the coprocessor. The generic coprocessor names are p0-p15.
<opc1>	Is a coprocessor-specific opcode in the range 0 to 15.
<Rt>	Is the first destination ARM core register.
<Rt2>	Is the second destination ARM core register.
<CRm>	Is the coprocessor register that supplies the data to be transferred.

Note

The relative significance of Rt2 and Rt is IMPLEMENTATION DEFINED, but all uses within this manual treat Rt2 as more significant than Rt

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if !Coproc_Accepted(cp, ThisInstr()) then
        GenerateCoprocessorException();
    else
        (R[t2], R[t]) = Coproc_GetTwoWords(cp, ThisInstr());
```

Exceptions

Undefined Instruction, Hyp Trap.

Uses of these instructions by specific coprocessors might generate other exceptions.

A8.8.109 MRS

Move to Register from Special register moves the value from the APSR into an ARM core register.

For details of system level use of this instruction, see *MRS* on page B9-1988.

Encoding T1 ARMv6T2, ARMv7

```
MRS<c> <Rd>, <spec_reg>
```

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	0	0	1	1	1	1	1	0	(1)	(1)	(1)	(1)	1	0	(0)	0	Rd				(0)	(0)	0	(0)	(0)	(0)	(0)	(0)

```
d = UInt(Rd);
if d IN {13,15} then UNPREDICTABLE;
```

Encoding A1 ARMv4*, ARMv5T*, ARMv6*, ARMv7

```
MRS<c> <Rd>, <spec_reg>
```

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond				0	0	0	1	0	0	0	0	(1)	(1)	(1)	(1)	Rd				(0)	(0)	0	(0)	0	0	0	0	(0)	(0)	(0)	(0)

```
d = UInt(Rd);
if d == 15 then UNPREDICTABLE;
```

Assembler syntax

```
MRS{<c>}{<q>}  <Rd>, <spec_reg>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287.

`<Rd>` The destination register.

`<spec_reg>` Is one of:

- `APSR`
- `CPSR`.

When the `MRS` instruction is executed in User mode, `CPSR` is treated as a synonym of `APSR`.

ARM recommends that application level software uses the `APSR` form. For more information, see *The Application Program Status Register (APSR)* on page A2-49.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    R[d] = APSR;
```

Exceptions

None.

A8.8.110 MRS (Banked register)

Move to Register from Banked or Special register is a system instruction, see *MRS (Banked register)* on page B9-1990.

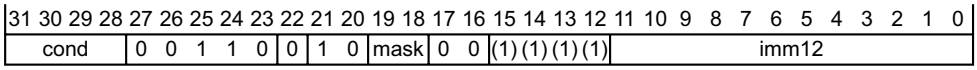
A8.8.111 MSR (immediate)

Move immediate value to Special register moves selected bits of an immediate value to the corresponding bits in the APSR.

For details of system level use of this instruction, see *MSR (immediate)* on page B9-1994.

Encoding A1 ARMv4*, ARMv5T*, ARMv6*, ARMv7

```
MSR<c> <spec_reg>, #<const>
```



```
if mask == '00' then SEE "Related encodings";
imm32 = ARMExpandImm(imm12);  write_nzcvq = (mask<1> == '1');  write_g = (mask<0> == '1');
```

Related encodings See *MSR (immediate), and hints* on page A5-206.

Assembler syntax

```
MSR{<c>}{<q>}  <spec_reg>, #<imm>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287.

`<spec_reg>` Is one of:

- `APSR_<bits>`
- `CPSR_<fields>`.

ARM recommends that application level software uses the `APSR` forms. For more information, see *The Application Program Status Register (APSR)* on page A2-49.

`<imm>` Is the immediate value to be transferred to `<spec_reg>`. See *Modified immediate constants in ARM instructions* on page A5-200 for the range of values.

`<bits>` Is one of `nzcvq`, `g`, or `nzcvqg`.

In the A and R profiles:

- `APSR_nzcvq` is the same as `CPSR_f`
- `APSR_g` is the same as `CPSR_s`
- `APSR_nzcvqg` is the same as `CPSR_fs`.

`<fields>` Is a sequence of one or more of the following: `s`, `f`.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if write_nzcvq then
        APSR.N = imm32<31>;
        APSR.Z = imm32<30>;
        APSR.C = imm32<29>;
        APSR.V = imm32<28>;
        APSR.Q = imm32<27>;
    if write_g then
        APSR.GE = imm32<19:16>;
```

Exceptions

None.

Usage

For details of the APSR see *The Application Program Status Register (APSR)* on page A2-49. Because of the Do-Not-Modify nature of its reserved bits, the immediate form of `MSR` is normally only useful at the Application level for writing to `APSR_nzcvq` (`CPSR_f`).

For the A and R profiles, *MSR (immediate)* on page B9-1994 describes additional functionality that is available using the reserved bits. This includes some deprecated functionality that is also available to unprivileged software and therefore can be used at the Application level.

A8.8.112 MSR (register)

Move to Special register from ARM core register moves selected bits of an ARM core register to the APSR.

For details of system level use of this instruction, see *MSR (register)* on page B9-1996.

Encoding T1 ARMv6T2, ARMv7

```
MSR<c> <spec_reg>, <Rn>
```

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	0	0	1	1	1	0	0	0	Rn				1	0	(0)	0	mask		0	0	(0)	(0)	0	(0)	(0)	(0)	(0)	(0)

```
n = UInt(Rn);  write_nzcvq = (mask<1> == '1');  write_g = (mask<0> == '1');
if mask == '00' then UNPREDICTABLE;
if n IN {13,15} then UNPREDICTABLE;
```

Encoding A1 ARMv4*, ARMv5T*, ARMv6*, ARMv7

```
MSR<c> <spec_reg>, <Rn>
```

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond				0	0	0	1	0	0	1	0	mask		0	0	(1)	(1)	(1)	(1)	(0)	(0)	0	(0)	0	0	0	0	Rn			

```
n = UInt(Rn);  write_nzcvq = (mask<1> == '1');  write_g = (mask<0> == '1');
if mask == '00' then UNPREDICTABLE;
if n == 15 then UNPREDICTABLE;
```

Assembler syntax

```
MSR{<c>}{<q>}  <spec_reg>, <Rn>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287.

`<spec_reg>` Is one of:

- `APSR_<bits>`
- `CPSR_<fields>`.

ARM recommends that application level software uses the `APSR` form. For more information, see *The Application Program Status Register (APSR)* on page A2-49.

`<Rn>` Is the ARM core register to be transferred to `<spec_reg>`.

`<bits>` Is one of `nzcvq`, `g`, or `nzcvqg`.

In the A and R profiles:

- `APSR_nzcvq` is the same as `CPSR_f`
- `APSR_g` is the same as `CPSR_s`
- `APSR_nzcvqg` is the same as `CPSR_fs`.

`<fields>` Is a sequence of one or more of the following: `s`, `f`.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if write_nzcvq then
        APSR.N = R[n]<31>;
        APSR.Z = R[n]<30>;
        APSR.C = R[n]<29>;
        APSR.V = R[n]<28>;
        APSR.Q = R[n]<27>;
    if write_g then
        APSR.GE = R[n]<19:16>;
```

Exceptions

None.

Usage

For details of the APSR see *The Application Program Status Register (APSR)* on page A2-49. Because of the Do-Not-Modify nature of its reserved bits, a read-modify-write sequence is normally needed when the `MSR` instruction is being used at Application level and its destination is not `APSR_nzcvq` (`CPSR_f`).

For the A and R profiles, *MSR (register)* on page B9-1996 describes additional functionality that is available using the reserved bits. This includes some deprecated functionality that is also available to unprivileged software and therefore can be used at the Application level.

A8.8.113 MSR (Banked register)

Move to Banked or Special register from ARM core register is a system instruction, see *MSR (Banked register)* on page B9-1992.

A8.8.114 MUL

Multiply multiplies two register values. The least significant 32 bits of the result are written to the destination register. These 32 bits do not depend on whether the source register values are considered to be signed values or unsigned values.

Optionally, it can update the condition flags based on the result. In the Thumb instruction set, this option is limited to only a few forms of the instruction. Use of this option adversely affects performance on many processor implementations.

Encoding T1 ARMv4T, ARMv5T*, ARMv6*, ARMv7

```
MULS <Rdm>, <Rn>, <Rdm>                    Outside IT block.
MUL<c> <Rdm>, <Rn>, <Rdm>                  Inside IT block.
```

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	0	0	0	0	1	1	0	1	Rn			Rdm		

```
d = UInt(Rdm);  n = UInt(Rn);  m = UInt(Rdm);  setflags = !InITBlock();
if ArchVersion() < 6 && d == n then UNPREDICTABLE;
```

Encoding T2 ARMv6T2, ARMv7

```
MUL<c> <Rd>, <Rn>, <Rm>
```

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	1	0	1	1	0	0	0	0	Rn				1	1	1	1	Rd				0	0	0	0	Rm			

```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  setflags = FALSE;
if d IN {13,15} || n IN {13,15} || m IN {13,15} then UNPREDICTABLE;
```

Encoding A1 ARMv4*, ARMv5T*, ARMv6*, ARMv7

```
MUL{S}<c> <Rd>, <Rn>, <Rm>
```

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond				0	0	0	0	0	0	0	S	Rd				(0)	(0)	(0)	(0)	Rm				1	0	0	1	Rn			

```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  setflags = (S == '1');
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE;
if ArchVersion() < 6 && d == n then UNPREDICTABLE;
```

Assembler syntax

```
MUL{S}{<c>}{<q>}  <Rd>, <Rn>{, <Rm>}
```

where:

S	If S is present, the instruction updates the flags. Otherwise, the flags are not updated. In the Thumb instruction set, S can be specified only if both <Rn> and <Rm> are R0-R7 and the instruction is outside an IT block.
<c>, <q>	See *Standard assembler syntax fields* on page A8-287.
<Rd>	The destination register.
<Rn>	The first operand register.
<Rm>	The second operand register. If omitted, <Rd> is used.

Note

Issues A and B of this document showed the MUL syntax as MUL{S}{<c>}{<q>} {<Rd>, }<Rn>, <Rm>. The <Rm> register is now made optional because omitting <Rd> can generate UNPREDICTABLE instructions in some cases. Some assembler versions might not support this revised specification.

The pre-UAL syntax MUL<c>S is equivalent to MULS<c>.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    operand1 = SInt(R[n]);  // operand1 = UInt(R[n]) produces the same final results
    operand2 = SInt(R[m]);  // operand2 = UInt(R[m]) produces the same final results
    result = operand1 * operand2;
    R[d] = result<31:0>;
    if setflags then
        APSR.N = result<31>;
        APSR.Z = IsZeroBit(result<31:0>);
        if ArchVersion() == 4 then
            APSR.C = bit UNKNOWN;
        // else APSR.C unchanged
        // APSR.V always unchanged
```

Exceptions

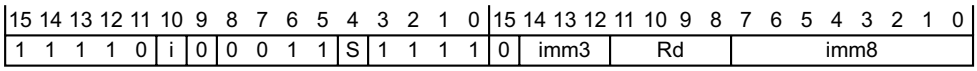
None.

A8.8.115 MVN (immediate)

Bitwise NOT (immediate) writes the bitwise inverse of an immediate value to the destination register. It can optionally update the condition flags based on the value.

Encoding T1 ARMv6T2, ARMv7

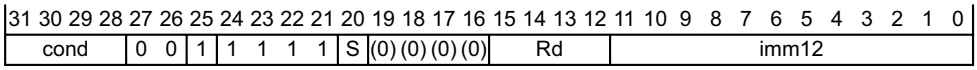
```
MVN{S}<c> <Rd>, #<const>
```



```
d = UInt(Rd);  setflags = (S == '1');
(imm32, carry) = ThumbExpandImm_C(i:imm3:imm8, APSR.C);
if d IN {13,15} then UNPREDICTABLE;
```

Encoding A1 ARMv4*, ARMv5T*, ARMv6*, ARMv7

```
MVN{S}<c> <Rd>, #<const>
```



```
if Rd == '1111' && S == '1' then SEE SUBS PC, LR and related instructions;
d = UInt(Rd);  setflags = (S == '1');
(imm32, carry) = ARMExpandImm_C(imm12, APSR.C);
```

Assembler syntax

```
MVN{S}{<c>}{<q>}  <Rd>, #<const>
```

where:

`S` If `S` is present, the instruction updates the flags. Otherwise, the flags are not updated.

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287.

`<Rd>` The destination register. If `S` is specified and `<Rd>` is the PC, see *SUBS PC, LR (Thumb)* on page B9-2008 or *SUBS PC, LR and related instructions (ARM)* on page B9-2010.

In ARM instructions, if `S` is not specified and `<Rd>` is the PC, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode details of operations on ARM core registers* on page A2-47.

Note

Before ARMv7, this was a simple branch.

`<const>` The immediate value to be bitwise inverted. See *Modified immediate constants in Thumb instructions* on page A6-232 or *Modified immediate constants in ARM instructions* on page A5-200 for the range of values.

The pre-UAL syntax `MVN<c>S` is equivalent to `MVNS<c>`.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    result = NOT(imm32);
    if d == 15 then          // Can only occur for ARM encoding
        ALUWritePC(result);  // setflags is always FALSE here
    else
        R[d] = result;
        if setflags then
            APSR.N = result<31>;
            APSR.Z = IsZeroBit(result);
            APSR.C = carry;
            // APSR.V unchanged
```

Exceptions

None.

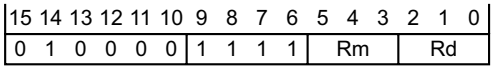
A8.8.116 MVN (register)

Bitwise NOT (register) writes the bitwise inverse of a register value to the destination register. It can optionally update the condition flags based on the result.

Encoding T1 ARMv4T, ARMv5T*, ARMv6*, ARMv7

`MVNS <Rd>, <Rm>` Outside IT block.

`MVN<c> <Rd>, <Rm>` Inside IT block.



15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	0	0	0	0	1	1	1	1	Rm			Rd		

```
d = UInt(Rd);  m = UInt(Rm);  setflags = !InITBlock();
(shift_t, shift_n) = (SRType_LSL, 0);
```

Encoding T2 ARMv6T2, ARMv7

`MVN{S}<c>.W <Rd>, <Rm>{, <shift>}`

```
if Rd == '1111' && S == '1' then SEE SUBS PC, LR and related instructions;
d = UInt(Rd);  m = UInt(Rm);  setflags = (S == '1');
(shift_t, shift_n) = DecodeImmShift(type, imm5);
```

Assembler syntax

```
MVN{S}{<c>}{<q>}  <Rd>, <Rm> {, <shift>}
```

where:

S — If S is present, the instruction updates the flags. Otherwise, the flags are not updated.

<c>, <q> — See *Standard assembler syntax fields* on page A8-287.

<Rd> — The destination register. If S is specified and <Rd> is the PC, see *SUBS PC, LR (Thumb)* on page B9-2008 or *SUBS PC, LR and related instructions (ARM)* on page B9-2010.

In ARM instructions, if S is not specified and <Rd> is the PC, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode details of operations on ARM core registers* on page A2-47.

Note

Before ARMv7, this was a simple branch.

<Rm> — The register that is optionally shifted and used as the source register. The PC can be used in ARM instructions.

<shift> — The shift to apply to the value read from <Rm>. If present, encoding T1 is not permitted. If absent, no shift is applied and all encodings are permitted. *Shifts applied to a register* on page A8-291 describes the shifts and how they are encoded.

The pre-UAL syntax MVN<c>S is equivalent to MVNS<c>.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    (shifted, carry) = Shift_C(R[m], shift_t, shift_n, APSR.C);
    result = NOT(shifted);
    if d == 15 then          // Can only occur for ARM encoding
        ALUWritePC(result);  // setflags is always FALSE here
    else
        R[d] = result;
        if setflags then
            APSR.N = result<31>;
            APSR.Z = IsZeroBit(result);
            APSR.C = carry;
            // APSR.V unchanged
```

Exceptions

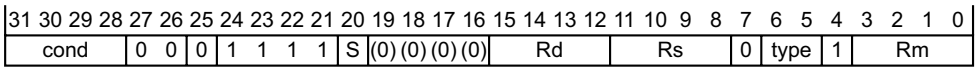
None.

A8.8.117 MVN (register-shifted register)

Bitwise NOT (register-shifted register) writes the bitwise inverse of a register-shifted register value to the destination register. It can optionally update the condition flags based on the result.

Encoding A1 ARMv4*, ARMv5T*, ARMv6*, ARMv7

```
MVN{S}<c> <Rd>, <Rm>, <type> <Rs>
```



31 30 29 28	27 26	25	24 23 22 21	20	19 18 17 16	15 14 13 12	11 10 9 8	7	6 5	4	3 2 1 0
cond	0 0	0	1 1 1 1	S	(0) (0) (0) (0)	Rd	Rs	0	type	1	Rm

```
d = UInt(Rd);  m = UInt(Rm);  s = UInt(Rs);
setflags = (S == '1');  shift_t = DecodeRegShift(type);
if d == 15 || m == 15 || s == 15 then UNPREDICTABLE;
```

Assembler syntax

```
MVN{S}{<c>}{<q>}  <Rd>, <Rm>, <type>  <Rs>
```

where:

S — If S is present, the instruction updates the flags. Otherwise, the flags are not updated.

<c>, <q> — See *Standard assembler syntax fields* on page A8-287.

<Rd> — The destination register.

<Rm> — The register that is shifted and used as the operand.

<type> — The type of shift to apply to the value read from <Rm>. It must be one of:

- ASR — Arithmetic shift right, encoded as type = 0b10.
- LSL — Logical shift left, encoded as type = 0b00.
- LSR — Logical shift right, encoded as type = 0b01.
- ROR — Rotate right, encoded as type = 0b11.

<Rs> — The register whose bottom byte contains the amount to shift by.

The pre-UAL syntax MVN<c>S is equivalent to MVNS<c>.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shift_n = UInt(R[s]<7:0>);
    (shifted, carry) = Shift_C(R[m], shift_t, shift_n, APSR.C);
    result = NOT(shifted);
    R[d] = result;
    if setflags then
        APSR.N = result<31>;
        APSR.Z = IsZeroBit(result);
        APSR.C = carry;
        // APSR.V unchanged
```

Exceptions

None.

A8.8.118 NEG

Negate is a pre-UAL synonym for RSB (immediate) with an immediate value of 0. For details see *RSB (immediate)* on page A8-574.

Assembler syntax

```
NEG{<c>}{<q>}  <Rd>, <Rm>
```

This is equivalent to:

```
RSBS{<c>}{<q>}  <Rd>, <Rm>, #0
```

Exceptions

None.

A8.8.119 NOP

No Operation does nothing. This instruction can be used for instruction alignment purposes.

See *Pre-UAL pseudo-instruction NOP* on page AppxH-2472 for details of NOP before the introduction of UAL and the ARMv6K and ARMv6T2 architecture variants.

Note

The timing effects of including a NOP instruction in a program are not guaranteed. It can increase execution time, leave it unchanged, or even reduce it. Therefore, NOP instructions are not suitable for timing loops.

Encoding T1 ARMv6T2, ARMv7

```
NOP<c>
```

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

```
// No additional decoding required
```

Assembler syntax

```
NOP{<c>}{<q>}
```

where:

`{<c>}{<q>}` See *Standard assembler syntax fields* on page A8-287.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    // Do nothing
```

Exceptions

None.

A8.8.120 ORN (immediate)

Bitwise OR NOT (immediate) performs a bitwise (inclusive) OR of a register value and the complement of an immediate value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

Encoding T1 ARMv6T2, ARMv7

```
ORN{S}<c> <Rd>, <Rn>, #<const>
```

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

```
if Rn == '1111' then SEE MVN (immediate);
d = UInt(Rd);  n = UInt(Rn);  setflags = (S == '1');
(imm32, carry) = ThumbExpandImm_C(i:imm3:imm8, APSR.C);
if d IN {13,15} || n == 13 then UNPREDICTABLE;
```

Assembler syntax

```
ORN{S}{<c>}{<q>}  {<Rd>,} <Rn>, #<const>
```

where:

S	If S is present, the instruction updates the flags. Otherwise, the flags are not updated.
<c>, <q>	See *Standard assembler syntax fields* on page A8-287.
<Rd>	The destination register.
<Rn>	The register that contains the operand.
<const>	The immediate value to be bitwise inverted and ORed with the value obtained from <Rn>. See *Modified immediate constants in Thumb instructions* on page A6-232 for the range of values.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    result = R[n] OR NOT(imm32);
    R[d] = result;
    if setflags then
        APSR.N = result<31>;
        APSR.Z = IsZeroBit(result);
        APSR.C = carry;
        // APSR.V unchanged
```

Exceptions

None.

A8.8.121 ORN (register)

Bitwise OR NOT (register) performs a bitwise (inclusive) OR of a register value and the complement of an optionally-shifted register value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

Encoding T1 ARMv6T2, ARMv7

```
ORN{S}<c> <Rd>, <Rn>, <Rm>{, <shift>}
```

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

```
if Rn == '1111' then SEE MVN (register);
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  setflags = (S == '1');
(shift_t, shift_n) = DecodeImmShift(type, imm3:imm2);
if d IN {13,15} || n == 13 || m IN {13,15} then UNPREDICTABLE;
```

Assembler syntax

```
ORN{S}{<c>}{<q>}  {<Rd>,} <Rn>, <Rm> {, <shift>}
```

where:

`S`	If `S` is present, the instruction updates the flags. Otherwise, the flags are not updated.
`<c>, <q>`	See *Standard assembler syntax fields* on page A8-287.
`<Rd>`	The destination register.
`<Rn>`	The first operand register.
`<Rm>`	The register that is optionally shifted and used as the second operand.
`<shift>`	The shift to apply to the value read from `<Rm>`. If omitted, no shift is applied. *Shifts applied to a register* on page A8-291 describes the shifts and how they are encoded.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    (shifted, carry) = Shift_C(R[m], shift_t, shift_n, APSR.C);
    result = R[n] OR NOT(shifted);
    R[d] = result;
    if setflags then
        APSR.N = result<31>;
        APSR.Z = IsZeroBit(result);
        APSR.C = carry;
        // APSR.V unchanged
```

Exceptions

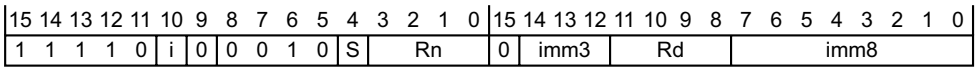
None.

A8.8.122 ORR (immediate)

Bitwise OR (immediate) performs a bitwise (inclusive) OR of a register value and an immediate value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

Encoding T1 ARMv6T2, ARMv7

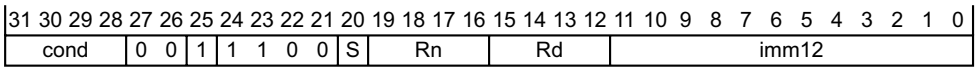
```
ORR{S}<c> <Rd>, <Rn>, #<const>
```



```
if Rn == '1111' then SEE MOV (immediate);
d = UInt(Rd);  n = UInt(Rn);  setflags = (S == '1');
(imm32, carry) = ThumbExpandImm_C(i:imm3:imm8, APSR.C);
if d IN {13,15} || n == 13 then UNPREDICTABLE;
```

Encoding A1 ARMv4*, ARMv5T*, ARMv6*, ARMv7

```
ORR{S}<c> <Rd>, <Rn>, #<const>
```



```
if Rd == '1111' && S == '1' then SEE SUBS PC, LR and related instructions;
d = UInt(Rd);  n = UInt(Rn);  setflags = (S == '1');
(imm32, carry) = ARMExpandImm_C(imm12, APSR.C);
```

Assembler syntax

```
ORR{S}{<c>}{<q>}  {<Rd>,} <Rn>, #<const>
```

where:

S — If S is present, the instruction updates the flags. Otherwise, the flags are not updated.

<c>, <q> — See *Standard assembler syntax fields* on page A8-287.

<Rd> — The destination register. If S is specified and <Rd> is the PC, see *SUBS PC, LR (Thumb)* on page B9-2008 or *SUBS PC, LR and related instructions (ARM)* on page B9-2010.

In ARM instructions, if S is not specified and <Rd> is the PC, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode details of operations on ARM core registers* on page A2-47.

Note

Before ARMv7, this was a simple branch.

<Rn> — The register that contains the operand. The PC can be used in ARM instructions.

<const> — The immediate value to be bitwise ORed with the value obtained from <Rn>. See *Modified immediate constants in Thumb instructions* on page A6-232 or *Modified immediate constants in ARM instructions* on page A5-200 for the range of values.

The pre-UAL syntax ORR<c>S is equivalent to ORRS<c>.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    result = R[n] OR imm32;
    if d == 15 then          // Can only occur for ARM encoding
        ALUWritePC(result);  // setflags is always FALSE here
    else
        R[d] = result;
        if setflags then
            APSR.N = result<31>;
            APSR.Z = IsZeroBit(result);
            APSR.C = carry;
            // APSR.V unchanged
```

Exceptions

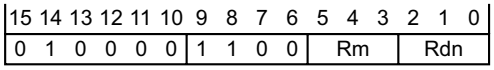
None.

A8.8.123 ORR (register)

Bitwise OR (register) performs a bitwise (inclusive) OR of a register value and an optionally-shifted register value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

Encoding T1 ARMv4T, ARMv5T*, ARMv6*, ARMv7

```
ORRS   <Rdn>, <Rm>          Outside IT block.
ORR<c> <Rdn>, <Rm>          Inside IT block.
```

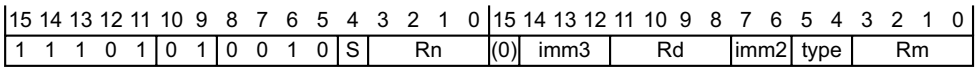


15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	0	0	0	0	1	1	0	0	Rm			Rdn		

```
d = UInt(Rdn);  n = UInt(Rdn);  m = UInt(Rm);  setflags = !InITBlock();
(shift_t, shift_n) = (SRType_LSL, 0);
```

Encoding T2 ARMv6T2, ARMv7

```
ORR{S}<c>.W <Rd>, <Rn>, <Rm>{, <shift>}
```

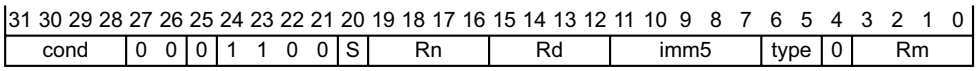


15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	0	1	0	1	0	0	1	0	S	Rn				(0)	imm3			Rd				imm2		type		Rm			

```
if Rn == '1111' then SEE "Related encodings";
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  setflags = (S == '1');
(shift_t, shift_n) = DecodeImmShift(type, imm3:imm2);
if d IN {13,15} || n == 13 || m IN {13,15} then UNPREDICTABLE;
```

Encoding A1 ARMv4*, ARMv5T*, ARMv6*, ARMv7

```
ORR{S}<c> <Rd>, <Rn>, <Rm>{, <shift>}
```



31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond				0	0	0	1	1	0	0	S	Rn				Rd				imm5					type		0	Rm			

```
if Rd == '1111' && S == '1' then SEE SUBS PC, LR and related instructions;
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  setflags = (S == '1');
(shift_t, shift_n) = DecodeImmShift(type, imm5);
```

Related encodings See *Move register and immediate shifts* on page A6-244.

Assembler syntax

```
ORR{S}{<c>}{<q>}  {<Rd>,} <Rn>, <Rm> {, <shift>}
```

where:

S — If S is present, the instruction updates the flags. Otherwise, the flags are not updated.

<c>, <q> — See *Standard assembler syntax fields* on page A8-287.

<Rd> — The destination register. If S is specified and <Rd> is the PC, see *SUBS PC, LR (Thumb)* on page B9-2008 or *SUBS PC, LR and related instructions (ARM)* on page B9-2010.

In ARM instructions, if S is not specified and <Rd> is the PC, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode details of operations on ARM core registers* on page A2-47.

Note

Before ARMv7, this was a simple branch.

<Rn> — The first operand register. The PC can be used in ARM instructions.

<Rm> — The register that is optionally shifted and used as the second operand. The PC can be used in ARM instructions.

<shift> — The shift to apply to the value read from <Rm>. If present, encoding T1 is not permitted. If absent, no shift is applied and all encodings are permitted. *Shifts applied to a register* on page A8-291 describes the shifts and how they are encoded.

In Thumb assembly:

- outside an IT block, if `ORRS <Rd>, <Rn>, <Rd>` is written with <Rd> and <Rn> both in the range R0-R7, it is assembled using encoding T1 as though `ORRS <Rd>, <Rn>` had been written
- inside an IT block, if `ORR<c> <Rd>, <Rn>, <Rd>` is written with <Rd> and <Rn> both in the range R0-R7, it is assembled using encoding T1 as though `ORR<c> <Rd>, <Rn>` had been written.

To prevent either of these happening, use the .W qualifier.

The pre-UAL syntax `ORR<c>S` is equivalent to `ORRS<c>`.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    (shifted, carry) = Shift_C(R[m], shift_t, shift_n, APSR.C);
    result = R[n] OR shifted;
    if d == 15 then          // Can only occur for ARM encoding
        ALUWritePC(result);  // setflags is always FALSE here
    else
        R[d] = result;
        if setflags then
            APSR.N = result<31>;
            APSR.Z = IsZeroBit(result);
            APSR.C = carry;
            // APSR.V unchanged
```

Exceptions

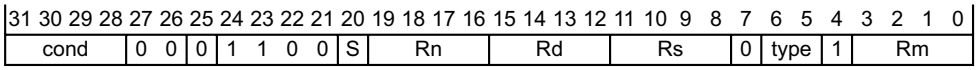
None.

A8.8.124 ORR (register-shifted register)

Bitwise OR (register-shifted register) performs a bitwise (inclusive) OR of a register value and a register-shifted register value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

Encoding A1 ARMv4*, ARMv5T*, ARMv6*, ARMv7

```
ORR{S}<c> <Rd>, <Rn>, <Rm>, <type> <Rs>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  s = UInt(Rs);
setflags = (S == '1');  shift_t = DecodeRegShift(type);
if d == 15 || n == 15 || m == 15 || s == 15 then UNPREDICTABLE;
```

Assembler syntax

```
ORR{S}{<c>}{<q>}  {<Rd>,} <Rn>, <Rm>, <type>  <Rs>
```

where:

S — If S is present, the instruction updates the flags. Otherwise, the flags are not updated.

<c>, <q> — See *Standard assembler syntax fields* on page A8-287.

<Rd> — The destination register.

<Rn> — The first operand register.

<Rm> — The register that is shifted and used as the second operand.

<type> — The type of shift to apply to the value read from <Rm>. It must be one of:

- ASR — Arithmetic shift right, encoded as type = 0b10.
- LSL — Logical shift left, encoded as type = 0b00.
- LSR — Logical shift right, encoded as type = 0b01.
- ROR — Rotate right, encoded as type = 0b11.

<Rs> — The register whose bottom byte contains the amount to shift by.

The pre-UAL syntax ORR<c>S is equivalent to ORRS<c>.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shift_n = UInt(R[s]<7:0>);
    (shifted, carry) = Shift_C(R[m], shift_t, shift_n, APSR.C);
    result = R[n] OR shifted;
    R[d] = result;
    if setflags then
        APSR.N = result<31>;
        APSR.Z = IsZeroBit(result);
        APSR.C = carry;
        // APSR.V unchanged
```

Exceptions

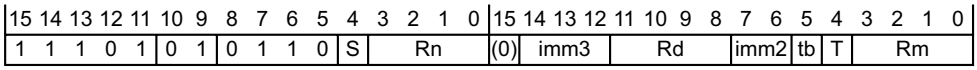
None.

A8.8.125 PKH

Pack Halfword combines one halfword of its first operand with the other halfword of its shifted second operand.

Encoding T1 ARMv6T2, ARMv7

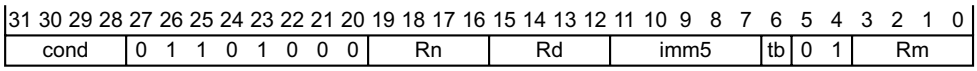
```
PKHBT<c> <Rd>, <Rn>, <Rm>{, LSL #<imm>}
PKHTB<c> <Rd>, <Rn>, <Rm>{, ASR #<imm>}
```



```
if S == '1' || T == '1' then UNDEFINED;
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  tbform = (tb == '1');
(shift_t, shift_n) = DecodeImmShift(tb:'0', imm3:imm2);
if d IN {13,15} || n IN {13,15} || m IN {13,15} then UNPREDICTABLE;
```

Encoding A1 ARMv6*, ARMv7

```
PKHBT<c> <Rd>, <Rn>, <Rm>{, LSL #<imm>}
PKHTB<c> <Rd>, <Rn>, <Rm>{, ASR #<imm>}
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  tbform = (tb == '1');
(shift_t, shift_n) = DecodeImmShift(tb:'0', imm5);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE;
```

Assembler syntax

```
PKHBT{<c>}{<q>}  {<Rd>,} <Rn>, <Rm> {, LSL #<imm>}      tbform == FALSE
PKHTB{<c>}{<q>}  {<Rd>,} <Rn>, <Rm> {, ASR #<imm>}      tbform == TRUE
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287.

`<Rd>` The destination register.

`<Rn>` The first operand register.

`<Rm>` The register that is optionally shifted and used as the second operand.

`<imm>` The shift to apply to the value read from `<Rm>`, encoded in imm3:imm2 for encoding T1 and imm5 for encoding A1.

For `PKHBT`, it is one of:

omitted No shift, encoded as `0b00000`.

1-31 Left shift by specified number of bits, encoded as a binary number.

For `PKHTB`, it is one of:

omitted Instruction is a pseudo-instruction and is assembled as though `PKHBT{<c>}{<q>} <Rd>, <Rm>, <Rn>` had been written.

1-32 Arithmetic right shift by specified number of bits. A shift by 32 bits is encoded as `0b00000`. Other shift amounts are encoded as binary numbers.

Note

An assembler can permit `<imm>` = 0 to mean the same thing as omitting the shift, but this is not standard UAL and must not be used for disassembly.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    operand2 = Shift(R[m], shift_t, shift_n, APSR.C);  // APSR.C ignored
    R[d]<15:0>  = if tbform then operand2<15:0> else R[n]<15:0>;
    R[d]<31:16> = if tbform then R[n]<31:16>    else operand2<31:16>;
```

Exceptions

None.

A8.8.126 PLD, PLDW (immediate)

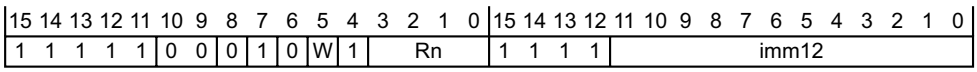
Preload Data signals the memory system that data memory accesses from a specified address are likely in the near future. The memory system can respond by taking actions that are expected to speed up the memory accesses when they do occur, such as pre-loading the cache line containing the specified address into the data cache.

On an architecture variant that includes both the PLD and PLDW instructions, the PLD instruction signals that the likely memory access is a read, and the PLDW instruction signals that it is a write.

The effect of a PLD or PLDW instruction is IMPLEMENTATION DEFINED. For more information, see *Preloading caches* on page A3-157 and *Behavior of Preload Data (PLD, PLDW) and Preload Instruction (PLI) with caches* on page B2-1269.

Encoding T1 ARMv6T2, ARMv7 for PLD
ARMv7 with MP Extensions for PLDW

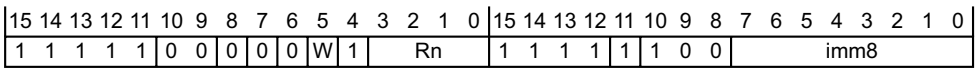
```
PLD{W}<c> [<Rn>, #<imm12>]
```



```
if Rn == '1111' then SEE PLD (literal);
n = UInt(Rn);  imm32 = ZeroExtend(imm12, 32);  add = TRUE;  is_pldw = (W == '1');
```

Encoding T2 ARMv6T2, ARMv7 for PLD
ARMv7 with MP Extensions for PLDW

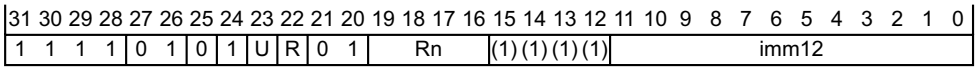
```
PLD{W}<c> [<Rn>, #-<imm8>]
```



```
if Rn == '1111' then SEE PLD (literal);
n = UInt(Rn);  imm32 = ZeroExtend(imm8, 32);  add = FALSE;  is_pldw = (W == '1');
```

Encoding A1 ARMv5TE*, ARMv6*, ARMv7 for PLD
ARMv7 with MP Extensions for PLDW

```
PLD{W} [<Rn>, #+/-<imm12>]
```



```
if Rn == '1111' then SEE PLD (literal);
n = UInt(Rn);  imm32 = ZeroExtend(imm12, 32);  add = (U == '1');  is_pldw = (R == '0');
```

Assembler syntax

```
PLD{W}{<c>}{<q>}  [<Rn> {, #+/-<imm>}]
```

where:

`W` If specified, selects PLDW, encoded as W = 1 in Thumb encodings and R = 0 in ARM encodings. If omitted, selects PLD, encoded as W = 0 in Thumb encodings and R = 1 in ARM encodings.

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287. An ARM `PLD` or `PLDW` instruction must be unconditional.

`<Rn>` The base register. The SP can be used. For PC use in the `PLD` instruction, see *PLD (literal)* on page A8-526.

`+/-` Is + or omitted to indicate that the immediate offset is added to the base register value (`add == TRUE`), or – to indicate that the offset is to be subtracted (`add == FALSE`). Different instructions are generated for `#0` and `#-0`.

`<imm>` The immediate offset used for forming the address. This offset can be omitted, meaning an offset of 0. Values are:

Encoding T1, A1 any value in the range 0-4095

Encoding T2 any value in the range 0-255.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    address = if add then (R[n] + imm32) else (R[n] - imm32);
    if is_pldw then
        Hint_PreloadDataForWrite(address);
    else
        Hint_PreloadData(address);
```

Exceptions

None.

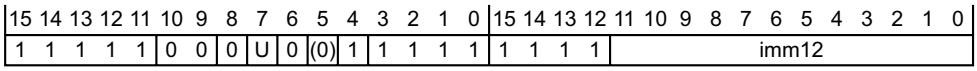
A8.8.127 PLD (literal)

Preload Data signals the memory system that data memory accesses from a specified address are likely in the near future. The memory system can respond by taking actions that are expected to speed up the memory accesses when they do occur, such as pre-loading the cache line containing the specified address into the data cache.

The effect of a PLD instruction is IMPLEMENTATION DEFINED. For more information, see *Preloading caches* on page A3-157 and *Behavior of Preload Data (PLD, PLDW) and Preload Instruction (PLI) with caches* on page B2-1269.

Encoding T1 ARMv6T2, ARMv7

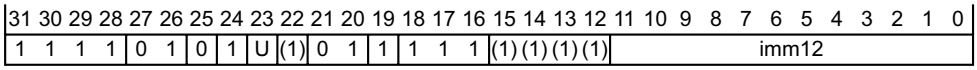
```
PLD<c> <label>
PLD<c> [PC, #-0]                                   Special case
```



```
imm32 = ZeroExtend(imm12, 32);  add = (U == '1');
```

Encoding A1 ARMv5TE*, ARMv6*, ARMv7

```
PLD <label>
PLD [PC, #-0]                                      Special case
```



```
imm32 = ZeroExtend(imm12, 32);  add = (U == '1');
```

Assembler syntax

`PLD{<c>}{<q>}  <label>`	Normal form
`PLD{<c>}{<q>}  [PC, #+/-<imm>]`	Alternative form

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287. An ARM `PLD` instruction must be unconditional.

`<label>` The label of the literal data item that is likely to be accessed in the near future. The assembler calculates the required value of the offset from the `Align(PC, 4)` value of the instruction to this label. The offset must be in the range –4095 to 4095.

If the offset is zero or positive, `imm32` is equal to the offset and `add == TRUE`.

If the offset is negative, `imm32` is equal to minus the offset and `add == FALSE`.

`+/-` Is + or omitted to indicate that the immediate offset is added to the `Align(PC, 4)` value (`add == TRUE`), or – to indicate that the offset is to be subtracted (`add == FALSE`). Different instructions are generated for `#0` and `#-0`.

`<imm>` The immediate offset used for forming the address. Values are in the range 0-4095.

The alternative syntax permits the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see *Use of labels in UAL instruction syntax* on page A4-162.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    address = if add then (Align(PC,4) + imm32) else (Align(PC,4) - imm32);
    Hint_PreloadData(address);
```

Exceptions

None.

A8.8.128 PLD, PLDW (register)

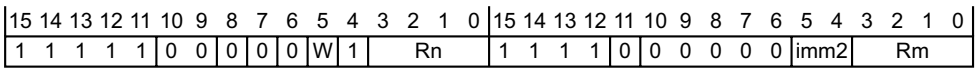
Preload Data signals the memory system that data memory accesses from a specified address are likely in the near future. The memory system can respond by taking actions that are expected to speed up the memory accesses when they do occur, such as pre-loading the cache line containing the specified address into the data cache.

On an architecture variant that includes both the PLD and PLDW instructions, the PLD instruction signals that the likely memory access is a read, and the PLDW instruction signals that it is a write.

The effect of a PLD or PLDW instruction is IMPLEMENTATION DEFINED. For more information, see *Preloading caches* on page A3-157 and *Behavior of Preload Data (PLD, PLDW) and Preload Instruction (PLI) with caches* on page B2-1269.

Encoding T1 ARMv6T2, ARMv7 for PLD
ARMv7 with MP Extensions for PLDW

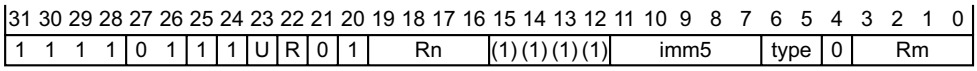
```
PLD{W}<c> [<Rn>, <Rm>{, LSL #<imm2>}]
```



```
if Rn == '1111' then SEE PLD (literal);
n = UInt(Rn);  m = UInt(Rm);  add = TRUE;  is_pldw = (W == '1');
(shift_t, shift_n) = (SRType_LSL, UInt(imm2));
if m IN {13,15} then UNPREDICTABLE;
```

Encoding A1 ARMv5TE*, ARMv6*, ARMv7 for PLD
ARMv7 with MP Extensions for PLDW

```
PLD{W} [<Rn>,+/-<Rm>{, <shift>}]
```



```
n = UInt(Rn);  m = UInt(Rm);  add = (U == '1');  is_pldw = (R == '0');
(shift_t, shift_n) = DecodeImmShift(type, imm5);
if m == 15 || (n == 15 && is_pldw) then UNPREDICTABLE;
```

Assembler syntax

```
PLD[W]{<c>}{<q>}  [<Rn>, +/-<Rm> {, <shift>}]
```

where:

W	If specified, selects PLDW, encoded as W = 1 in Thumb encodings and R = 0 in ARM encodings. If omitted, selects PLD, encoded as W = 0 in Thumb encodings and R = 1 in ARM encodings.
<c>, <q>	See *Standard assembler syntax fields* on page A8-287. An ARM PLD or PLDW instruction must be unconditional.
<Rn>	Is the base register. The SP can be used. The PC can be used in ARM PLD instructions, but not in Thumb PLD instructions or in any PLDW instructions.
+/-	Is + or omitted if the optionally shifted value of <Rm> is to be added to the base register value (add == TRUE), or – if it is to be subtracted (permitted in ARM instructions only, add == FALSE).
<Rm>	Contains the offset that is optionally shifted and applied to the value of <Rn> to form the address.
<shift>	The shift to apply to the value read from <Rm>. If absent, no shift is applied. For encoding T1, <shift> can only be omitted, encoded as imm2 = 0b00, or LSL #<imm> with <imm> = 1, 2, or 3, with <imm> encoded in imm2. For encoding A1, see *Shifts applied to a register* on page A8-291.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    offset = Shift(R[m], shift_t, shift_n, APSR.C);
    address = if add then (R[n] + offset) else (R[n] - offset);
    if is_pldw then
        Hint_PreloadDataForWrite(address);
    else
        Hint_PreloadData(address);
```

Exceptions

None.

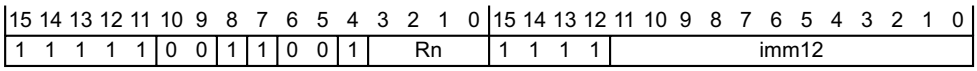
A8.8.129 PLI (immediate, literal)

Preload Instruction signals the memory system that instruction memory accesses from a specified address are likely in the near future. The memory system can respond by taking actions that are expected to speed up the memory accesses when they do occur, such as pre-loading the cache line containing the specified address into the instruction cache.

The effect of a PLI instruction is IMPLEMENTATION DEFINED. For more information, see *Preloading caches* on page A3-157 and *Behavior of Preload Data (PLD, PLDW) and Preload Instruction (PLI) with caches* on page B2-1269.

Encoding T1 ARMv7

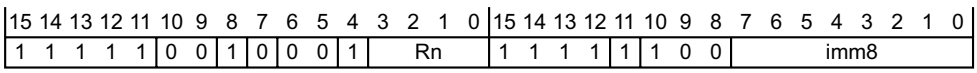
```
PLI<c> [<Rn>, #<imm12>]
```



```
if Rn == '1111' then SEE encoding T3;
n = UInt(Rn);  imm32 = ZeroExtend(imm12, 32);  add = TRUE;
```

Encoding T2 ARMv7

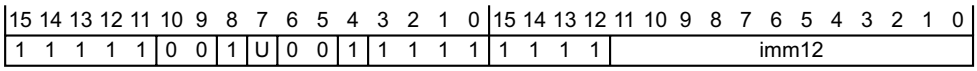
```
PLI<c> [<Rn>, #-<imm8>]
```



```
if Rn == '1111' then SEE encoding T3;
n = UInt(Rn);  imm32 = ZeroExtend(imm8, 32);  add = FALSE;
```

Encoding T3 ARMv7

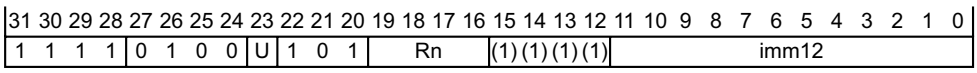
```
PLI<c> <label>
PLI<c> [PC, #-0]                                    Special case
```



```
n = 15;  imm32 = ZeroExtend(imm12, 32);  add = (U == '1');
```

Encoding A1 ARMv7

```
PLI [<Rn>, #+/-<imm12>]
PLI <label>
PLI [PC, #-0]                                       Special case
```



```
n = UInt(Rn);  imm32 = ZeroExtend(imm12, 32);  add = (U == '1');
```

Assembler syntax

`PLI{<c>}{<q>} [<Rn> {, #+/-<imm>}]`	Immediate form
`PLI{<c>}{<q>} <label>`	Normal literal form
`PLI{<c>}{<q>} [PC, #+/-<imm>]`	Alternative literal form

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287. An ARM `PLI` instruction must be unconditional.

`<Rn>` Is the base register. The SP can be used.

`+/-` Is + or omitted to indicate that the immediate offset is added to the base register value (`add == TRUE`), or – to indicate that the offset is to be subtracted (`add == FALSE`). Different instructions are generated for `#0` and `#-0`.

`<imm>` The immediate offset used for forming the address. For the immediate form of the syntax, `<imm>` can be omitted, in which case the `#0` form of the instruction is assembled. Values are:

Encoding T1, T3, A1 any value in the range 0 to 4095

Encoding T2 any value in the range 0 to 255.

`<label>` The label of the instruction that is likely to be accessed in the near future. The assembler calculates the required value of the offset from the `Align(PC, 4)` value of the instruction to this label. The offset must be in the range –4095 to 4095.

If the offset is zero or positive, `imm32` is equal to the offset and `add == TRUE`.

If the offset is negative, `imm32` is equal to minus the offset and `add == FALSE`.

For the literal forms of the instruction, encoding T3 is used, or Rn is encoded as `0b1111` in encoding A1, to indicate that the PC is the base register.

The alternative literal syntax permits the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see *Use of labels in UAL instruction syntax* on page A4-162.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    base = if n == 15 then Align(PC,4) else R[n];
    address = if add then (base + imm32) else (base - imm32);
    Hint_PreloadInstr(address);
```

Exceptions

None.

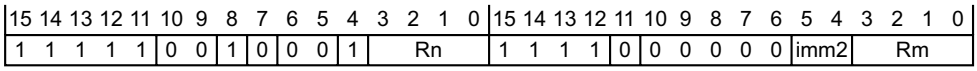
A8.8.130 PLI (register)

Preload Instruction signals the memory system that instruction memory accesses from a specified address are likely in the near future. The memory system can respond by taking actions that are expected to speed up the memory accesses when they do occur, such as pre-loading the cache line containing the specified address into the instruction cache. For more information, see *Behavior of Preload Data (PLD, PLDW) and Preload Instruction (PLI) with caches* on page B2-1269.

The effect of a PLI instruction is IMPLEMENTATION DEFINED. For more information, see *Preloading caches* on page A3-157 and *Behavior of Preload Data (PLD, PLDW) and Preload Instruction (PLI) with caches* on page B2-1269.

Encoding T1 ARMv7

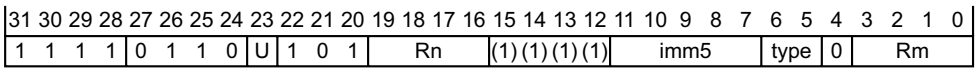
```
PLI<c> [<Rn>, <Rm>{, LSL #<imm2>}]
```



```
if Rn == '1111' then SEE PLI (immediate, literal);
n = UInt(Rn);  m = UInt(Rm);  add = TRUE;
(shift_t, shift_n) = (SRType_LSL, UInt(imm2));
if m IN {13,15} then UNPREDICTABLE;
```

Encoding A1 ARMv7

```
PLI [<Rn>,+/-<Rm>{, <shift>}]
```



```
n = UInt(Rn);  m = UInt(Rm);  add = (U == '1');
(shift_t, shift_n) = DecodeImmShift(type, imm5);
if m == 15 then UNPREDICTABLE;
```

Assembler syntax

```
PLI{<c>}{<q>}  [<Rn>, +/-<Rm> {, <shift>}]
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287. An ARM `PLI` instruction must be unconditional.

`<Rn>` Is the base register. The SP can be used.

`+/-` Is + or omitted if the optionally shifted value of `<Rm>` is to be added to the base register value (`add == TRUE`), or – if it is to be subtracted (permitted in ARM instructions only, `add == FALSE`).

`<Rm>` Contains the offset that is optionally shifted and applied to the value of `<Rn>` to form the address.

`<shift>` The shift to apply to the value read from `<Rm>`. If absent, no shift is applied. For encoding T1, `<shift>` can only be omitted, encoded as imm2 = `0b00`, or `LSL #<imm>` with `<imm>` = 1, 2, or 3, with `<imm>` encoded in imm2. For encoding A1, see *Shifts applied to a register* on page A8-291.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    offset = Shift(R[m], shift_t, shift_n, APSR.C);
    address = if add then (R[n] + offset) else (R[n] - offset);
    Hint_PreloadInstr(address);
```

Exceptions

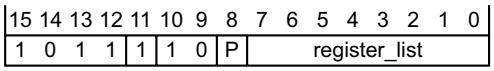
None.

A8.8.131 POP (Thumb)

Pop Multiple Registers loads multiple registers from the stack, loading from consecutive memory locations starting at the address in SP, and updates SP to point just above the loaded data.

Encoding T1 ARMv4T, ARMv5T*, ARMv6*, ARMv7

```
POP<c> <registers>
```

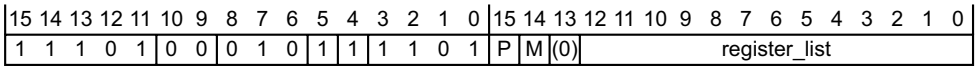


```
registers = P:'0000000':register_list;   UnalignedAllowed = FALSE;
if BitCount(registers) < 1 then UNPREDICTABLE;
if registers<15> == '1' && InITBlock() && !LastInITBlock() then UNPREDICTABLE;
```

Encoding T2 ARMv6T2, ARMv7

```
POP<c>.W <registers>
```

<registers> contains more than one register

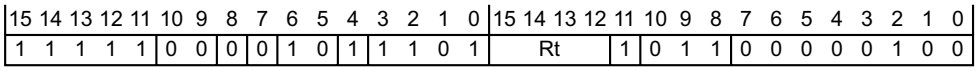


```
registers = P:M:'0':register_list;  UnalignedAllowed = FALSE;
if BitCount(registers) < 2 || (P == '1' && M == '1') then UNPREDICTABLE;
if registers<15> == '1' && InITBlock() && !LastInITBlock() then UNPREDICTABLE;
```

Encoding T3 ARMv6T2, ARMv7

```
POP<c>.W <registers>
```

<registers> contains one register, <Rt>



```
t = UInt(Rt);  registers = Zeros(16);  registers<t> = '1';  UnalignedAllowed = TRUE;
if t == 13 || (t == 15 && InITBlock() && !LastInITBlock()) then UNPREDICTABLE;
```

Assembler syntax

`POP{<c>}{<q>}  <registers>`	Standard syntax
`LDM{<c>}{<q>}  SP!, <registers>`	Equivalent `LDM` syntax

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287.

`<registers>` Is a list of one or more registers to be loaded, separated by commas and surrounded by { and }. The lowest-numbered register is loaded from the lowest memory address, through to the highest-numbered register from the highest memory address. See also *Encoding of lists of ARM core registers* on page A8-295.

If the list contains more than one register, the instruction is assembled to encoding T1 or T2. If the list contains exactly one register, the instruction is assembled to encoding T1 or T3.

The PC can be in the list. If it is, the instruction branches to the address loaded to the PC. In ARMv5T and above, this is an interworking branch, see *Pseudocode details of operations on ARM core registers* on page A2-47. If the PC is in the list:

- the LR must not be in the list
- the instruction must be either outside any IT block, or the last instruction in an IT block.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  NullCheckIfThumbEE(13);
    address = SP;
    for i = 0 to 14
        if registers<i> == '1' then
            R[i] = if UnalignedAllowed then MemU[address,4] else MemA[address,4];
            address = address + 4;
    if registers<15> == '1' then
        if UnalignedAllowed then
            if address<1:0> == '00' then
                LoadWritePC(MemU[address,4]);
            else
                UNPREDICTABLE;
        else
            LoadWritePC(MemA[address,4]);
    if registers<13> == '0' then SP = SP + 4*BitCount(registers);
    if registers<13> == '1' then SP = bits(32) UNKNOWN;
```

Exceptions

Data Abort.

A8.8.132 POP (ARM)

Pop Multiple Registers loads multiple registers from the stack, loading from consecutive memory locations starting at the address in SP, and updates SP to point just above the loaded data.

Encoding A1 ARMv4*, ARMv5T*, ARMv6*, ARMv7

`POP<c> <registers>` `<registers>` contains more than one register

31 30 29 28	27 26 25	24 23 22	21	20	19 18 17 16	15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
cond	1 0 0	0 1 0	1	1	1 1 0 1	register_list

```
if BitCount(register_list) < 2 then SEE LDM / LDMIA / LDMFD;
registers = register_list;  UnalignedAllowed = FALSE;
if registers<13> == '1' && ArchVersion() >= 7 then UNPREDICTABLE;
```

Encoding A2 ARMv4*, ARMv5T*, ARMv6*, ARMv7

`POP<c> <registers>` `<registers>` contains one register, `<Rt>`

31 30 29 28	27 26 25	24	23	22	21	20	19 18 17 16	15 14 13 12	11 10 9 8 7 6 5 4 3 2 1 0
cond	0 1 0	0	1	0	0	1	1 1 0 1	Rt	0 0 0 0 0 0 0 0 0 1 0 0

```
t = UInt(Rt);  registers = Zeros(16);  registers<t> = '1';  UnalignedAllowed = TRUE;
if t == 13 then UNPREDICTABLE;
```

Assembler syntax

`POP{<c>}{<q>}  <registers>`	Standard syntax
`LDM{<c>}{<q>}  SP!, <registers>`	Equivalent `LDM` syntax

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287.

`<registers>` Is a list of one or more registers to be loaded, separated by commas and surrounded by { and }. The lowest-numbered register is loaded from the lowest memory address, through to the highest-numbered register from the highest memory address. See also *Encoding of lists of ARM core registers* on page A8-295.

If the list contains more than one register, the instruction is assembled to encoding A1. If the list contains exactly one register, the instruction is assembled to encoding A2.

The SP can only be in the list before ARMv7. ARM deprecates any use of ARM instructions that include the SP, and the value of the SP after such an instruction is UNKNOWN.

The PC can be in the list. If it is, the instruction branches to the address loaded to the PC. In ARMv5T and above, this is an interworking branch, see *Pseudocode details of operations on ARM core registers* on page A2-47.

ARM deprecates the use of this instruction with both the LR and the PC in the list.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  NullCheckIfThumbEE(13);
    address = SP;
    for i = 0 to 14
        if registers<i> == '1' then
            R[i] = if UnalignedAllowed then MemU[address,4] else MemA[address,4];
            address = address + 4;
    if registers<15> == '1' then
        if UnalignedAllowed then
            if address<1:0> == '00' then
                LoadWritePC(MemU[address,4]);
            else
                UNPREDICTABLE;
        else
            LoadWritePC(MemA[address,4]);
    if registers<13> == '0' then SP = SP + 4*BitCount(registers);
    if registers<13> == '1' then SP = bits(32) UNKNOWN;
```

Exceptions

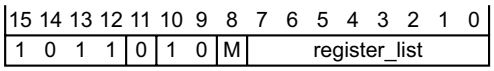
Data Abort.

A8.8.133 PUSH

Push Multiple Registers stores multiple registers to the stack, storing to consecutive memory locations ending just below the address in SP, and updates SP to point to the start of the stored data.

Encoding T1 ARMv4T, ARMv5T*, ARMv6*, ARMv7

```
PUSH<c> <registers>
```

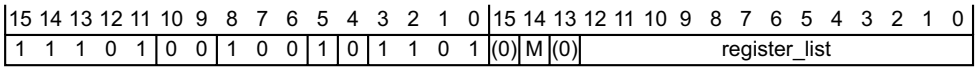


```
registers = '0':M:'000000':register_list;  UnalignedAllowed = FALSE;
if BitCount(registers) < 1 then UNPREDICTABLE;
```

Encoding T2 ARMv6T2, ARMv7

```
PUSH<c>.W <registers>
```

<registers> contains more than one register

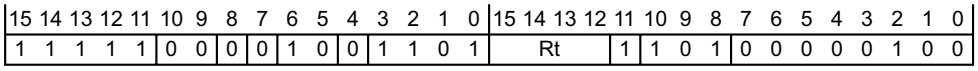


```
registers = '0':M:'0':register_list;  UnalignedAllowed = FALSE;
if BitCount(registers) < 2 then UNPREDICTABLE;
```

Encoding T3 ARMv6T2, ARMv7

```
PUSH<c>.W <registers>
```

<registers> contains one register, <Rt>

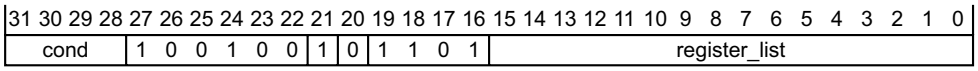


```
t = UInt(Rt);  registers = Zeros(16);  registers<t> = '1';  UnalignedAllowed = TRUE;
if t IN {13,15} then UNPREDICTABLE;
```

Encoding A1 ARMv4*, ARMv5T*, ARMv6*, ARMv7

```
PUSH<c> <registers>
```

<registers> contains more than one register

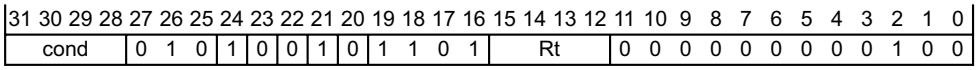


```
if BitCount(register_list) < 2 then SEE STMDB / STMFD;
registers = register_list;  UnalignedAllowed = FALSE;
```

Encoding A2 ARMv4*, ARMv5T*, ARMv6*, ARMv7

```
PUSH<c> <registers>
```

<registers> contains one register, <Rt>



```
t = UInt(Rt);  registers = Zeros(16);  registers<t> = '1';  UnalignedAllowed = TRUE;
if t == 13 then UNPREDICTABLE;
```

Assembler syntax

`PUSH{<c>}{<q>}  <registers>`	Standard syntax
`STMDB{<c>}{<q>}  SP!, <registers>`	Equivalent `STM` syntax

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287.

`<registers>` Is a list of one or more registers to be stored, separated by commas and surrounded by { and }. The lowest-numbered register is stored to the lowest memory address, through to the highest-numbered register to the highest memory address. See also *Encoding of lists of ARM core registers* on page A8-295.

If the list contains more than one register, the instruction is assembled to encoding T1, T2, or A1. If the list contains exactly one register, the instruction is assembled to encoding T1, T3, or A2.

The SP and PC can be in the list in ARM instructions, but not in Thumb instructions. However:

- ARM deprecates the use of ARM instructions that include the PC in the list
- if the SP is in the list, and it is not the lowest-numbered register in the list, the instruction stores an UNKNOWN value for the SP.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  NullCheckIfThumbEE(13);
    address = SP - 4*BitCount(registers);
    for i = 0 to 14
        if registers<i> == '1' then
            if i == 13 && i != LowestSetBit(registers) then  // Only possible for encoding A1
                MemA[address,4] = bits(32) UNKNOWN;
            else
                if UnalignedAllowed then
                    MemU[address,4] = R[i];
                else
                    MemA[address,4] = R[i];
            address = address + 4;
    if registers<15> == '1' then  // Only possible for encoding A1 or A2
        if UnalignedAllowed then
            MemU[address,4] = PCStoreValue();
        else
            MemA[address,4] = PCStoreValue();
    SP = SP - 4*BitCount(registers);
```

Exceptions

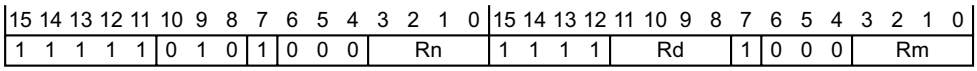
Data Abort.

A8.8.134 QADD

Saturating Add adds two register values, saturates the result to the 32-bit signed integer range -2^{31} to $(2^{31} - 1)$, and writes the result to the destination register. If saturation occurs, it sets the Q flag in the APSR.

Encoding T1 ARMv6T2, ARMv7

```
QADD<c> <Rd>, <Rm>, <Rn>
```



15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	1	0	1	0	1	0	0	0	Rn				1	1	1	1	Rd				1	0	0	0	Rm			

```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);
if d IN {13,15} || n IN {13,15} || m IN {13,15} then UNPREDICTABLE;
```

if imm5 == '00000' then SEE RRX;
d = UInt(Rd);  m = UInt(Rm);  setflags = (S == '1');
(-, shift_n) = DecodeImmShift('11', imm5);
```

Assembler syntax

```
ROR{S}{<c>}{<q>}  {<Rd>,} <Rm>, #<imm>
```

where:

S — If S is present, the instruction updates the flags. Otherwise, the flags are not updated.

<c>, <q> — See *Standard assembler syntax fields* on page A8-287.

<Rd> — The destination register.

In ARM instructions, if S is not specified and <Rd> is the PC, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode details of operations on ARM core registers* on page A2-47.

Note

Before ARMv7, this was a simple branch.

<Rm> — The first operand register. The PC can be used in ARM instructions.

<imm> — The shift amount, in the range 1 to 31. See *Shifts applied to a register* on page A8-291.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    (result, carry) = Shift_C(R[m], SRType_ROR, shift_n, APSR.C);
    if d == 15 then          // Can only occur for ARM encoding
        ALUWritePC(result);  // setflags is always FALSE here
    else
        R[d] = result;
        if setflags then
            APSR.N = result<31>;
            APSR.Z = IsZeroBit(result);
            APSR.C = carry;
            // APSR.V unchanged
```

Exceptions

None.

A8.8.150 ROR (register)

Rotate Right (register) provides the value of the contents of a register rotated by a variable number of bits. The bits that are rotated off the right end are inserted into the vacated bit positions on the left. The variable number of bits is read from the bottom byte of a register. It can optionally update the condition flags based on the result.

where:

S — If S is present, the instruction updates the flags. Otherwise, the flags are not updated.

<c>, <q> — See *Standard assembler syntax fields* on page A8-287.

<Rd> — The destination register. If S is specified and <Rd> is the PC, see *SUBS PC, LR (Thumb)* on page B9-2008 or *SUBS PC, LR and related instructions (ARM)* on page B9-2010.

In ARM instructions, if S is not specified and <Rd> is the PC, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode details of operations on ARM core registers* on page A2-47.

Note

Before ARMv7, this was a simple branch.

<Rn> — The first operand register. The PC can be used in ARM instructions.

<Rm> — The register that is optionally shifted and used as the second operand. The PC can be used in ARM instructions.

<shift> — The shift to apply to the value read from <Rm>. If omitted, no shift is applied. *Shifts applied to a register* on page A8-291 describes the shifts and how they are encoded.

The pre-UAL syntax RSB<c>S is equivalent to RSBS<c>.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shifted = Shift(R[m], shift_t, shift_n, APSR.C);
    (result, carry, overflow) = AddWithCarry(NOT(R[n]), shifted, '1');
    if d == 15 then          // Can only occur for ARM encoding
        ALUWritePC(result);  // setflags is always FALSE here
    else
        R[d] = result;
        if setflags then
            APSR.N = result<31>;
            APSR.Z = IsZeroBit(result);
            APSR.C = carry;
            APSR.V = overflow;
```

Exceptions

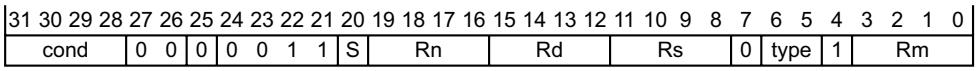
None.

A8.8.154 RSB (register-shifted register)

Reverse Subtract (register-shifted register) subtracts a register value from a register-shifted register value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

Encoding A1 ARMv4*, ARMv5T*, ARMv6*, ARMv7

```
RSB{S}<c> <Rd>, <Rn>, <Rm>, <type> <Rs>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  s = UInt(Rs);
setflags = (S == '1');  shift_t = DecodeRegShift(type);
if d == 15 || n == 15 || m == 15 || s == 15 then UNPREDICTABLE;
```

Assembler syntax

```
RSB{S}{<c>}{<q>}  {<Rd>,} <Rn>, <Rm>, <type>  <Rs>
```

where:

S — If S is present, the instruction updates the flags. Otherwise, the flags are not updated.

<c>, <q> — See *Standard assembler syntax fields* on page A8-287.

<Rd> — The destination register.

<Rn> — The first operand register.

<Rm> — The register that is shifted and used as the second operand.

<type> — The type of shift to apply to the value read from <Rm>. It must be one of:

- ASR — Arithmetic shift right, encoded as type = 0b10.
- LSL — Logical shift left, encoded as type = 0b00.
- LSR — Logical shift right, encoded as type = 0b01.
- ROR — Rotate right, encoded as type = 0b11.

<Rs> — The register whose bottom byte contains the amount to shift by.

The pre-UAL syntax RSB<c>S is equivalent to RSBS<c>.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shift_n = UInt(R[s]<7:0>);
    shifted = Shift(R[m], shift_t, shift_n, APSR.C);
    (result, carry, overflow) = AddWithCarry(NOT(R[n]), shifted, '1');
    R[d] = result;
    if setflags then
        APSR.N = result<31>;
        APSR.Z = IsZeroBit(result);
        APSR.C = carry;
        APSR.V = overflow;
```

Exceptions

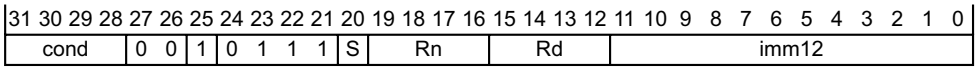
None.

A8.8.155 RSC (immediate)

Reverse Subtract with Carry (immediate) subtracts a register value and the value of NOT (Carry flag) from an immediate value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

Encoding A1 ARMv4*, ARMv5T*, ARMv6*, ARMv7

```
RSC{S}<c> <Rd>, <Rn>, #<const>
```



```
if Rd == '1111' && S == '1' then SEE SUBS PC, LR and related instructions;
d = UInt(Rd);  n = UInt(Rn);  setflags = (S == '1');  imm32 = ARMExpandImm(imm12);
```

Assembler syntax

```
RSC{S}{<c>}{<q>}  {<Rd>,} <Rn>, #<const>
```

where:

S	If S is present, the instruction updates the flags. Otherwise, the flags are not updated.
<c>, <q>	See *Standard assembler syntax fields* on page A8-287.
<Rd>	The destination register. If S is specified and <Rd> is the PC, see *SUBS PC, LR (Thumb)* on page B9-2008 or *SUBS PC, LR and related instructions (ARM)* on page B9-2010.
<Rn>	The first operand register. The PC can be used.
<const>	The immediate value that the value obtained from <Rn> is to be subtracted from. See *Modified immediate constants in ARM instructions* on page A5-200 for the range of values.

The pre-UAL syntax RSC<c>S is equivalent to RSCS<c>.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    (result, carry, overflow) = AddWithCarry(NOT(R[n]), imm32, APSR.C);
    if d == 15 then
        ALUWritePC(result);  // setflags is always FALSE here
    else
        R[d] = result;
        if setflags then
            APSR.N = result<31>;
            APSR.Z = IsZeroBit(result);
            APSR.C = carry;
            APSR.V = overflow;
```

Exceptions

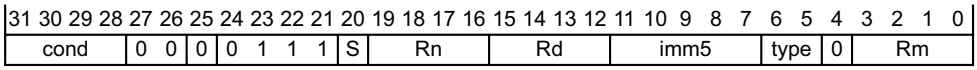
None.

A8.8.156 RSC (register)

Reverse Subtract with Carry (register) subtracts a register value and the value of NOT (Carry flag) from an optionally-shifted register value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

Encoding A1 ARMv4*, ARMv5T*, ARMv6*, ARMv7

```
RSC{S}<c> <Rd>, <Rn>, <Rm>{, <shift>}
```



31 30 29 28	27 26	25	24 23 22 21	20	19 18 17 16	15 14 13 12	11 10 9 8 7	6 5	4	3 2 1 0
cond	0 0	0	0 1 1 1	S	Rn	Rd	imm5	type	0	Rm

```
if Rd == '1111' && S == '1' then SEE SUBS PC, LR and related instructions;
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  setflags = (S == '1');
(shift_t, shift_n) = DecodeImmShift(type, imm5);
```

Assembler syntax

```
RSC{S}{<c>}{<q>}  {<Rd>,} <Rn>, <Rm> {, <shift>}
```

where:

S	If S is present, the instruction updates the flags. Otherwise, the flags are not updated.
<c>, <q>	See *Standard assembler syntax fields* on page A8-287.
<Rd>	The destination register. If S is specified and <Rd> is the PC, see *SUBS PC, LR (Thumb)* on page B9-2008 or *SUBS PC, LR and related instructions (ARM)* on page B9-2010. In ARM instructions, if S is not specified and <Rd> is the PC, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode details of operations on ARM core registers* on page A2-47. **Note** Before ARMv7, this was a simple branch.
<Rn>	The first operand register. The PC can be used.
<Rm>	The register that is optionally shifted and used as the second operand. The PC can be used.
<shift>	The shift to apply to the value read from <Rm>. If omitted, no shift is applied. *Shifts applied to a register* on page A8-291 describes the shifts and how they are encoded.

The pre-UAL syntax RSC<c>S is equivalent to RSCS<c>.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shifted = Shift(R[m], shift_t, shift_n, APSR.C);
    (result, carry, overflow) = AddWithCarry(NOT(R[n]), shifted, APSR.C);
    if d == 15 then
        ALUWritePC(result);  // setflags is always FALSE here
    else
        R[d] = result;
        if setflags then
            APSR.N = result<31>;
            APSR.Z = IsZeroBit(result);
            APSR.C = carry;
            APSR.V = overflow;
```

Exceptions

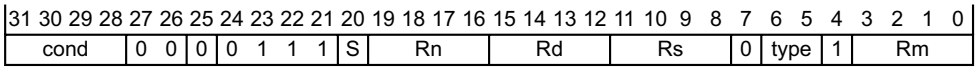
None.

A8.8.157 RSC (register-shifted register)

Reverse Subtract (register-shifted register) subtracts a register value and the value of NOT (Carry flag) from a register-shifted register value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

Encoding A1 ARMv4*, ARMv5T*, ARMv6*, ARMv7

```
RSC{S}<c> <Rd>, <Rn>, <Rm>, <type> <Rs>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  s = UInt(Rs);
setflags = (S == '1');  shift_t = DecodeRegShift(type);
if d == 15 || n == 15 || m == 15 || s == 15 then UNPREDICTABLE;
```

Assembler syntax

```
RSC{S}{<c>}{<q>}  {<Rd>,} <Rn>, <Rm>, <type>  <Rs>
```

where:

S — If S is present, the instruction updates the flags. Otherwise, the flags are not updated.

<c>, <q> — See *Standard assembler syntax fields* on page A8-287.

<Rd> — The destination register.

<Rn> — The first operand register.

<Rm> — The register that is shifted and used as the second operand.

<type> — The type of shift to apply to the value read from <Rm>. It must be one of:

- ASR — Arithmetic shift right, encoded as type = 0b10.
- LSL — Logical shift left, encoded as type = 0b00.
- LSR — Logical shift right, encoded as type = 0b01.
- ROR — Rotate right, encoded as type = 0b11.

<Rs> — The register whose bottom byte contains the amount to shift by.

The pre-UAL syntax RSC<c>S is equivalent to RSCS<c>.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shift_n = UInt(R[s]<7:0>);
    shifted = Shift(R[m], shift_t, shift_n, APSR.C);
    (result, carry, overflow) = AddWithCarry(NOT(R[n]), shifted, APSR.C);
    R[d] = result;
    if setflags then
        APSR.N = result<31>;
        APSR.Z = IsZeroBit(result);
        APSR.C = carry;
        APSR.V = overflow;
```

Exceptions

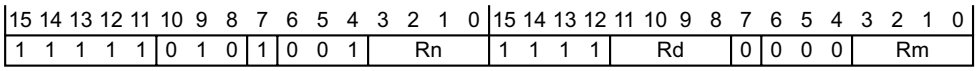
None.

A8.8.158 SADD16

Signed Add 16 performs two 16-bit signed integer additions, and writes the results to the destination register. It sets the APSR.GE bits according to the results of the additions.

Encoding T1 ARMv6T2, ARMv7

```
SADD16<c> <Rd>, <Rn>, <Rm>
```



15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

```

Exceptions

None.

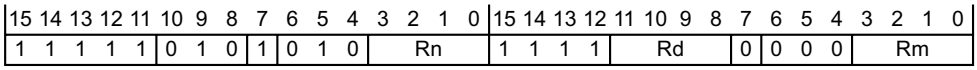
A8.8.160 SASX

Signed Add and Subtract with Exchange exchanges the two halfwords of the second operand, performs one 16-bit integer addition and one 16-bit subtraction, and writes the results to the destination register. It sets the APSR.GE bits according to the results.

Encoding T1 ARMv6T2, ARMv7

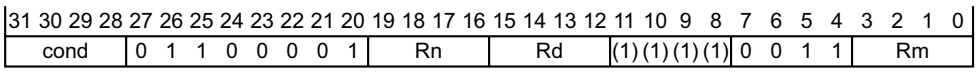
```
SASX<c> <Rd>, <Rn>, <Rm>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);
if d IN {13,15} || n IN {13,15} || m IN {13,15} then UNPREDICTABLE;
```

Encoding A1 ARMv6*, ARMv7

```
SASX<c> <Rd>, <Rn>, <Rm>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE;
```

Assembler syntax

```
SASX{<c>}{<q>}  {<Rd>,} <Rn>, <Rm>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287.

`<Rd>` The destination register.

`<Rn>` The first operand register.

`<Rm>` The second operand register.

The pre-UAL syntax `SADDSUBX<c>` is equivalent to `SASX<c>`.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    diff = SInt(R[n]<15:0>) - SInt(R[m]<31:16>);
    sum  = SInt(R[n]<31:16>) + SInt(R[m]<15:0>);
    R[d]<15:0>  = diff<15:0>;
    R[d]<31:16> = sum<15:0>;
    APSR.GE<1:0> = if diff >= 0 then '11' else '00';
    APSR.GE<3:2> = if sum  >= 0 then '11' else '00';
```

Exceptions

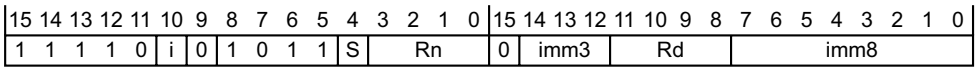
None.

A8.8.161 SBC (immediate)

Subtract with Carry (immediate) subtracts an immediate value and the value of NOT (Carry flag) from a register value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

Encoding T1 ARMv6T2, ARMv7

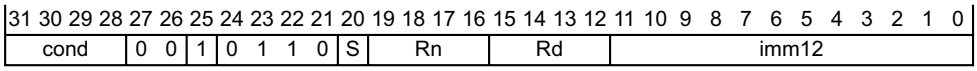
```
SBC{S}<c> <Rd>, <Rn>, #<const>
```



```
d = UInt(Rd);  n = UInt(Rn);  setflags = (S == '1');  imm32 = ThumbExpandImm(i:imm3:imm8);
if d IN {13,15} || n IN {13,15} then UNPREDICTABLE;
```

Encoding A1 ARMv4*, ARMv5T*, ARMv6*, ARMv7

```
SBC{S}<c> <Rd>, <Rn>, #<const>
```



```
if Rd == '1111' && S == '1' then SEE SUBS PC, LR and related instructions;
d = UInt(Rd);  n = UInt(Rn);  setflags = (S == '1');  imm32 = ARMExpandImm(imm12);
```

Assembler syntax

```
SBC{S}{<c>}{<q>}  {<Rd>,} <Rn>, #<const>
```

where:

S — If S is present, the instruction updates the flags. Otherwise, the flags are not updated.

<c>, <q> — See *Standard assembler syntax fields* on page A8-287.

<Rd> — The destination register. If S is specified and <Rd> is the PC, see *SUBS PC, LR (Thumb)* on page B9-2008 or *SUBS PC, LR and related instructions (ARM)* on page B9-2010.

In ARM instructions, if S is not specified and <Rd> is the PC, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode details of operations on ARM core registers* on page A2-47.

Note

Before ARMv7, this was a simple branch.

<Rn> — The first operand register. The PC can be used in ARM instructions.

<const> — The immediate value to be subtracted from the value obtained from <Rn>. See *Modified immediate constants in Thumb instructions* on page A6-232 or *Modified immediate constants in ARM instructions* on page A5-200 for the range of values.

The pre-UAL syntax SBC<c>S is equivalent to SBCS<c>.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    (result, carry, overflow) = AddWithCarry(R[n], NOT(imm32), APSR.C);
    if d == 15 then          // Can only occur for ARM encoding
        ALUWritePC(result);  // setflags is always FALSE here
    else
        R[d] = result;
        if setflags then
            APSR.N = result<31>;
            APSR.Z = IsZeroBit(result);
            APSR.C = carry;
            APSR.V = overflow;
```

Exceptions

None.

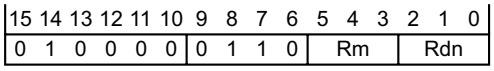
A8.8.162 SBC (register)

Subtract with Carry (register) subtracts an optionally-shifted register value and the value of NOT (Carry flag) from a register value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

Encoding T1 ARMv4T, ARMv5T*, ARMv6*, ARMv7

`SBCS <Rdn>, <Rm>` Outside IT block.

`SBC<c> <Rdn>, <Rm>` Inside IT block.



```
d = UInt(Rdn);  n = UInt(Rdn);  m = UInt(Rm);  setflags = !InITBlock();

```

where:

S — If S is present, the instruction updates the flags. Otherwise, the flags are not updated.

<c>, <q> — See *Standard assembler syntax fields* on page A8-287.

<Rd> — The destination register. If S is specified and <Rd> is the PC, see *SUBS PC, LR (Thumb)* on page B9-2008 or *SUBS PC, LR and related instructions (ARM)* on page B9-2010.

In ARM instructions, if S is not specified and <Rd> is the PC, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode details of operations on ARM core registers* on page A2-47.

Note

Before ARMv7, this was a simple branch.

<Rn> — The first operand register. The PC can be used in ARM instructions.

<Rm> — The register that is optionally shifted and used as the second operand. The PC can be used in ARM instructions.

<shift> — The shift to apply to the value read from <Rm>. If present, encoding T1 is not permitted. If absent, no shift is applied and all encodings are permitted. *Shifts applied to a register* on page A8-291 describes the shifts and how they are encoded.

The pre-UAL syntax SBC<c>S is equivalent to SBCS<c>.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shifted = Shift(R[m], shift_t, shift_n, APSR.C);
    (result, carry, overflow) = AddWithCarry(R[n], NOT(shifted), APSR.C);
    if d == 15 then          // Can only occur for ARM encoding
        ALUWritePC(result);  // setflags is always FALSE here
    else
        R[d] = result;
        if setflags then
            APSR.N = result<31>;
            APSR.Z = IsZeroBit(result);
            APSR.C = carry;
            APSR.V = overflow;
```

Exceptions

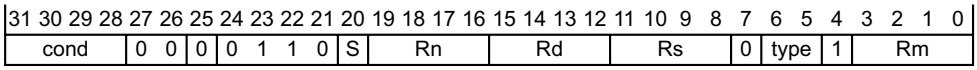
None.

A8.8.163 SBC (register-shifted register)

Subtract with Carry (register-shifted register) subtracts a register-shifted register value and the value of NOT (Carry flag) from a register value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

Encoding A1 ARMv4*, ARMv5T*, ARMv6*, ARMv7

```
SBC{S}<c> <Rd>, <Rn>, <Rm>, <type> <Rs>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  s = UInt(Rs);
setflags = (S == '1');  shift_t = DecodeRegShift(type);
if d == 15 || n == 15 || m == 15 || s == 15 then UNPREDICTABLE;
```

Assembler syntax

```
SBC{S}{<c>}{<q>}  {<Rd>,} <Rn>, <Rm>, <type>  <Rs>
```

where:

S — If S is present, the instruction updates the flags. Otherwise, the flags are not updated.

<c>, <q> — See *Standard assembler syntax fields* on page A8-287.

<Rd> — The destination register.

<Rn> — The first operand register.

<Rm> — The register that is shifted and used as the second operand.

<type> — The type of shift to apply to the value read from <Rm>. It must be one of:

- ASR — Arithmetic shift right, encoded as type = 0b10.
- LSL — Logical shift left, encoded as type = 0b00.
- LSR — Logical shift right, encoded as type = 0b01.
- ROR — Rotate right, encoded as type = 0b11.

<Rs> — The register whose bottom byte contains the amount to shift by.

The pre-UAL syntax SBC<c>S is equivalent to SBCS<c>.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shift_n = UInt(R[s]<7:0>);
    shifted = Shift(R[m], shift_t, shift_n, APSR.C);
    (result, carry, overflow) = AddWithCarry(R[n], NOT(shifted), APSR.C);
    R[d] = result;
    if setflags then
        APSR.N = result<31>;
        APSR.Z = IsZeroBit(result);
        APSR.C = carry;
        APSR.V = overflow;
```

Exceptions

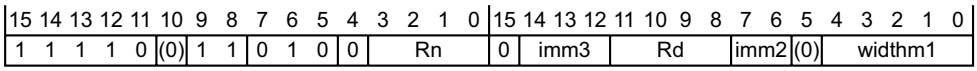
None.

A8.8.164 SBFX

Signed Bit Field Extract extracts any number of adjacent bits at any position from a register, sign-extends them to 32 bits, and writes the result to the destination register.

Encoding T1 ARMv6T2, ARMv7

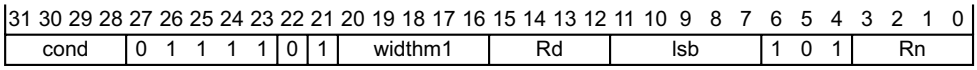
```
SBFX<c> <Rd>, <Rn>, #<lsb>, #<width>
```



```
d = UInt(Rd);  n = UInt(Rn);
lsbit = UInt(imm3:imm2);  widthminus1 = UInt(widthm1);
if d IN {13,15} || n IN {13,15} then UNPREDICTABLE;
```

Encoding A1 ARMv6T2, ARMv7

```
SBFX<c> <Rd>, <Rn>, #<lsb>, #<width>
```



```
d = UInt(Rd);  n = UInt(Rn);
lsbit = UInt(lsb);  widthminus1 = UInt(widthm1);
if d == 15 || n == 15 then UNPREDICTABLE;
```

Assembler syntax

```
SBFX{<c>}{<q>}  <Rd>, <Rn>, #<lsb>, #<width>
```

where:

`<c>, <q>`	See *Standard assembler syntax fields* on page A8-287.
`<Rd>`	The destination register.
`<Rn>`	The first operand register.
`<lsb>`	is the bit number of the least significant bit in the field, in the range 0-31. This determines the required value of `lsbit`.
`<width>`	is the width of the field, in the range 1 to 32-`<lsb>`. The required value of `widthminus1` is `<width>`-1.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    msbit = lsbit + widthminus1;
    if msbit <= 31 then
        R[d] = SignExtend(R[n]<msbit:lsbit>, 32);
    else
        UNPREDICTABLE;
```

Exceptions

None.

A8.8.165 SDIV

Signed Divide divides a 32-bit signed integer register value by a 32-bit signed integer register value, and writes the result to the destination register. The condition flags are not affected.

See *ARMv7 implementation requirements and options for the divide instructions* on page A4-172 for more information about this instruction.

Encoding T1 ARMv7-R, ARMv7VE, otherwise OPTIONAL in ARMv7-A

```

```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE;
```

Assembler syntax

```
SDIV{<c>}{<q>}  {<Rd>,} <Rn>, <Rm>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287.

`<Rd>` The destination register.

`<Rn>` The register that contains the dividend.

`<Rm>` The register that contains the divisor.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if SInt(R[m]) == 0 then
        if IntegerZeroDivideTrappingEnabled() then
            GenerateIntegerZeroDivide();
        else
            result = 0;
    else
        result = RoundTowardsZero(SInt(R[n]) / SInt(R[m]));
    R[d] = result<31:0>;
```

Exceptions

In ARMv7-R profile, Undefined Instruction, see *Divide instructions* on page A4-172.

In ARMv7-A profile, none.

Overflow

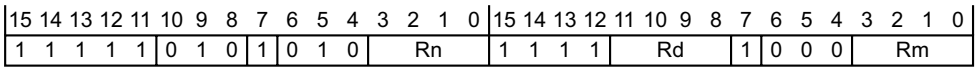
If the signed integer division `0x80000000 / 0xFFFFFFFF` is performed, the pseudocode produces the intermediate integer result $+2^{31}$, that overflows the 32-bit signed integer range. No indication of this overflow case is produced, and the 32-bit result written to `R[d]` must be the bottom 32 bits of the binary representation of $+2^{31}$. So the result of the division is `0x80000000`.

A8.8.166 SEL

Select Bytes selects each byte of its result from either its first operand or its second operand, according to the values of the GE flags.

Encoding T1 ARMv6T2, ARMv7

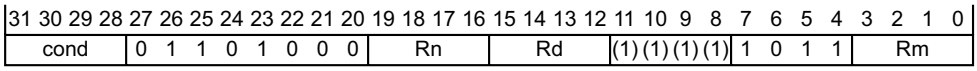
```
SEL<c> <Rd>, <Rn>, <Rm>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);
if d IN {13,15} || n IN {13,15} || m IN {13,15} then UNPREDICTABLE;
```

Encoding A1 ARMv6*, ARMv7

```
SEL<c> <Rd>, <Rn>, <Rm>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE;
```

Assembler syntax

```
SEL{<c>}{<q>}  {<Rd>,} <Rn>, <Rm>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287.

`<Rd>` The destination register.

`<Rn>` The first operand register.

`<Rm>` The second operand register.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    R[d]<7:0>   = if APSR.GE<0> == '1' then R[n]<7:0>   else R[m]<7:0>;
    R[d]<15:8>  = if APSR.GE<1> == '1' then R[n]<15:8>  else R[m]<15:8>;

```

Exceptions

None.

A8.8.175 SMC (previously SMI)

Secure Monitor Call is a system instruction. For details see *SMC (previously SMI)* on page B9-2000.

A8.8.176 SMLABB, SMLABT, SMLATB, SMLATT

Signed Multiply Accumulate (halfwords) performs a signed multiply accumulate operation. The multiply acts on two signed 16-bit quantities, taken from either the bottom or the top half of their respective source registers. The other halves of these source registers are ignored. The 32-bit product is added to a 32-bit accumulate value and the result is written to the destination register.

If overflow occurs during the addition of the accumulate value, the instruction sets the Q flag in the APSR. It is not possible for overflow to occur during the multiplication.

Encoding T1 ARMv6T2, ARMv7

```
SMLA<x><y><c> <Rd>, <Rn>, <Rm>, <Ra>
```

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

```

Assembler syntax

```
SMLA<x><y>{<c>}{<q>}  <Rd>, <Rn>, <Rm>, <Ra>
```

where:

<x> Specifies which half of the source register <Rn> is used as the first multiply operand. If <x> is B, then the bottom half (bits[15:0]) of <Rn> is used. If <x> is T, then the top half (bits[31:16]) of <Rn> is used.

<y> Specifies which half of the source register <Rm> is used as the second multiply operand. If <y> is B, then the bottom half (bits[15:0]) of <Rm> is used. If <y> is T, then the top half (bits[31:16]) of <Rm> is used.

<c>, <q> See *Standard assembler syntax fields* on page A8-287.

<Rd> The destination register.

<Rn> The source register whose bottom or top half (selected by <x>) is the first multiply operand.

<Rm> The source register whose bottom or top half (selected by <y>) is the second multiply operand.

<Ra> The register that contains the accumulate value.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    operand1 = if n_high then R[n]<31:16> else R[n]<15:0>;
    operand2 = if m_high then R[m]<31:16> else R[m]<15:0>;
    result = SInt(operand1) * SInt(operand2) + SInt(R[a]);
    R[d] = result<31:0>;
    if result != SInt(result<31:0>) then  // Signed overflow
        APSR.Q = '1';
```

Exceptions

None.

A8.8.177 SMLAD

Signed Multiply Accumulate Dual performs two signed 16 × 16-bit multiplications. It adds the products to a 32-bit accumulate operand.

Optionally, the instruction can exchange the halfwords of the second operand before performing the arithmetic. This produces top × bottom and bottom × top multiplication.

This instruction sets the Q flag if the accumulate operation overflows. Overflow cannot occur during the multiplications.

    product2 = SInt(R[n]<31:16>) * SInt(operand2<31:16>);
    result = product1 + product2 + SInt(R[a]);
    R[d] = result<31:0>;
    if result != SInt(result<31:0>) then  // Signed overflow
        APSR.Q = '1';
```

Exceptions

None.

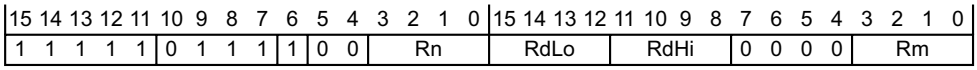
A8.8.178 SMLAL

Signed Multiply Accumulate Long multiplies two signed 32-bit values to produce a 64-bit value, and accumulates this with a 64-bit value.

In ARM instructions, the condition flags can optionally be updated based on the result. Use of this option adversely affects performance on many processor implementations.

Encoding T1 ARMv6T2, ARMv7

```
SMLAL<c> <RdLo>, <RdHi>, <Rn>, <Rm>
```



```
dLo = UInt(RdLo);  dHi = UInt(RdHi);  n = UInt(Rn);  m = UInt(Rm);  setflags = FALSE;

```

Assembler syntax

```
SMLAL{S}{<c>}{<q>}  <RdLo>, <RdHi>, <Rn>, <Rm>
```

where:

S	If S is present, the instruction updates the flags. Otherwise, the flags are not updated. S can be specified only for the ARM instruction set.
<c>, <q>	See *Standard assembler syntax fields* on page A8-287.
<RdLo>	Supplies the lower 32 bits of the accumulate value, and is the destination register for the lower 32 bits of the result.
<RdHi>	Supplies the upper 32 bits of the accumulate value, and is the destination register for the upper 32 bits of the result.
<Rn>	The first operand register.
<Rm>	The second operand register.

The pre-UAL syntax SMLAL<c>S is equivalent to SMLALS<c>.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    result = SInt(R[n]) * SInt(R[m]) + SInt(R[dHi]:R[dLo]);
    R[dHi] = result<63:32>;
    R[dLo] = result<31:0>;
    if setflags then
        APSR.N = result<63>;
        APSR.Z = IsZeroBit(result<63:0>);
        if ArchVersion() == 4 then
            APSR.C = bit UNKNOWN;
            APSR.V = bit UNKNOWN;
        // else APSR.C, APSR.V unchanged
```

Exceptions

None.

A8.8.179 SMLALBB, SMLALBT, SMLALTB, SMLALTT

Signed Multiply Accumulate Long (halfwords) multiplies two signed 16-bit values to produce a 32-bit value, and accumulates this with a 64-bit value. The multiply acts on two signed 16-bit quantities, taken from either the bottom or the top half of their respective source registers. The other halves of these source registers are ignored. The 32-bit product is sign-extended and accumulated with a 64-bit accumulate value.

Overflow is possible during this instruction, but only as a result of the 64-bit addition. This overflow is not detected if it occurs. Instead, the result wraps around modulo 2^{64}.

Encoding T1 ARMv6T2, ARMv7

```

A8.8.181 SMLAWB, SMLAWT

Signed Multiply Accumulate (word by halfword) performs a signed multiply accumulate operation. The multiply acts on a signed 32-bit quantity and a signed 16-bit quantity. The signed 16-bit quantity is taken from either the bottom or the top half of its source register. The other half of the second source register is ignored. The top 32 bits of the 48-bit product are added to a 32-bit accumulate value and the result is written to the destination register. The bottom 16 bits of the 48-bit product are ignored.

If overflow occurs during the addition of the accumulate value, the instruction sets the Q flag in the APSR. No overflow can occur during the multiplication.

<Rd>	The destination register.
<Rn>	The register that contains the first multiply operand.
<Rm>	The register that contains the second multiply operand.
<Ra>	The register that contains the accumulate value.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    result = (SInt(R[a]) << 32) - SInt(R[n]) * SInt(R[m]);
    if round then result = result + 0x80000000;
    R[d] = result<63:32>;
```

Exceptions

None.

A8.8.186 SMMUL

Signed Most Significant Word Multiply multiplies two signed 32-bit values, extracts the most significant 32 bits of the result, and writes those bits to the destination register.

Optionally, the instruction can specify that the result is rounded instead of being truncated. In this case, the constant `0x80000000` is added to the product before the high word is extracted.

Encoding T1 ARMv6T2, ARMv7

```
SMMUL{R}<c> <Rd>, <Rn>, <Rm>
```

<Rd>	The destination register.
<Rn>	The first operand register.
<Rm>	The second operand register.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    result = SInt(R[n]) * SInt(R[m]);
    if round then result = result + 0x80000000;
    R[d] = result<63:32>;
```

Exceptions

None.

A8.8.187 SMUAD

Signed Dual Multiply Add performs two signed 16 × 16-bit multiplications. It adds the products together, and writes the result to the destination register.

Optionally, the instruction can exchange the halfwords of the second operand before performing the arithmetic. This produces top × bottom and bottom × top multiplication.

This instruction sets the Q flag if the addition overflows. The multiplications cannot overflow.

Encoding T1 ARMv6T2, ARMv7

```

A8.8.192 SRS

Store Return State is a system instruction. For details see *SRS (Thumb)* on page B9-2002 and *SRS (ARM)* on page B9-2004.

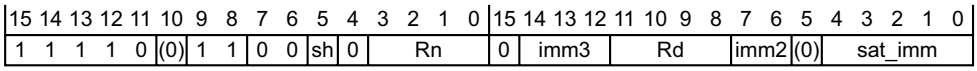
A8.8.193 SSAT

Signed Saturate saturates an optionally-shifted signed value to a selectable signed range.

The Q flag is set if the operation saturates.

Encoding T1 ARMv6T2, ARMv7

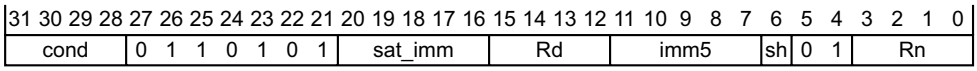
```
SSAT<c> <Rd>, #<imm>, <Rn>{, <shift>}
```



```
if sh == '1' && (imm3:imm2) == '00000' then SEE SSAT16;
d = UInt(Rd);  n = UInt(Rn);  saturate_to = UInt(sat_imm)+1;
(shift_t, shift_n) = DecodeImmShift(sh:'0', imm3:imm2);
if d IN {13,15} || n IN {13,15} then UNPREDICTABLE;
```

Encoding A1 ARMv6*, ARMv7

```
SSAT<c> <Rd>, #<imm>, <Rn>{, <shift>}
```



```
d = UInt(Rd);  n = UInt(Rn);  saturate_to = UInt(sat_imm)+1;
(shift_t, shift_n) = DecodeImmShift(sh:'0', imm5);
if d == 15 || n == 15 then UNPREDICTABLE;
```

Assembler syntax

```
SSAT{<c>}{<q>}  <Rd>, #<imm>, <Rn> {, <shift>}
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287.

`<Rd>` The destination register.

`<imm>` The bit position for saturation, in the range 1 to 32. The `sat_imm` field of the instruction encodes this bit position, by taking the value (`<imm>`-1).

`<Rn>` The register that contains the value to be saturated.

`<shift>` The optional shift, encoded in the `sh` bit and the `immsh` field, where `immsh` is:

- `imm3:imm2` for encoding T1
- `imm5` for encoding A1.

`<shift>` must be one of:

omitted No shift. Encoded as `sh` = 0, `immsh` = `0b00000`.

`LSL #<n>` Left shift by `<n>` bits, with `<n>` in the range 1-31.
Encoded as `sh` = 0, `immsh` = `<n>`.

`ASR #<n>` Arithmetic right shift by `<n>` bits, with `<n>` in the range 1-31.
Encoded as `sh` = 1, `immsh` = `<n>`.

`ASR #32` Arithmetic right shift by 32 bits, permitted only for encoding A1.
Encoded as `sh` = 1, `immsh` = `0b00000`.

Note

An assembler can permit `ASR #0` or `LSL #0` to mean the same thing as omitting the shift, but this is not standard UAL and must not be used for disassembly.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    operand = Shift(R[n], shift_t, shift_n, APSR.C);  // APSR.C ignored
    (result, sat) = SignedSatQ(SInt(operand), saturate_to);
    R[d] = SignExtend(result, 32);
    if sat then
        APSR.Q = '1';
```

Exceptions

None.

A8.8.194 SSAT16

Signed Saturate 16 saturates two signed 16-bit values to a selected signed range.

The Q flag is set if the operation saturates.

Encoding T1 ARMv6T2, ARMv7

```
SSAT16<c> <Rd>, #<imm>, <Rn>
```

```

Exceptions

None.

A8.8.198 STC, STC2

Store Coprocessor stores data from a coprocessor to a sequence of consecutive memory addresses. If no coprocessor can execute the instruction, an Undefined Instruction exception is generated.

This is a generic coprocessor instruction. Some of the fields have no functionality defined by the architecture and are free for use by the coprocessor instruction set designer. These are the `D` bit, the `CRd` field, and in the Unindexed addressing mode only, the `imm8` field. However, coprocessors CP8-CP15 are reserved for use by ARM, and this manual defines the valid `STC` and `STC2` instructions when `coproc` is in the range `p8-p15`. For more information see *Coprocessor support* on page A2-94.

In an implementation that includes the Virtualization Extensions, the permitted `STC` access to a system control register can be trapped to Hyp mode, meaning that an attempt to execute an `STC` instruction in a Non-secure mode other than Hyp mode, that would be permitted in the absence of the Hyp trap controls, generates a Hyp Trap exception. For more information, see *Trapping general CP14 accesses to debug registers* on page B1-1260.

Note

For simplicity, the `STC` pseudocode does not show this possible trap to Hyp mode.

```

Advanced SIMD and Floating-point See *Extension register load/store instructions* on page A7-274

Assembler syntax

`STC{2}{L}{<c>}{<q>}  <coproc>, <CRd>, [<Rn>{, #+/-<imm>}]`	Offset. P = 1, W = 0.
`STC{2}{L}{<c>}{<q>}  <coproc>, <CRd>, [<Rn>, #+/-<imm>]!`	Pre-indexed. P = 1, W = 1.
`STC{2}{L}{<c>}{<q>}  <coproc>, <CRd>, [<Rn>], #+/-<imm>`	Post-indexed. P = 0, W = 1.
`STC{2}{L}{<c>}{<q>}  <coproc>, <CRd>, [<Rn>], <option>`	Unindexed. P = 0, W = 0, U = 1.

where:

`2`	If specified, selects encoding T2/A2. If omitted, selects encoding T1/A1.
`L`	If specified, selects the D == 1 form of the encoding. If omitted, selects the D == 0 form.
`<c>, <q>`	See *Standard assembler syntax fields* on page A8-287. An ARM `STC2` instruction must be unconditional.
`<coproc>`	The name of the coprocessor. The generic coprocessor names are p0-p15.
`<CRd>`	The coprocessor source register.
`<Rn>`	The base register. The SP can be used. In the ARM instruction set, for offset and unindexed addressing only, the PC can be used. However, ARM deprecates use of the PC.
`+/-`	Is + or omitted if the immediate offset is to be added to the base register value (`add == TRUE`), or – if it is to be subtracted (`add == FALSE`). `#0` and `#-0` generate different instructions.
`<imm>`	The immediate offset used for forming the address. Values are multiples of 4 in the range 0-1020. For the offset addressing syntax, `<imm>` can be omitted, meaning an offset of +0.
`<option>`	A coprocessor option. An integer in the range 0-255 enclosed in { }. Encoded in imm8.

The pre-UAL syntax `STC<c>L` is equivalent to `STCL<c>`.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if !Coproc_Accepted(cp, ThisInstr()) then
        GenerateCoprocessorException();
    else
        NullCheckIfThumbEE(n);
        offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
        address = if index then offset_addr else R[n];
        repeat
            MemA[address,4] = Coproc_GetWordToStore(cp, ThisInstr());
            address = address + 4;
        until Coproc_DoneStoring(cp, ThisInstr());
        if wback then R[n] = offset_addr;
```

Exceptions

Undefined Instruction, Data Abort, Hyp Trap.

Uses of these instructions by specific coprocessors might generate other exceptions.

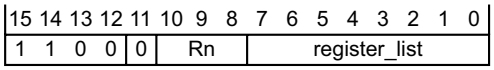
A8.8.199 STM (STMIA, STMEA)

Store Multiple Increment After (Store Multiple Empty Ascending) stores multiple registers to consecutive memory locations using an address from a base register. The consecutive memory locations start at this address, and the address just above the last of those locations can optionally be written back to the base register.

For details of related system instructions see *STM (User registers)* on page B9-2006.

Encoding T1 ARMv4T, ARMv5T*, ARMv6*, ARMv7 (not in ThumbEE)

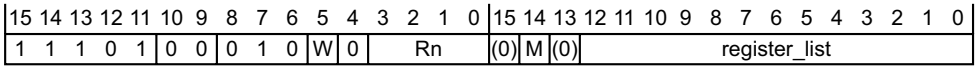
```
STM<c> <Rn>!, <registers>
```



```
if CurrentInstrSet() == InstrSet_ThumbEE then SEE "ThumbEE instructions";
n = UInt(Rn);  registers = '00000000':register_list;  wback = TRUE;
if BitCount(registers) < 1 then UNPREDICTABLE;
```

Encoding T2 ARMv6T2, ARMv7

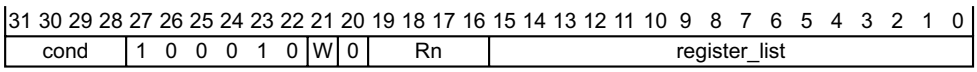
```
STM<c>.W <Rn>{!}, <registers>
```



```
n = UInt(Rn);  registers = '0':M:'0':register_list;  wback = (W == '1');
if n == 15 || BitCount(registers) < 2 then UNPREDICTABLE;
if wback && registers<n> == '1' then UNPREDICTABLE;
```

Encoding A1 ARMv4*, ARMv5T*, ARMv6*, ARMv7

```
STM<c> <Rn>{!}, <registers>
```



```
n = UInt(Rn);  registers = register_list;  wback = (W == '1');
if n == 15 || BitCount(registers) < 1 then UNPREDICTABLE;
```

ThumbEE instructions

See *16-bit ThumbEE instructions* on page A9-1115.

Assembler syntax

```
STM{<c>}{<q>}  <Rn>{!}, <registers>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287.

`<Rn>` The base register. The SP can be used.

`!` Causes the instruction to write a modified value back to `<Rn>`. Encoded as W = 1.

If `!` is omitted, the instruction does not change `<Rn>` in this way. Encoded as W = 0.

`<registers>` Is a list of one or more registers to be stored, separated by commas and surrounded by `{` and `}`. The lowest-numbered register is stored to the lowest memory address, through to the highest-numbered register to the highest memory address. See also *Encoding of lists of ARM core registers* on page A8-295.

Encoding T2 does not support a list containing only one register. If an `STM` instruction with just one register `<Rt>` in the list is assembled to Thumb and encoding T1 is not available, it is assembled to the equivalent `STR{<c>}{<q>} <Rt>, [<Rn>]{, #4}` instruction.

The SP and PC can be in the list in ARM instructions, but not in Thumb instructions. However, ARM deprecates the use of ARM instructions that include the SP or the PC in the list.

ARM deprecates the use of instructions with the base register in the list and ! specified. If the base register is not the lowest-numbered register in the list, such an instruction stores an UNKNOWN value for the base register.

An instruction with the base register in the list and ! specified cannot use encoding T2.

`STMEA` and `STMIA` are pseudo-instructions for `STM`. `STMEA` refers to its use for pushing data onto Empty Ascending stacks.

The pre-UAL syntaxes `STM<c>IA` and `STM<c>EA` are equivalent to `STM<c>`.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  NullCheckIfThumbEE(n);
    address = R[n];
    for i = 0 to 14
        if registers<i> == '1' then
            if i == n && wback && i != LowestSetBit(registers) then
                MemA[address,4] = bits(32) UNKNOWN;  // Only possible for encodings T1 and A1
            else
                MemA[address,4] = R[i];
            address = address + 4;
    if registers<15> == '1' then  // Only possible for encoding A1
        MemA[address,4] = PCStoreValue();
    if wback then R[n] = R[n] + 4*BitCount(registers);
```

Exceptions

Data Abort.

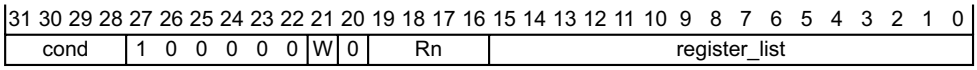
A8.8.200 STMDA (STMED)

Store Multiple Decrement After (Store Multiple Empty Descending) stores multiple registers to consecutive memory locations using an address from a base register. The consecutive memory locations end at this address, and the address just below the lowest of those locations can optionally be written back to the base register.

For details of related system instructions see *STM (User registers)* on page B9-2006.

Encoding A1 ARMv4*, ARMv5T*, ARMv6*, ARMv7

```
STMDA<c> <Rn>{!}, <registers>
```



```
n = UInt(Rn);  registers = register_list;  wback = (W == '1');
if n == 15 || BitCount(registers) < 1 then UNPREDICTABLE;
```

Assembler syntax

```
STMDA{<c>}{<q>}  <Rn>{!}, <registers>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287.

`<Rn>` The base register. The SP can be used.

`!` Causes the instruction to write a modified value back to `<Rn>`. Encoded as W = 1.

If `!` is omitted, the instruction does not change `<Rn>` in this way. Encoded as W = 0.

`<registers>` Is a list of one or more registers to be stored, separated by commas and surrounded by `{` and `}`. The lowest-numbered register is stored to the lowest memory address, through to the highest-numbered register to the highest memory address. See also *Encoding of lists of ARM core registers* on page A8-295.

The SP and PC can be in the list. However, instructions that include the SP or the PC in the list are deprecated.

ARM deprecates the use of instructions with the base register in the list and ! specified. If the base register is not the lowest-numbered register in the list, such an instruction stores an UNKNOWN value for the base register.

`STMED` is s pseudo-instruction for `STMDA`, referring to its use for pushing data onto Empty Descending stacks.

The pre-UAL syntaxes `STM<c>DA` and `STM<c>ED` are equivalent to `STMDA<c>`.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    address = R[n] - 4*BitCount(registers) + 4;
    for i = 0 to 14
        if registers<i> == '1' then
            if i == n && wback && i != LowestSetBit(registers) then
                MemA[address,4] = bits(32) UNKNOWN;
            else
                MemA[address,4] = R[i];
            address = address + 4;
    if registers<15> == '1' then
        MemA[address,4] = PCStoreValue();
    if wback then R[n] = R[n] - 4*BitCount(registers);
```

Exceptions

Data Abort.

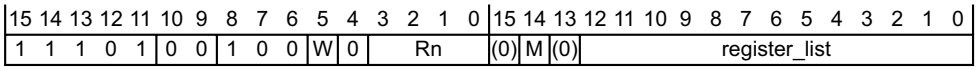
A8.8.201 STMDB (STMFD)

Store Multiple Decrement Before (Store Multiple Full Descending) stores multiple registers to consecutive memory locations using an address from a base register. The consecutive memory locations end just below this address, and the address of the first of those locations can optionally be written back to the base register.

For details of related system instructions see *STM (User registers)* on page B9-2006.

Encoding T1 ARMv6T2, ARMv7

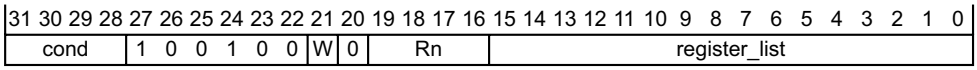
```
STMDB<c> <Rn>{!}, <registers>
```



```
if W == '1' && Rn == '1101' then SEE PUSH;
n = UInt(Rn);  registers = '0':M:'0':register_list;  wback = (W == '1');
if n == 15 || BitCount(registers) < 2 then UNPREDICTABLE;
if wback && registers<n> == '1' then UNPREDICTABLE;
```

Encoding A1 ARMv4*, ARMv5T*, ARMv6*, ARMv7

```
STMDB<c> <Rn>{!}, <registers>
```



```
if W == '1' && Rn == '1101' && BitCount(register_list) >= 2 then SEE PUSH;
n = UInt(Rn);  registers = register_list;  wback = (W == '1');
if n == 15 || BitCount(registers) < 1 then UNPREDICTABLE;
```

Assembler syntax

```
STMDB{<c>}{<q>}  <Rn>{!}, <registers>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287.

`<Rn>` The base register. The SP can be used. If the SP is used, and ! is specified:

- for encoding T1, it is treated as described in *PUSH* on page A8-538
- for encoding A1, if there is more than one register in the `<registers>` list, it is treated as described in *PUSH* on page A8-538.

`!` Causes the instruction to write a modified value back to `<Rn>`. Encoded as W = 1.

If ! is omitted, the instruction does not change `<Rn>` in this way. Encoded as W = 0.

`<registers>` Is a list of one or more registers to be stored, separated by commas and surrounded by { and }. The lowest-numbered register is stored to the lowest memory address, through to the highest-numbered register to the highest memory address. See also *Encoding of lists of ARM core registers* on page A8-295.

Encoding T1 does not support a list containing only one register. If an `STMDB` instruction with just one register `<Rt>` in the list is assembled to Thumb, it is assembled to the equivalent `STR{<c>}{<q>} <Rt>, [<Rn>, #-4]{!}` instruction.

The SP and PC can be in the list in ARM instructions, but not in Thumb instructions. However, ARM deprecates the use of ARM instructions that include the SP or the PC in the list.

Instructions with the base register in the list and ! specified are only available in the ARM instruction set, and ARM deprecates the use of such instructions. If the base register is not the lowest-numbered register in the list, such an instruction stores an UNKNOWN value for the base register.

`STMFD` is a pseudo-instruction for `STMDB`, referring to its use for pushing data onto Full Descending stacks.

The pre-UAL syntaxes `STM<c>DB` and `STM<c>FD` are equivalent to `STMDB<c>`.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  NullCheckIfThumbEE(n);
    address = R[n] - 4*BitCount(registers);
    for i = 0 to 14
        if registers<i> == '1' then
            if i == n && wback && i != LowestSetBit(registers) then
                MemA[address,4] = bits(32) UNKNOWN;  // Only possible for encoding A1
            else
                MemA[address,4] = R[i];
            address = address + 4;
    if registers<15> == '1' then  // Only possible for encoding A1
        MemA[address,4] = PCStoreValue();
    if wback then R[n] = R[n] - 4*BitCount(registers);
```

Exceptions

Data Abort.

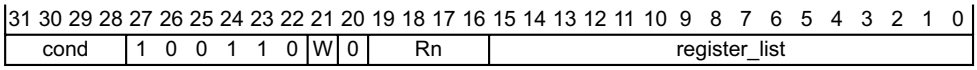
A8.8.202 STMIB (STMFA)

Store Multiple Increment Before (Store Multiple Full Ascending) stores multiple registers to consecutive memory locations using an address from a base register. The consecutive memory locations start just above this address, and the address of the last of those locations can optionally be written back to the base register.

For details of related system instructions see *STM (User registers)* on page B9-2006.

Encoding A1 ARMv4*, ARMv5T*, ARMv6*, ARMv7

```
STMIB<c> <Rn>{!}, <registers>
```



```
n = UInt(Rn);  registers = register_list;  wback = (W == '1');
if n == 15 || BitCount(registers) < 1 then UNPREDICTABLE;
```

Assembler syntax

```
STMIB{<c>}{<q>}  <Rn>{!}, <registers>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287.

`<Rn>` The base register. The SP can be used.

`!` Causes the instruction to write a modified value back to `<Rn>`. Encoded as W = 1.

If `!` is omitted, the instruction does not change `<Rn>` in this way. Encoded as W = 0.

`<registers>` Is a list of one or more registers to be stored, separated by commas and surrounded by `{` and `}`. The lowest-numbered register is stored to the lowest memory address, through to the highest-numbered register to the highest memory address. See also *Encoding of lists of ARM core registers* on page A8-295.

The SP and PC can be in the list. However, instructions that include the SP or the PC in the list are deprecated.

ARM deprecates the use of instructions with the base register in the list and ! specified. If the base register is not the lowest-numbered register in the list, such an instruction stores an UNKNOWN value for the base register.

`STMFA` is a pseudo-instruction for `STMIB`, referring to its use for pushing data onto Full Ascending stacks.

The pre-UAL syntax `STM<c>IB` and `STM<c>FA` are equivalent to `STMIB<c>`.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    address = R[n] + 4;
    for i = 0 to 14
        if registers<i> == '1' then
            if i == n && wback && i != LowestSetBit(registers) then
                MemA[address,4] = bits(32) UNKNOWN;
            else
                MemA[address,4] = R[i];
            address = address + 4;
    if registers<15> == '1' then
        MemA[address,4] = PCStoreValue();
    if wback then R[n] = R[n] + 4*BitCount(registers);
```

Exceptions

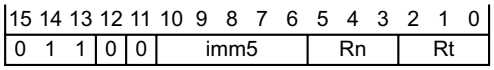
Data Abort.

A8.8.203 STR (immediate, Thumb)

Store Register (immediate) calculates an address from a base register value and an immediate offset, and stores a word from a register to memory. It can use offset, post-indexed, or pre-indexed addressing. For information about memory accesses see *Memory accesses* on page A8-294.

Encoding T1 ARMv4T, ARMv5T*, ARMv6*, ARMv7

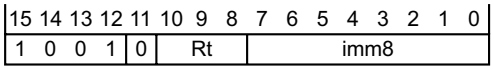
```
STR<c> <Rt>, [<Rn>{, #<imm>}]
```



```
t = UInt(Rt);  n = UInt(Rn);  imm32 = ZeroExtend(imm5:'00', 32);
index = TRUE;  add = TRUE;  wback = FALSE;
```

Encoding T2 ARMv4T, ARMv5T*, ARMv6*, ARMv7

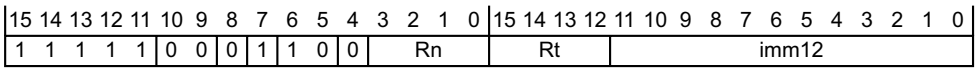
```
STR<c> <Rt>, [SP, #<imm>]
```



```
t = UInt(Rt);  n = 13;  imm32 = ZeroExtend(imm8:'00', 32);
index = TRUE;  add = TRUE;  wback = FALSE;
```

Encoding T3 ARMv6T2, ARMv7

```
STR<c>.W <Rt>, [<Rn>, #<imm12>]
```



```

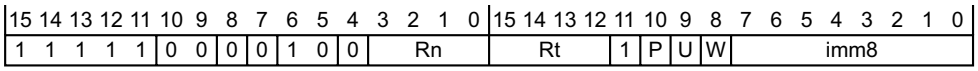
t = UInt(Rt);  n = UInt(Rn);  imm32 = ZeroExtend(imm12, 32);
index = TRUE;  add = TRUE;  wback = FALSE;
if t == 15 then UNPREDICTABLE;
```

Encoding T4 ARMv6T2, ARMv7

```
STR<c> <Rt>, [<Rn>, #-<imm8>]
STR<c> <Rt>, [<Rn>], #+/-<imm8>
STR<c> <Rt>, [<Rn>, #+/-<imm8>]!
```



```
if P == '1' && U == '1' && W == '0' then SEE STRT;
if Rn == '1101' && P == '1' && U == '0' && W == '1' && imm8 == '00000100' then SEE PUSH;
if Rn == '1111' || (P == '0' && W == '0') then UNDEFINED;
t = UInt(Rt);  n = UInt(Rn);  imm32 = ZeroExtend(imm8, 32);
index = (P == '1');  add = (U == '1');  wback = (W == '1');
if t == 15 || (wback && n == t) then UNPREDICTABLE;
```

Assembler syntax

`STR{<c>}{<q>} <Rt>, [<Rn> {, #+/-<imm>}]`	Offset: `index==TRUE`, `wback==FALSE`
`STR{<c>}{<q>} <Rt>, [<Rn>, #+/-<imm>]!`	Pre-indexed: `index==TRUE`, `wback==TRUE`
`STR{<c>}{<q>} <Rt>, [<Rn>], #+/-<imm>`	Post-indexed: `index==FALSE`, `wback==TRUE`

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287.

`<Rt>` The source register. The SP can be used.

`<Rn>` The base register. The SP can be used.

`+/-` Is + or omitted if the immediate offset is to be added to the base register value (`add == TRUE`), or – if it is to be subtracted (`add == FALSE`). `#0` and `#-0` generate different instructions.

`<imm>` The immediate offset used for forming the address. Values are:

Encoding T1 multiples of 4 in the range 0-124

Encoding T2 multiples of 4 in the range 0-1020

Encoding T3 any value in the range 0-4095

Encoding T4 any value in the range 0-255.

For the offset addressing syntax, `<imm>` can be omitted, meaning an offset of 0.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  NullCheckIfThumbEE(n);
    offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
    address = if index then offset_addr else R[n];
    if UnalignedSupport() || address<1:0> == '00' then
        MemU[address,4] = R[t];
    else // Can only occur before ARMv7
        MemU[address,4] = bits(32) UNKNOWN;
    if wback then R[n] = offset_addr;
```

Exceptions

Data Abort.

ThumbEE instruction

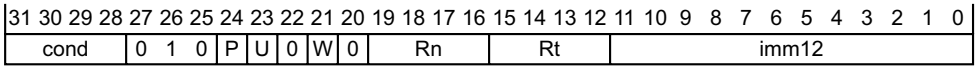
ThumbEE has an additional `STR` (immediate) encoding. For details see *STR (immediate)* on page A9-1130.

A8.8.204 STR (immediate, ARM)

Store Register (immediate) calculates an address from a base register value and an immediate offset, and stores a word from a register to memory. It can use offset, post-indexed, or pre-indexed addressing. For information about memory accesses see *Memory accesses* on page A8-294.

Encoding A1 ARMv4*, ARMv5T*, ARMv6*, ARMv7

```
STR<c> <Rt>, [<Rn>{, #+/-<imm12>}]
STR<c> <Rt>, [<Rn>], #+/-<imm12>
STR<c> <Rt>, [<Rn>, #+/-<imm12>]!
```



```
if P == '0' && W == '1' then SEE STRT;
if Rn == '1101' && P == '1' && U == '0' && W == '1' && imm12 == '000000000100' then SEE PUSH;
t = UInt(Rt);  n = UInt(Rn);  imm32 = ZeroExtend(imm12, 32);
index = (P == '1');  add = (U == '1');  wback = (P == '0') || (W == '1');
if wback && (n == 15 || n == t) then UNPREDICTABLE;
```

Assembler syntax

`STR{<c>}{<q>} <Rt>, [<Rn> {, #+/-<imm>}]`	Offset: `index==TRUE, wback==FALSE`
`STR{<c>}{<q>} <Rt>, [<Rn>, #+/-<imm>]!`	Pre-indexed: `index==TRUE, wback==TRUE`
`STR{<c>}{<q>} <Rt>, [<Rn>], #+/-<imm>`	Post-indexed: `index==FALSE, wback==TRUE`

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287.

`<Rt>` The source register. The SP or the PC can be used. However, ARM deprecates use of the PC.

`<Rn>` The base register. The SP can be used. For offset addressing only, the PC can be used. However, ARM deprecates use of the PC.

`+/-` Is + or omitted if the immediate offset is to be added to the base register value (`add == TRUE`), or – if it is to be subtracted (`add == FALSE`). `#0` and `#-0` generate different instructions.

`<imm>` The immediate offset used for forming the address. Any value in the range 0-4095 is permitted. For the offset addressing syntax, `<imm>` can be omitted, meaning an offset of 0.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
    address = if index then offset_addr else R[n];
    MemU[address,4] = if t == 15 then PCStoreValue() else R[t];
    if wback then R[n] = offset_addr;
```

Exceptions

Data Abort.

A8.8.205 STR (register)

Store Register (register) calculates an address from a base register value and an offset register value, stores a word from a register to memory. The offset register value can optionally be shifted. For information about memory accesses see *Memory accesses* on page A8-294.

Encoding T1 ARMv4T, ARMv5T*, ARMv6*, ARMv7

```
STR<c> <Rt>, [<Rn>, <Rm>]
```

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	0	1	0	0	0	Rm			Rn			Rt		

```
if CurrentInstrSet() == InstrSet_ThumbEE then SEE "Modified operation in ThumbEE";
t = UInt(Rt);  n = UInt(Rn);  m = UInt(Rm);
index = TRUE;  add = TRUE;  wback = FALSE;
(shift_t, shift_n) = (SRType_LSL, 0);
```

Encoding T2 ARMv6T2, ARMv7

```
STR<c>.W <Rt>, [<Rn>, <Rm>{, LSL #<imm2>}]
```

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

```
if Rn == '1111' then UNDEFINED;
t = UInt(Rt);  n = UInt(Rn);  m = UInt(Rm);
index = TRUE;  add = TRUE;  wback = FALSE;
(shift_t, shift_n) = (SRType_LSL, UInt(imm2));
if t == 15 || m IN {13,15} then UNPREDICTABLE;
```

Encoding A1 ARMv4*, ARMv5T*, ARMv6*, ARMv7

```
STR<c> <Rt>, [<Rn>,+/-<Rm>{, <shift>}]{!}
STR<c> <Rt>, [<Rn>],+/-<Rm>{, <shift>}
```

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond				0	1	1	P	U	0	W	0	Rn				Rt				imm5					type		0	Rm			

```
if P == '0' && W == '1' then SEE STRT;
t = UInt(Rt);  n = UInt(Rn);  m = UInt(Rm);
index = (P == '1');  add = (U == '1');  wback = (P == '0') || (W == '1');
(shift_t, shift_n) = DecodeImmShift(type, imm5);
if m == 15 then UNPREDICTABLE;
if wback && (n == 15 || n == t) then UNPREDICTABLE;
if ArchVersion() < 6 && wback && m == n then UNPREDICTABLE;
```

Modified operation in ThumbEE

See *STR (register)* on page A9-1121

Assembler syntax

`STR{<c>}{<q>} <Rt>, [<Rn>, <Rm>{, <shift>}]`	Offset: `index==TRUE, wback==FALSE`
`STR{<c>}{<q>} <Rt>, [<Rn>, <Rm>{, <shift>}]!`	Pre-indexed: `index==TRUE, wback==TRUE`
`STR{<c>}{<q>} <Rt>, [<Rn>], <Rm>{, <shift>}`	Post-indexed: `index==FALSE, wback==TRUE`

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287.

`<Rt>` The source register. The SP can be used. In the ARM instruction set, the PC can be used. However, ARM deprecates use of the PC.

`<Rn>` The base register. The SP can be used. In the ARM instruction set, for offset addressing only, the PC can be used. However, ARM deprecates use of the PC.

`+/-` Is + or omitted if the optionally shifted value of `<Rm>` is to be added to the base register value (`add == TRUE`), or – if it is to be subtracted (permitted in ARM instructions only, `add == FALSE`).

`<Rm>` Contains the offset that is optionally shifted and added to the value of `<Rn>` to form the address.

`<shift>` The shift to apply to the value read from `<Rm>`. If present, encoding T1 is not permitted. If absent, no shift is applied and all encodings are permitted. For encoding T2, `<shift>` can only be omitted, encoded as imm2 = `0b00`, or `LSL #<imm>` with `<imm>` = 1, 2, or 3, and `<imm>` encoded in imm2. For encoding A1, see *Shifts applied to a register* on page A8-291.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  NullCheckIfThumbEE(n);
    offset = Shift(R[m], shift_t, shift_n, APSR.C);
    offset_addr = if add then (R[n] + offset) else (R[n] - offset);
    address = if index then offset_addr else R[n];
    if t == 15 then  // Only possible for encoding A1
        data = PCStoreValue();
    else
        data = R[t];
    if UnalignedSupport() || address<1:0> == '00' || CurrentInstrSet() == InstrSet_ARM then
        MemU[address,4] = data;
    else // Can only occur before ARMv7
        MemU[address,4] = bits(32) UNKNOWN;
    if wback then R[n] = offset_addr;
```

Exceptions

Data Abort.

A8.8.206 STRB (immediate, Thumb)

Store Register Byte (immediate) calculates an address from a base register value and an immediate offset, and stores a byte from a register to memory. It can use offset, post-indexed, or pre-indexed addressing. For information about memory accesses see *Memory accesses* on page A8-294.

Encoding T1 ARMv4T, ARMv5T*, ARMv6*, ARMv7

    address = if index then offset_addr else R[n];
    MemU[address,1] = R[t]<7:0>;
    if wback then R[n] = offset_addr;
```

Exceptions

Data Abort.

A8.8.209 STRBT

Store Register Byte Unprivileged stores a byte from a register to memory. For information about memory accesses see *Memory accesses* on page A8-294.

The memory access is restricted as if the processor were running in User mode. This makes no difference if the processor is actually running in User mode.

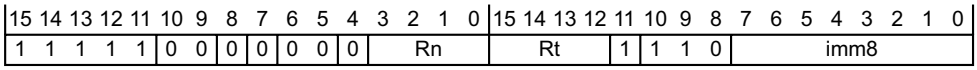
STRBT is UNPREDICTABLE in Hyp mode.

The Thumb instruction uses an offset addressing mode, that calculates the address used for the memory access from a base register value and an immediate offset, and leaves the base register unchanged.

The ARM instruction uses a post-indexed addressing mode, that uses a base register value as the address for the memory access, and calculates a new address from a base register value and an offset and writes it back to the base register. The offset can be an immediate value or an optionally-shifted register value.

Encoding T1 ARMv6T2, ARMv7

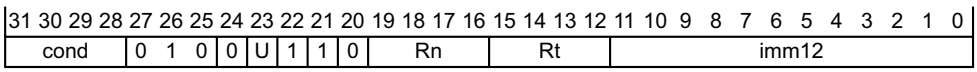
```
STRBT<c> <Rt>, [<Rn>, #<imm8>]
```



```
if Rn == '1111' then UNDEFINED;
t = UInt(Rt);  n = UInt(Rn);  postindex = FALSE;  add = TRUE;
register_form = FALSE;  imm32 = ZeroExtend(imm8, 32);
if t IN {13,15} then UNPREDICTABLE;
```

Encoding A1 ARMv4*, ARMv5T*, ARMv6*, ARMv7

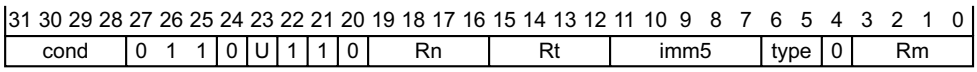
```
STRBT<c> <Rt>, [<Rn>], #+/-<imm12>
```



```
t = UInt(Rt);  n = UInt(Rn);  postindex = TRUE;  add = (U == '1');
register_form = FALSE;  imm32 = ZeroExtend(imm12, 32);
if t == 15 || n == 15 || n == t then UNPREDICTABLE;
```

Encoding A2 ARMv4*, ARMv5T*, ARMv6*, ARMv7

```
STRBT<c> <Rt>, [<Rn>],+/-<Rm>{, <shift>}
```



```
t = UInt(Rt);  n = UInt(Rn);  m = UInt(Rm);  postindex = TRUE;  add = (U == '1');
register_form = TRUE;  (shift_t, shift_n) = DecodeImmShift(type, imm5);
if t == 15 || n == 15 || n == t || m == 15 then UNPREDICTABLE;
if ArchVersion() < 6 && m == n then UNPREDICTABLE;
```

Assembler syntax

`STRBT{<c>}{<q>}  <Rt>, [<Rn> {, #<imm>}]`	Offset: Thumb only
`STRBT{<c>}{<q>}  <Rt>, [<Rn>] {, #<imm>}`	Post-indexed: ARM only
`STRBT{<c>}{<q>}  <Rt>, [<Rn>], +/-<Rm> {, <shift>}`	Post-indexed: ARM only

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287.

`<Rt>` The source register.

`<Rn>` The base register. The SP can be used.

`+/-` Is + or omitted if `<imm>` or the optionally shifted value of `<Rm>` is to be added to the base register value (`add == TRUE`), or – if it is to be subtracted (permitted in ARM instructions only, `add == FALSE`).

`<imm>` The immediate offset applied to the value of `<Rn>`. Values are 0-255 for encoding T1, and 0-4095 for encoding A1. `<imm>` can be omitted, meaning an offset of 0.

`<Rm>` Contains the offset that is optionally shifted and added to the value of `<Rn>` to form the address.

`<shift>` The shift to apply to the value read from `<Rm>`. If omitted, no shift is applied. *Shifts applied to a register* on page A8-291 describes the shifts and how they are encoded.

The pre-UAL syntax `STR<c>BT` is equivalent to `STRBT<c>`.

Operation

```
if ConditionPassed() then
    if CurrentModeIsHyp() then UNPREDICTABLE;               // Hyp mode
    EncodingSpecificOperations();  NullCheckIfThumbEE(n);
    offset = if register_form then Shift(R[m], shift_t, shift_n, APSR.C) else imm32;
    offset_addr = if add then (R[n] + offset) else (R[n] - offset);
    address = if postindex then R[n] else offset_addr;
    MemU_unpriv[address,1] = R[t]<7:0>;
    if postindex then R[n] = offset_addr;
```

Exceptions

Data Abort.

A8.8.210 STRD (immediate)

Store Register Dual (immediate) calculates an address from a base register value and an immediate offset, and stores two words from two registers to memory. It can use offset, post-indexed, or pre-indexed addressing. For information about memory accesses see *Memory accesses* on page A8-294.

Encoding T1 ARMv6T2, ARMv7

```
STRD<c> <Rt>, <Rt2>, [<Rn>{, #+/-<imm>}]
STRD<c> <Rt>, <Rt2>, [<Rn>], #+/-<imm>

Related encodings See *Load/store dual, load/store exclusive, table branch* on page A6-238.

Assembler syntax

`STRD{<c>}{<q>}  <Rt>, <Rt2>, [<Rn> {, #+/-<imm>}]`	Offset: `index==TRUE`, `wback==FALSE`
`STRD{<c>}{<q>}  <Rt>, <Rt2>, [<Rn>, #+/-<imm>]!`	Pre-indexed: `index==TRUE`, `wback==TRUE`
`STRD{<c>}{<q>}  <Rt>, <Rt2>, [<Rn>], #+/-<imm>`	Post-indexed: `index==FALSE`, `wback==TRUE`

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287.

`<Rt>` The first source register. For an ARM instruction, `<Rt>` must be even-numbered and not R14.

`<Rt2>` The second source register. For an ARM instruction, `<Rt2>` must be `<R(t+1)>`.

`<Rn>` The base register. The SP can be used. In the ARM instruction set, for offset addressing only, the PC can be used. However, ARM deprecates use of the PC.

`+/-` Is + or omitted if the immediate offset is to be added to the base register value (`add == TRUE`), or – if it is to be subtracted (`add == FALSE`). `#0` and `#-0` generate different instructions.

`<imm>` The immediate offset used for forming the address. Values are multiples of 4 in the range 0-1020 for encoding T1, and any value in the range 0-255 for encoding A1. For the offset addressing syntax, `<imm>` can be omitted, meaning an offset of 0.

The pre-UAL syntax `STR<c>D` is equivalent to `STRD<c>`.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  NullCheckIfThumbEE(n);
    offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
    address = if index then offset_addr else R[n];
    if HaveLPAE() && address<2:0> == '000' then
        bits(64) data;
        if BigEndian() then
            data<63:32> = R[t];
            data<31:0> = R[t2];
        else
            data<31:0> = R[t];
            data<63:32> = R[t2];
        MemA[Address,8] = data;
    else
        MemA[address,4] = R[t];
        MemA[address+4,4] = R[t2];
    if wback then R[n] = offset_addr;
```

Exceptions

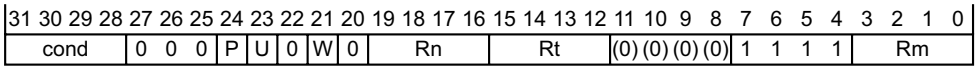
Data Abort.

A8.8.211 STRD (register)

Store Register Dual (register) calculates an address from a base register value and a register offset, and stores two words from two registers to memory. It can use offset, post-indexed, or pre-indexed addressing. For information about memory accesses see *Memory accesses* on page A8-294.

Encoding A1 ARMv5TE*, ARMv6*, ARMv7

```
STRD<c> <Rt>, <Rt2>, [<Rn>,+/-<Rm>]{!}
STRD<c> <Rt>, <Rt2>, [<Rn>],+/-<Rm>
```



```
if Rt<0> == '1' then UNPREDICTABLE;
t = UInt(Rt);  t2 = t+1;  n = UInt(Rn);  m = UInt(Rm);
index = (P == '1');  add = (U == '1');  wback = (P == '0') || (W == '1');
if P == '0' && W == '1' then UNPREDICTABLE;
if t2 == 15 || m == 15 then UNPREDICTABLE;
if wback && (n == 15 || n == t || n == t2) then UNPREDICTABLE;
if ArchVersion() < 6 && wback && m == n then UNPREDICTABLE;
```

Assembler syntax

`STRD{<c>}{<q>}  <Rt>, <Rt2>, [<Rn>, +/-<Rm>]`	Offset: `index==TRUE, wback==FALSE`
`STRD{<c>}{<q>}  <Rt>, <Rt2>, [<Rn>, +/-<Rm>]!`	Pre-indexed: `index==TRUE, wback==TRUE`
`STRD{<c>}{<q>}  <Rt>, <Rt2>, [<Rn>], +/-<Rm>`	Post-indexed: `index==FALSE, wback==TRUE`

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287.

`<Rt>` The first source register. This register must be even-numbered and not R14.

`<Rt2>` The second source register. This register must be `<R(t+1)>`.

`<Rn>` The base register. The SP can be used. For offset addressing only, the PC can be used. However, ARM deprecates use of the PC.

`+/-` Is + or omitted if the immediate offset is to be added to the base register value (`add == TRUE`), or – if it is to be subtracted (`add == FALSE`).

`<Rm>` Contains the offset that is added to the value of `<Rn>` to form the address.

The pre-UAL syntax `STR<c>D` is equivalent to `STRD<c>`.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    offset_addr = if add then (R[n] + R[m]) else (R[n] - R[m]);
    address = if index then offset_addr else R[n];
    if HaveLPAE() && address<2:0> == '000' then
        bits(64) data;
        if BigEndian() then
            data<63:32> = R[t];
            data<31:0> = R[t2];
        else
            data<31:0> = R[t];
            data<63:32> = R[t2];
        MemA[Address,8] = data;
    else
        MemA[address,4] = R[t];
        MemA[address+4,4] = R[t2];
    if wback then R[n] = offset_addr;
```

Exceptions

Data Abort.

A8.8.212 STREX

Store Register Exclusive calculates an address from a base register value and an immediate offset, and stores a word from a register to memory if the executing processor has exclusive access to the memory addressed.

For more information about support for shared memory see *Synchronization and semaphores* on page A3-114. For information about memory accesses see *Memory accesses* on page A8-294.

Encoding T1 ARMv6T2, ARMv7

if d == 15 || t == 15 || n == 15 then UNPREDICTABLE;
if d == n || d == t then UNPREDICTABLE;
```

Assembler syntax

```
STREX{<c>}{<q>}  <Rd>, <Rt>, [<Rn> {, #<imm>}]
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287.

`<Rd>` The destination register for the returned status value. The value returned is:

- `0` if the operation updates memory
- `1` if the operation fails to update memory.

`<Rt>` The source register.

`<Rn>` The base register. The SP can be used.

`<imm>` The immediate offset added to the value of `<Rn>` to form the address. Values are multiples of 4 in the range 0-1020 for encoding T1, and 0 for encoding A1. `<imm>` can be omitted, meaning an offset of 0.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  NullCheckIfThumbEE(n);
    address = R[n] + imm32;
    if ExclusiveMonitorsPass(address,4) then
        MemA[address,4] = R[t];
        R[d] = 0;
    else
        R[d] = 1;
```

Exceptions

Data Abort.

Aborts and alignment

If a synchronous Data Abort exception is generated by the execution of this instruction:

- memory is not updated
- `<Rd>` is not updated.

If SCTLR.A and SCTLR.U are both 0, a non word-aligned memory address causes UNPREDICTABLE behavior. Otherwise, a non word-aligned memory address causes an Alignment fault Data Abort exception to be generated, subject to the following rules:

- If `ExclusiveMonitorsPass()` returns `TRUE`, the exception is generated.
- Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.

If `ExclusiveMonitorsPass()` returns `FALSE` and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

A8.8.213 STREXB

Store Register Exclusive Byte derives an address from a base register value, and stores a byte from a register to memory if the executing processor has exclusive access to the memory addressed.

For more information about support for shared memory see *Synchronization and semaphores* on page A3-114. For information about memory accesses see *Memory accesses* on page A8-294.

Encoding T1 ARMv7

```

if d == 15 || t == 15 || n == 15 then UNPREDICTABLE;
if d == n || d == t then UNPREDICTABLE;
```

Assembler syntax

```
STREXB{<c>}{<q>}  <Rd>, <Rt>, [<Rn>]
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287.

`<Rd>` The destination register for the returned status value. The value returned is:

- `0` if the operation updates memory
- `1` if the operation fails to update memory.

`<Rt>` The source register.

`<Rn>` The base register. The SP can be used.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  NullCheckIfThumbEE(n);
    address = R[n];
    if ExclusiveMonitorsPass(address,1) then
        MemA[address,1] = R[t]<7:0>;
        R[d] = 0;
    else
        R[d] = 1;
```

Exceptions

Data Abort.

Aborts

If a synchronous Data Abort exception is generated by the execution of this instruction:

- memory is not updated
- `<Rd>` is not updated.

If `ExclusiveMonitorsPass()` returns `FALSE` and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

A8.8.214 STREXD

Store Register Exclusive Doubleword derives an address from a base register value, and stores a 64-bit doubleword from two registers to memory if the executing processor has exclusive access to the memory addressed.

For more information about support for shared memory see *Synchronization and semaphores* on page A3-114. For information about memory accesses see *Memory accesses* on page A8-294.

Encoding T1 ARMv7

Assembler syntax

```
STREXH{<c>}{<q>}  <Rd>, <Rt>, [<Rn>]
```

where:

<c>, <q> See *Standard assembler syntax fields* on page A8-287.

<Rd> The destination register for the returned status value. The value returned is:

- 0 if the operation updates memory
- 1 if the operation fails to update memory.

<Rt> The source register.

<Rn> The base register. The SP can be used.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  NullCheckIfThumbEE(n);
    address = R[n];
    if ExclusiveMonitorsPass(address,2) then
        MemA[address,2] = R[t]<15:0>;
        R[d] = 0;
    else
        R[d] = 1;
```

Exceptions

Data Abort.

Aborts and alignment

If a synchronous Data Abort exception is generated by the execution of this instruction:

- memory is not updated
- <Rd> is not updated.

If SCTLR.A and SCTLR.U are both 0, a non halfword-aligned memory address causes UNPREDICTABLE behavior. Otherwise, a non halfword-aligned memory address causes an Alignment fault Data Abort exception to be generated, subject to the following rules:

- If ExclusiveMonitorsPass() returns TRUE, the exception is generated.
- Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.

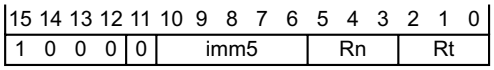
If ExclusiveMonitorsPass() returns FALSE and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

A8.8.216 STRH (immediate, Thumb)

Store Register Halfword (immediate) calculates an address from a base register value and an immediate offset, and stores a halfword from a register to memory. It can use offset, post-indexed, or pre-indexed addressing. For information about memory accesses see *Memory accesses* on page A8-294.

Encoding T1 ARMv4T, ARMv5T*, ARMv6*, ARMv7

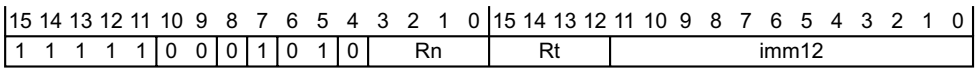
```
STRH<c> <Rt>, [<Rn>{, #<imm>}]
```



```
t = UInt(Rt);  n = UInt(Rn);  imm32 = ZeroExtend(imm5:'0', 32);
index = TRUE;  add = TRUE;  wback = FALSE;
```

Encoding T2 ARMv6T2, ARMv7

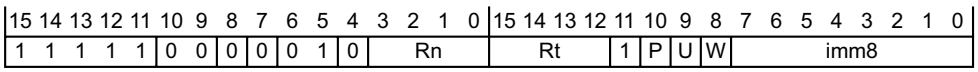
```
STRH<c>.W <Rt>, [<Rn>{, #<imm12>}]
```



```
if Rn == '1111' then UNDEFINED;
t = UInt(Rt);  n = UInt(Rn);  imm32 = ZeroExtend(imm12, 32);
index = TRUE;  add = TRUE;  wback = FALSE;
if t IN {13,15} then UNPREDICTABLE;
```

Encoding T3 ARMv6T2, ARMv7

```
STRH<c> <Rt>, [<Rn>, #-<imm8>]
STRH<c> <Rt>, [<Rn>], #+/-<imm8>
STRH<c> <Rt>, [<Rn>, #+/-<imm8>]!
```



```

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287.

`<Rt>` The source register.

`<Rn>` The base register. The SP can be used. For offset addressing only, the PC can be used. However, ARM deprecates use of the PC.

`+/-` Is + or omitted if the immediate offset is to be added to the base register value (`add == TRUE`), or – if it is to be subtracted (`add == FALSE`). `#0` and `#-0` generate different instructions.

`<imm>` The immediate offset used for forming the address. Values are 0-255. For the offset addressing syntax, `<imm>` can be omitted, meaning an offset of 0.

The pre-UAL syntax `STR<c>H` is equivalent to `STRH<c>`.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
    address = if index then offset_addr else R[n];
    if UnalignedSupport() || address<0> == '0' then
        MemU[address,2] = R[t]<15:0>;
    else // Can only occur before ARMv7
        MemU[address,2] = bits(16) UNKNOWN;
    if wback then R[n] = offset_addr;
```

Exceptions

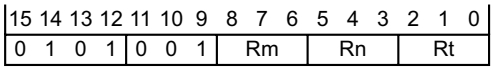
Data Abort.

A8.8.218 STRH (register)

Store Register Halfword (register) calculates an address from a base register value and an offset register value, and stores a halfword from a register to memory. The offset register value can be shifted left by 0, 1, 2, or 3 bits. For information about memory accesses see *Memory accesses* on page A8-294.

Encoding T1 ARMv4T, ARMv5T*, ARMv6*, ARMv7

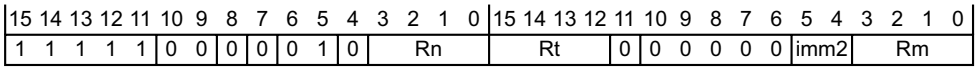
```
STRH<c> <Rt>, [<Rn>, <Rm>]
```



```
if CurrentInstrSet() == InstrSet_ThumbEE then SEE "Modified operation in ThumbEE";
t = UInt(Rt);  n = UInt(Rn);  m = UInt(Rm);
index = TRUE;  add = TRUE;  wback = FALSE;
(shift_t, shift_n) = (SRType_LSL, 0);
```

Encoding T2 ARMv6T2, ARMv7

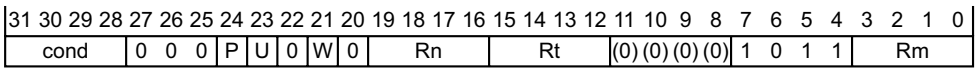
```
STRH<c>.W <Rt>, [<Rn>, <Rm>{, LSL #<imm2>}]
```



```
if Rn == '1111' then UNDEFINED;
t = UInt(Rt);  n = UInt(Rn);  m = UInt(Rm);
index = TRUE;  add = TRUE;  wback = FALSE;
(shift_t, shift_n) = (SRType_LSL, UInt(imm2));
if t IN {13,15} || m IN {13,15} then UNPREDICTABLE;
```

Encoding A1 ARMv4*, ARMv5T*, ARMv6*, ARMv7

```
STRH<c> <Rt>, [<Rn>,+/-<Rm>]{!}
STRH<c> <Rt>, [<Rn>],+/-<Rm>
```



```
if P == '0' && W == '1' then SEE STRHT;
t = UInt(Rt);  n = UInt(Rn);  m = UInt(Rm);
index = (P == '1');  add = (U == '1');  wback = (P == '0') || (W == '1');
(shift_t, shift_n) = (SRType_LSL, 0);
if t == 15 || m == 15 then UNPREDICTABLE;
if wback && (n == 15 || n == t) then UNPREDICTABLE;
if ArchVersion() < 6 && wback && m == n then UNPREDICTABLE;
```

Modified operation in ThumbEE See *STRH (register)* on page A9-1122

Assembler syntax

`STRH{<c>}{<q>}  <Rt>, [<Rn>, +/-<Rm>{, LSL #<imm>}]`	Offset: `index==TRUE`, `wback==FALSE`
`STRH{<c>}{<q>}  <Rt>, [<Rn>, +/-<Rm>]!`	Pre-indexed: `index==TRUE`, `wback==TRUE`
`STRH{<c>}{<q>}  <Rt>, [<Rn>], +/-<Rm>`	Post-indexed: `index==FALSE`, `wback==TRUE`

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287.

`<Rt>` The source register.

`<Rn>` The base register. The SP can be used. In the ARM instruction set, for offset addressing only, the PC can be used. However, ARM deprecates use of the PC.

`+/-` Is + or omitted if the optionally shifted value of `<Rm>` is to be added to the base register value (`add == TRUE`), or – if it is to be subtracted (permitted in ARM instructions only, `add == FALSE`).

`<Rm>` Contains the offset that is optionally left shifted and added to the value of `<Rn>` to form the address.

`<imm>` If present, the size of the left shift to apply to the value from `<Rm>`, in the range 1-3. Only encoding T2 is permitted, and `<imm>` is encoded in imm2.

If absent, no shift is specified and all encodings are permitted. In encoding T2, imm2 is encoded as `0b00`.

The pre-UAL syntax `STR<c>H` is equivalent to `STRH<c>`.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  NullCheckIfThumbEE(n);
    offset = Shift(R[m], shift_t, shift_n, APSR.C);
    offset_addr = if add then (R[n] + offset) else (R[n] - offset);
    address = if index then offset_addr else R[n];
    if UnalignedSupport() || address<0> == '0' then
        MemU[address,2] = R[t]<15:0>;
    else // Can only occur before ARMv7
        MemU[address,2] = bits(16) UNKNOWN;
    if wback then R[n] = offset_addr;
```

Exceptions

Data Abort.

A8.8.219 STRHT

Store Register Halfword Unprivileged stores a halfword from a register to memory. For information about memory accesses see *Memory accesses* on page A8-294.

The memory access is restricted as if the processor were running in User mode. This makes no difference if the processor is actually running in User mode.

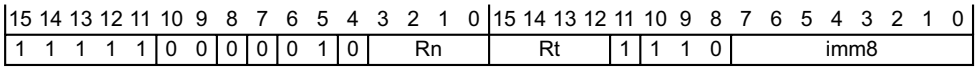
STRHT is UNPREDICTABLE in Hyp mode.

The Thumb instruction uses an offset addressing mode, that calculates the address used for the memory access from a base register value and an immediate offset, and leaves the base register unchanged.

The ARM instruction uses a post-indexed addressing mode, that uses a base register value as the address for the memory access, and calculates a new address from a base register value and an offset and writes it back to the base register. The offset can be an immediate value or a register value.

Encoding T1 ARMv6T2, ARMv7

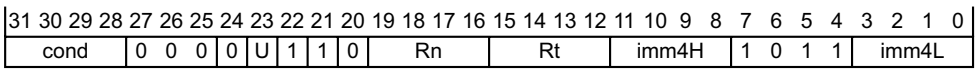
```
STRHT<c> <Rt>, [<Rn>, #<imm8>]
```



```
if Rn == '1111' then UNDEFINED;
t = UInt(Rt);  n = UInt(Rn);  postindex = FALSE;  add = TRUE;
register_form = FALSE;  imm32 = ZeroExtend(imm8, 32);
if t IN {13,15} then UNPREDICTABLE;
```

Encoding A1 ARMv6T2, ARMv7

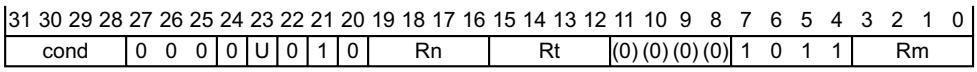
```
STRHT<c> <Rt>, [<Rn>] {, #+/-<imm8>}
```



```
t = UInt(Rt);  n = UInt(Rn);  postindex = TRUE;  add = (U == '1');
register_form = FALSE;  imm32 = ZeroExtend(imm4H:imm4L, 32);
if t == 15 || n == 15 || n == t then UNPREDICTABLE;
```

Encoding A2 ARMv6T2, ARMv7

```
STRHT<c> <Rt>, [<Rn>], +/-<Rm>
```



```
t = UInt(Rt);  n = UInt(Rn);  m = UInt(Rm);  postindex = TRUE;  add = (U == '1');
register_form = TRUE;
if t == 15 || n == 15 || n == t || m == 15 then UNPREDICTABLE;
```

Assembler syntax

`STRHT{<c>}{<q>}  <Rt>, [<Rn> {, #<imm>}]`	Offset: Thumb only
`STRHT{<c>}{<q>}  <Rt>, [<Rn>] {, #+/-<imm>}`	Post-indexed: ARM only
`STRHT{<c>}{<q>}  <Rt>, [<Rn>], +/-<Rm>`	Post-indexed: ARM only

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287.

`<Rt>` The source register.

`<Rn>` The base register. The SP can be used.

`+/-` Is + or omitted if `<imm>` or the optionally shifted value of `<Rm>` is to be added to the base register value (`add == TRUE`), or – if it is to be subtracted (permitted in ARM instructions only, `add == FALSE`).

`<imm>` The immediate offset applied to the value of `<Rn>`. Any value in the range 0-255 is permitted. `<imm>` can be omitted, meaning an offset of 0.

`<Rm>` Contains the offset that is applied to the value of `<Rn>` to form the address.

Operation

```
if ConditionPassed() then
    if CurrentModeIsHyp() then UNPREDICTABLE;               // Hyp mode
    EncodingSpecificOperations();  NullCheckIfThumbEE(n);
    offset = if register_form then R[m] else imm32;
    offset_addr = if add then (R[n] + offset) else (R[n] - offset);
    address = if postindex then R[n] else offset_addr;
    if UnalignedSupport() || address<0> == '0' then
        MemU_unpriv[address,2] = R[t]<15:0>;
    else // Can only occur before ARMv7
        MemU_unpriv[address,2] = bits(16) UNKNOWN;
    if postindex then R[n] = offset_addr;
```

Exceptions

Data Abort.

A8.8.220 STRT

Store Register Unprivileged stores a word from a register to memory. For information about memory accesses see *Memory accesses* on page A8-294.

The memory access is restricted as if the processor were running in User mode. This makes no difference if the processor is actually running in User mode.

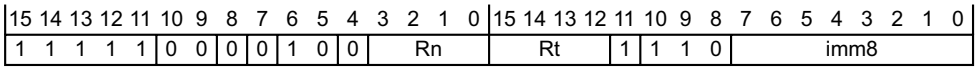
STRT is UNPREDICTABLE in Hyp mode.

The Thumb instruction uses an offset addressing mode, that calculates the address used for the memory access from a base register value and an immediate offset, and leaves the base register unchanged.

The ARM instruction uses a post-indexed addressing mode, that uses a base register value as the address for the memory access, and calculates a new address from a base register value and an offset and writes it back to the base register. The offset can be an immediate value or an optionally-shifted register value.

Encoding T1 ARMv6T2, ARMv7

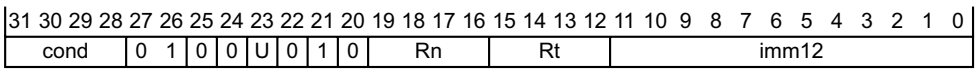
```
STRT<c> <Rt>, [<Rn>, #<imm8>]
```



```
if Rn == '1111' then UNDEFINED;
t = UInt(Rt);  n = UInt(Rn);  postindex = FALSE;  add = TRUE;
register_form = FALSE;  imm32 = ZeroExtend(imm8, 32);
if t IN {13,15} then UNPREDICTABLE;
```

Encoding A1 ARMv4*, ARMv5T*, ARMv6*, ARMv7

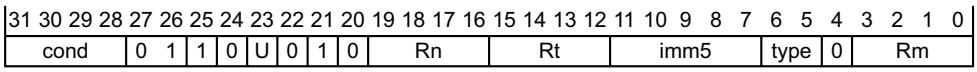
```
STRT<c> <Rt>, [<Rn>] {, +/-<imm12>}
```



```
t = UInt(Rt);  n = UInt(Rn);  postindex = TRUE;  add = (U == '1');
register_form = FALSE;  imm32 = ZeroExtend(imm12, 32);
if n == 15 || n == t then UNPREDICTABLE;
```

Encoding A2 ARMv4*, ARMv5T*, ARMv6*, ARMv7

```
STRT<c> <Rt>, [<Rn>],+/-<Rm>{, <shift>}
```



```
t = UInt(Rt);  n = UInt(Rn);  m = UInt(Rm);  postindex = TRUE;  add = (U == '1');
register_form = TRUE;  (shift_t, shift_n) = DecodeImmShift(type, imm5);
if n == 15 || n == t || m == 15 then UNPREDICTABLE;
if ArchVersion() < 6 && m == n then UNPREDICTABLE;
```

Assembler syntax

`STRT{<c>}{<q>}  <Rt>, [<Rn> {, #<imm>}]`	Offset: Thumb only
`STRT{<c>}{<q>}  <Rt>, [<Rn>] {, #+/-<imm>}`	Post-indexed: ARM only
`STRT{<c>}{<q>}  <Rt>, [<Rn>], +/-<Rm> {, <shift>}`	Post-indexed: ARM only

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287.

`<Rt>` The source register. In the ARM instruction set, the PC can be used. However, ARM deprecates use of the PC.

`<Rn>` The base register. The SP can be used.

`+/-` Is + or omitted if `<imm>` or the optionally shifted value of `<Rm>` is to be added to the base register value (`add == TRUE`), or – if it is to be subtracted (permitted in ARM instructions only, `add == FALSE`).

`<imm>` The immediate offset applied to the value of `<Rn>`. Values are 0-255 for encoding T1, and 0-4095 for encoding A1. `<imm>` can be omitted, meaning an offset of 0.

`<Rm>` Contains the offset that is optionally shifted and added to the value of `<Rn>` to form the address.

`<shift>` The shift to apply to the value read from `<Rm>`. If omitted, no shift is applied. *Shifts applied to a register* on page A8-291 describes the shifts and how they are encoded.

The pre-UAL syntax `STR<c>T` is equivalent to `STRT<c>`.

Operation

```
if ConditionPassed() then
    if CurrentModeIsHyp() then UNPREDICTABLE;               // Hyp mode
    EncodingSpecificOperations();  NullCheckIfThumbEE(n);

    offset_addr = if add then (R[n] + offset) else (R[n] - offset);
    address = if postindex then R[n] else offset_addr;
    if t == 15 then  // Only possible for encodings A1 and A2
        data = PCStoreValue();
    else
        data = R[t];
    if UnalignedSupport() || address<1:0> == '00' || CurrentInstrSet() == InstrSet_ARM then
        MemU_unpriv[address,4] = data;
    else // Can only occur before ARMv7
        MemU_unpriv[address,4] = bits(32) UNKNOWN;
    if postindex then R[n] = offset_addr;
```

Exceptions

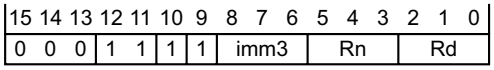
Data Abort.

A8.8.221 SUB (immediate, Thumb)

This instruction subtracts an immediate value from a register value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

Encoding T1 ARMv4T, ARMv5T*, ARMv6*, ARMv7

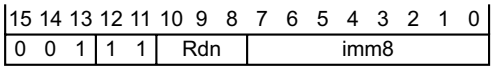
```
SUBS <Rd>, <Rn>, #<imm3>                    Outside IT block.
SUB<c> <Rd>, <Rn>, #<imm3>                  Inside IT block.
```



```
d = UInt(Rd);  n = UInt(Rn);  setflags = !InITBlock();  imm32 = ZeroExtend(imm3, 32);
```

Encoding T2 ARMv4T, ARMv5T*, ARMv6*, ARMv7

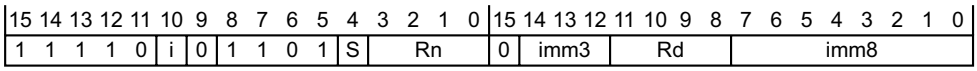
```
SUBS <Rdn>, #<imm8>                         Outside IT block.
SUB<c> <Rdn>, #<imm8>                       Inside IT block.
```



```
d = UInt(Rdn);  n = UInt(Rdn);  setflags = !InITBlock();  imm32 = ZeroExtend(imm8, 32);
```

Encoding T3 ARMv6T2, ARMv7

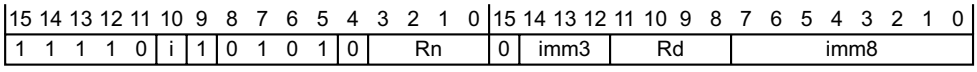
```
SUB{S}<c>.W <Rd>, <Rn>, #<const>
```



```
if Rd == '1111' && S == '1' then SEE CMP (immediate);
if Rn == '1101' then SEE SUB (SP minus immediate);
d = UInt(Rd);  n = UInt(Rn);  setflags = (S == '1');  imm32 = ThumbExpandImm(i:imm3:imm8);
if d == 13 || (d == 15 && S == '0') || n == 15 then UNPREDICTABLE;
```

Encoding T4 ARMv6T2, ARMv7

```
SUBW<c> <Rd>, <Rn>, #<imm12>
```



```
if Rn == '1111' then SEE ADR;
if Rn == '1101' then SEE SUB (SP minus immediate);
d = UInt(Rd);  n = UInt(Rn);  setflags = FALSE;  imm32 = ZeroExtend(i:imm3:imm8, 32);
if d IN {13,15} then UNPREDICTABLE;
```

Assembler syntax

`SUB{S}{<c>}{<q>}  {<Rd>,} <Rn>, #<const>`	All encodings permitted
`SUBW{<c>}{<q>}  {<Rd>,} <Rn>, #<const>`	Only encoding T4 permitted

where:

`S` If `S` is present, the instruction updates the flags. Otherwise, the flags are not updated.

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287.

`<Rd>` The destination register. If `S` is specified and `<Rd>` is the PC, see *SUBS PC, LR (Thumb)* on page B9-2008 or *SUBS PC, LR and related instructions (ARM)* on page B9-2010.

`<Rn>` The first operand register. If the SP is specified for `<Rn>`, see *SUB (SP minus immediate)* on page A8-716. If the PC is specified for `<Rn>`, see *ADR* on page A8-322.

`<const>` The immediate value to be subtracted from the value obtained from `<Rn>`. The range of values is 0-7 for encoding T1, 0-255 for encoding T2 and 0-4095 for encoding T4. See *Modified immediate constants in Thumb instructions* on page A6-232 for the range of values for encoding T3.

When multiple encodings of the same length are available for an instruction, encoding T3 is preferred to encoding T4. If encoding T4 is required, use the `SUBW` syntax. Encoding T1 is preferred to encoding T2 if `<Rd>` is specified and encoding T2 is preferred to encoding T1 if `<Rd>` is omitted.

The pre-UAL syntax `SUB<c>S` is equivalent to `SUBS<c>`.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    (result, carry, overflow) = AddWithCarry(R[n], NOT(imm32), '1');
    R[d] = result;
    if setflags then
        APSR.N = result<31>;
        APSR.Z = IsZeroBit(result);
        APSR.C = carry;
        APSR.V = overflow;
```

Exceptions

None.

A8.8.222 SUB (immediate, ARM)

(shift_t, shift_n) = DecodeImmShift(type, imm5);
```

Assembler syntax

```
SUB{S}{<c>}{<q>}  {<Rd>,} <Rn>, <Rm> {, <shift>}
```

where:

S — If S is present, the instruction updates the flags. Otherwise, the flags are not updated.

<c>, <q> — See *Standard assembler syntax fields* on page A8-287.

<Rd> — The destination register. If S is specified and <Rd> is the PC, see *SUBS PC, LR (Thumb)* on page B9-2008 or *SUBS PC, LR and related instructions (ARM)* on page B9-2010.

In ARM instructions, if S is not specified and <Rd> is the PC, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode details of operations on ARM core registers* on page A2-47.

Note

Before ARMv7, this was a simple branch.

<Rn> — The first operand register. The PC can be used in ARM instructions. If the SP is specified for <Rn>, see *SUB (SP minus register)* on page A8-718.

<Rm> — The register that is optionally shifted and used as the second operand. The PC can be used in ARM instructions.

<shift> — The shift to apply to the value read from <Rm>. If present, encoding T1 is not permitted. If absent, no shift is applied and all encodings are permitted. *Shifts applied to a register* on page A8-291 describes the shifts and how they are encoded.

The pre-UAL syntax SUB<c>S is equivalent to SUBS<c>.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shifted = Shift(R[m], shift_t, shift_n, APSR.C);
    (result, carry, overflow) = AddWithCarry(R[n], NOT(shifted), '1');
    if d == 15 then          // Can only occur for ARM encoding
        ALUWritePC(result);  // setflags is always FALSE here
    else
        R[d] = result;
        if setflags then
            APSR.N = result<31>;
            APSR.Z = IsZeroBit(result);
            APSR.C = carry;
            APSR.V = overflow;
```

Exceptions

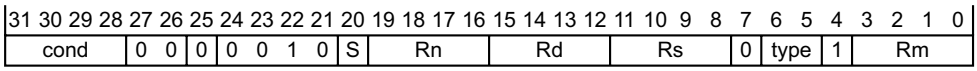
None.

A8.8.224 SUB (register-shifted register)

This instruction subtracts a register-shifted register value from a register value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

Encoding A1 ARMv4*, ARMv5T*, ARMv6*, ARMv7

```
SUB{S}<c> <Rd>, <Rn>, <Rm>, <type> <Rs>
```



31 30 29 28	27 26	25	24 23 22 21	20	19 18 17 16	15 14 13 12	11 10 9 8	7	6 5	4	3 2 1 0
cond	0 0	0	0 0 1 0	S	Rn	Rd	Rs	0	type	1	Rm

```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  s = UInt(Rs);
setflags = (S == '1');  shift_t = DecodeRegShift(type);
if d == 15 || n == 15 || m == 15 || s == 15 then UNPREDICTABLE;
```

Assembler syntax

```
SUB{S}{<c>}{<q>}  {<Rd>,} <Rn>, <Rm>, <type>  <Rs>
```

where:

S	If S is present, the instruction updates the flags. Otherwise, the flags are not updated.
<c>, <q>	See *Standard assembler syntax fields* on page A8-287.
<Rd>	The destination register.
<Rn>	The first operand register.
<Rm>	The register that is shifted and used as the second operand.
<type>	The type of shift to apply to the value read from <Rm>. It must be one of: ASR — Arithmetic shift right, encoded as type = 0b10. LSL — Logical shift left, encoded as type = 0b00. LSR — Logical shift right, encoded as type = 0b01. ROR — Rotate right, encoded as type = 0b11.
<Rs>	The register whose bottom byte contains the amount to shift by.

The pre-UAL syntax SUB<c>S is equivalent to SUBS<c>.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shift_n = UInt(R[s]<7:0>);
    shifted = Shift(R[m], shift_t, shift_n, APSR.C);
    (result, carry, overflow) = AddWithCarry(R[n], NOT(shifted), '1');
    R[d] = result;
    if setflags then
        APSR.N = result<31>;
        APSR.Z = IsZeroBit(result);
        APSR.C = carry;
        APSR.V = overflow;
```

Exceptions

None.

A8.8.225 SUB (SP minus immediate)

This instruction subtracts an immediate value from the SP value, and writes the result to the destination register.

Encoding T1 ARMv4T, ARMv5T*, ARMv6*, ARMv7

```
SUB<c> SP, SP, #<imm>
```

```

Assembler syntax

`SUB{S}{<c>}{<q>}  {<Rd>,} SP, #<const>`	All encodings permitted
`SUBW{<c>}{<q>}  {<Rd>,} SP, #<const>`	Only encoding T3 permitted

where:

`S` If `S` is present, the instruction updates the flags. Otherwise, the flags are not updated.

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287.

`<Rd>` The destination register. If `S` is specified and `<Rd>` is the PC, see *SUBS PC, LR (Thumb)* on page B9-2008 or *SUBS PC, LR and related instructions (ARM)* on page B9-2010. If omitted, `<Rd>` is SP.

In ARM instructions, if `S` is not specified and `<Rd>` is the PC, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode details of operations on ARM core registers* on page A2-47.

Note

Before ARMv7, this was a simple branch.

`<const>` The immediate value to be subtracted from the value obtained from SP. Values are multiples of 4 in the range 0-508 for encoding T1 and any value in the range 0-4095 for encoding T3. See *Modified immediate constants in Thumb instructions* on page A6-232 or *Modified immediate constants in ARM instructions* on page A5-200 for the range of values for encodings T2 and A1.

When both 32-bit encodings are available for an instruction, encoding T2 is preferred to encoding T3 (if encoding T3 is required, use the `SUBW` syntax).

The pre-UAL syntax `SUB<c>S` is equivalent to `SUBS<c>`.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    (result, carry, overflow) = AddWithCarry(SP, NOT(imm32), '1');
    if d == 15 then          // Can only occur for ARM encoding
        ALUWritePC(result);  // setflags is always FALSE here
    else
        R[d] = result;
        if setflags then
            APSR.N = result<31>;
            APSR.Z = IsZeroBit(result);
            APSR.C = carry;
            APSR.V = overflow;
```

Exceptions

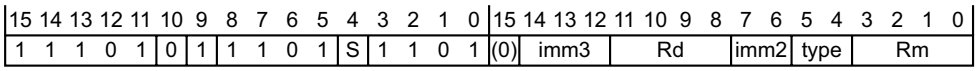
None.

A8.8.226 SUB (SP minus register)

This instruction subtracts an optionally-shifted register value from the SP value, and writes the result to the destination register.

Encoding T1 ARMv6T2, ARMv7

```
SUB{S}<c> <Rd>, SP, <Rm>{, <shift>}
```

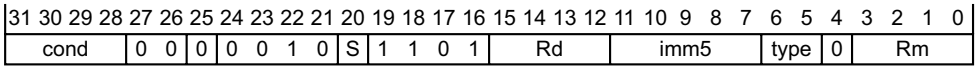


15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	0	1	0	1	1	1	0	1	S	1	1	0	1	(0)	imm3			Rd				imm2		type		Rm			

```
if Rd == '1111' && S == '1' then SEE CMP (register);
d = UInt(Rd);  m = UInt(Rm);  setflags = (S == '1');
(shift_t, shift_n) = DecodeImmShift(type, imm3:imm2);
if d == 13 && (shift_t != SRType_LSL || shift_n > 3) then UNPREDICTABLE;
if (d == 15 && S == '0') || m IN {13,15} then UNPREDICTABLE;
```

Encoding A1 ARMv4*, ARMv5T*, ARMv6*, ARMv7

```
SUB{S}<c> <Rd>, SP, <Rm>{, <shift>}
```



31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond				0	0	0	0	0	1	0	S	1	1	0	1	Rd				imm5					type		0	Rm			

```
if Rd == '1111' && S == '1' then SEE SUBS PC, LR and related instructions;
d = UInt(Rd);  m = UInt(Rm);  setflags = (S == '1');
(shift_t, shift_n) = DecodeImmShift(type, imm5);
```

Assembler syntax

```
SUB{S}{<c>}{<q>}  {<Rd>,} SP, <Rm> {, <shift>}
```

where:

S — If S is present, the instruction updates the flags. Otherwise, the flags are not updated.

<c><q> — See *Standard assembler syntax fields* on page A8-287.

<Rd> — The destination register. If S is specified and <Rd> is the PC, see *SUBS PC, LR (Thumb)* on page B9-2008 or *SUBS PC, LR and related instructions (ARM)* on page B9-2010. If omitted, <Rd> is SP.

In ARM instructions, if S is not specified and <Rd> is the PC, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode details of operations on ARM core registers* on page A2-47.

Note

Before ARMv7, this was a simple branch.

<Rm> — The register that is optionally shifted and used as the second operand. The PC can be used in ARM instructions.

<shift> — The shift to apply to the value read from <Rm>. If omitted, no shift is applied. *Shifts applied to a register* on page A8-291 describes the shifts and how they are encoded.

In the Thumb instruction set, if <Rd> is SP or omitted, <shift> is only permitted to be omitted, LSL #1, LSL #2, or LSL #3.

The pre-UAL syntax SUB<c>S is equivalent to SUBS<c>.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shifted = Shift(R[m], shift_t, shift_n, APSR.C);
    (result, carry, overflow) = AddWithCarry(SP, NOT(shifted), '1');
    if d == 15 then          // Can only occur for ARM encoding
        ALUWritePC(result);  // setflags is always FALSE here
    else
        R[d] = result;
        if setflags then
            APSR.N = result<31>;
            APSR.Z = IsZeroBit(result);
            APSR.C = carry;
            APSR.V = overflow;
```

Exceptions

None.

A8.8.227 SUBS PC, LR and related instructions

These instructions are for system level use only. See *SUBS PC, LR (Thumb)* on page B9-2008 and *SUBS PC, LR and related instructions (ARM)* on page B9-2010.

A8.8.228 SVC (previously SWI)

Supervisor Call, previously called Software Interrupt, causes a Supervisor Call exception. For more information, see *Supervisor Call (SVC) exception* on page B1-1209.

Software can use this instruction as a call to an operating system to provide a service.

In the following cases, the Supervisor Call exception generated by the SVC instruction is taken to Hyp mode:

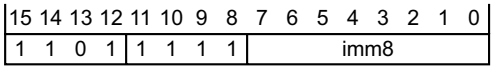
- If the SVC is executed in Hyp mode.
- If HCR.TGE is set to 1, and the SVC is executed in Non-secure User mode. For more information, see *Supervisor Call exception, when HCR.TGE is set to 1* on page B1-1191

In these cases, the HSR identifies that the exception entry was caused by a Supervisor Call exception, EC value 0x11, see *Use of the HSR* on page B3-1424. The immediate field in the HSR:

- if the SVC is unconditional:
  - for the Thumb instruction, is the zero-extended value of the imm8 field
  - for the ARM instruction, is the least-significant 16 bits the imm24 field
- if the SVC is conditional, is UNKNOWN.

Encoding T1 ARMv4T, ARMv5T*, ARMv6*, ARMv7

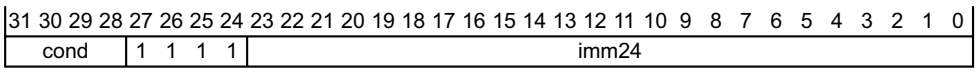
```
SVC<c> #<imm8>
```



```
imm32 = ZeroExtend(imm8, 32);
// imm32 is for assembly/disassembly. SVC handlers in some
// systems interpret imm8 in software, for example to determine the required service.
```

Encoding A1 ARMv4*, ARMv5T*, ARMv6*, ARMv7

```
SVC<c> #<imm24>
```



```
imm32 = ZeroExtend(imm24, 32);
// imm32 is for assembly/disassembly. SVC handlers in some
// systems interpret imm24 in software, for example to determine the required service.
```

Assembler syntax

```
SVC{<c>}{<q>}  {#}<imm>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287.

`<imm>` Specifies an immediate constant, 8-bit in Thumb instructions, or 24-bit in ARM instructions.

The pre-UAL syntax `SWI<c>` is equivalent to `SVC<c>`.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CallSupervisor(imm32<15:0>);
```

Exceptions

Supervisor Call.

A8.8.229 SWP, SWPB

SWP (Swap) swaps a word between registers and memory. SWP loads a word from the memory address given by the value of register <Rn>. The value of register <Rt2> is then stored to the memory address given by the value of <Rn>, and the original loaded value is written to register <Rt>. If the same register is specified for <Rt> and <Rt2>, this instruction swaps the value of the register and the value at the memory address.

SWPB (Swap Byte) swaps a byte between registers and memory. SWPB loads a byte from the memory address given by the value of register <Rn>. The value of the least significant byte of register <Rt2> is stored to the memory address given by <Rn>, the original loaded value is zero-extended to a 32-bit word, and the word is written to register <Rt>. If the same register is specified for <Rt> and <Rt2>, this instruction swaps the value of the least significant byte of the register and the byte value at the memory address, and clears the most significant three bytes of the register.

For both instructions, the memory system ensures that no other memory access can occur to the memory location between the load access and the store access.

Note

- The SWP and SWPB instructions rely on the properties of the system beyond the processor to ensure that no stores from other observers can occur between the load access and the store access, and this might not be implemented for all regions of memory on some system implementations. In all cases, SWP and SWPB do ensure that no stores from the processor that executed the SWP or SWPB instruction can occur between the load access and the store access of the SWP or SWPB.
- ARM deprecates the use of SWP and SWPB, and strongly recommends that new software uses:
  - LDREX/STREX in preference to SWP
  - LDREXB/STREXB in preference to SWPB.
- If the translation table entries that relate to a memory location accessed by the SWP or SWPB instruction change, or are seen to change by the executing processor as a result of TLB eviction, this might mean that the translation table attributes, permissions or addresses for the load are different to those for the store. In this case, the architecture makes no guarantee that no memory access occur to these memory locations between the load and store.

The Virtualization Extensions make the SWP and SWPB instructions OPTIONAL and deprecated:

- If an implementation does not include the SWP and SWPB instructions, the ID_ISAR0.Swap_instrs and ID_ISAR4.SWP_frac fields are zero, see *About the Instruction Set Attribute registers* on page B7-1950.
- In an implementation that includes SWP and SWPB, both instructions are UNDEFINED in Hyp mode.

Encoding A1 ARMv4*, ARMv5T*, deprecated in ARMv6* and ARMv7, OPTIONAL in ARMv7VE

```
SWP{B}<c> <Rt>, <Rt2>, [<Rn>]
```

31 30 29 28	27 26 25 24 23	22	21 20	19 18 17 16	15 14 13 12	11 10 9 8	7 6 5 4	3 2 1 0
cond	0 0 0 1 0	B	0 0	Rn	Rt	(0) (0) (0) (0)	1 0 0 1	Rt2

```
t = UInt(Rt);  t2 = UInt(Rt2);  n = UInt(Rn);  size = if B == '1' then 1 else 4;
if t == 15 || t2 == 15 || n == 15 || n == t || n == t2 then UNPREDICTABLE;
```

Assembler syntax

```
SWP{B}{<c>}{<q>}  <Rt>, <Rt2>, [<Rn>]
```

where:

B	If B is present, the instruction operates on a byte. Otherwise, it operates on a word.
<c>, <q>	See *Standard assembler syntax fields* on page A8-287.
<Rt>	The destination register.
<Rt2>	Contains the value that is stored to memory.
<Rn>	Contains the memory address to load from.

The pre-UAL syntax SWP<c>B is equivalent to SWPB<c>.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if CurrentModeIsHyp() then UNDEFINED;
    // The MemA[] accesses in the next two statements are locked together, that is, the memory
    // system must ensure that no other access to the same location can occur between them.
    data = MemA[R[n], size];
    MemA[R[n], size] = R[t2]<8*size-1:0>;
    if size == 1 then  // SWPB
        R[t] = ZeroExtend(data, 32);
    else               // SWP
        // Rotation in the following will always be by zero in ARMv7, due to alignment checks,
        // but can be nonzero in legacy configurations.
        R[t] = ROR(data, 8*UInt(R[n]<1:0>));
```

Exceptions

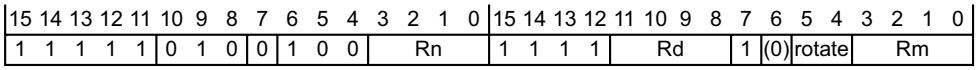
Data Abort.

A8.8.230 SXTAB

Signed Extend and Add Byte extracts an 8-bit value from a register, sign-extends it to 32 bits, adds the result to the value in another register, and writes the final result to the destination register. The instruction can specify a rotation by 0, 8, 16, or 24 bits before extracting the 8-bit value.

Encoding T1 ARMv6T2, ARMv7

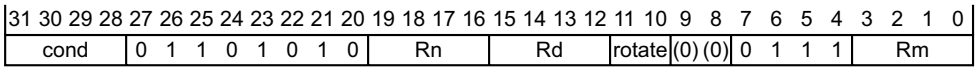
```
SXTAB<c> <Rd>, <Rn>, <Rm>{, <rotation>}
```



```
if Rn == '1111' then SEE SXTB;
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  rotation = UInt(rotate:'000');
if d IN {13,15} || n == 13 || m IN {13,15} then UNPREDICTABLE;
```

Encoding A1 ARMv6*, ARMv7

```
SXTAB<c> <Rd>, <Rn>, <Rm>{, <rotation>}
```



```
if Rn == '1111' then SEE SXTB;
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  rotation = UInt(rotate:'000');
if d == 15 || m == 15 then UNPREDICTABLE;
```

Assembler syntax

```
SXTAB{<c>}{<q>}  {<Rd>,} <Rn>, <Rm> {, <rotation>}
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287.

`<Rd>` The destination register.

`<Rn>` The first operand register.

`<Rm>` The second operand register.

`<rotation>` This can be any one of:

omitted	encoded as rotate = `0b00`
`ROR #8`	encoded as rotate = `0b01`
`ROR #16`	encoded as rotate = `0b10`
`ROR #24`	encoded as rotate = `0b11`.

Note

An assembler can permit `ROR #0` to mean the same thing as omitting the rotation, possibly with restrictions on the permitted encodings, but this is not standard UAL and must not be used for disassembly.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    rotated = ROR(R[m], rotation);
    R[d] = R[n] + SignExtend(rotated<7:0>, 32);
```

Exceptions

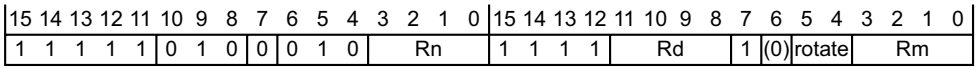
None.

A8.8.231 SXTAB16

Signed Extend and Add Byte 16 extracts two 8-bit values from a register, sign-extends them to 16 bits each, adds the results to two 16-bit values from another register, and writes the final results to the destination register. The instruction can specify a rotation by 0, 8, 16, or 24 bits before extracting the 8-bit values.

Encoding T1 ARMv6T2, ARMv7

```
SXTAB16<c> <Rd>, <Rn>, <Rm>{, <rotation>}
```



```
if Rn == '1111' then SEE SXTB16;

```
d = UInt(Rd);  m = UInt(Rm);  rotation = UInt(rotate:'000');
if d IN {13,15} || m IN {13,15} then UNPREDICTABLE;
```

Encoding A1 ARMv6*, ARMv7

```
SXTB16<c> <Rd>, <Rm>{, <rotation>}
```

```
d = UInt(Rd);  m = UInt(Rm);  rotation = UInt(rotate:'000');
if d == 15 || m == 15 then UNPREDICTABLE;
```

Assembler syntax

```
SXTB16{<c>}{<q>}  {<Rd>,} <Rm> {, <rotation>}
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287.

`<Rd>` The destination register.

`<Rm>` The register that contains the operand.

`<rotation>` This can be any one of:

omitted	encoded as rotate = `0b00`
`ROR #8`	encoded as rotate = `0b01`
`ROR #16`	encoded as rotate = `0b10`
`ROR #24`	encoded as rotate = `0b11`.

Note

An assembler can permit `ROR #0` to mean the same thing as omitting the rotation, possibly with restrictions on the permitted encodings, but this is not standard UAL and must not be used for disassembly.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    rotated = ROR(R[m], rotation);
    R[d]<15:0>  = SignExtend(rotated<7:0>, 16);
    R[d]<31:16> = SignExtend(rotated<23:16>, 16);
```

Exceptions

None.

A8.8.235 SXTH

Signed Extend Halfword extracts a 16-bit value from a register, sign-extends it to 32 bits, and writes the result to the destination register. The instruction can specify a rotation by 0, 8, 16, or 24 bits before extracting the 16-bit value.

Encoding T1 ARMv6*, ARMv7

```
SXTH<c> <Rd>, <Rm>
```

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

d = UInt(Rd);  m = UInt(Rm);  rotation = UInt(rotate:'000');
if d == 15 || m == 15 then UNPREDICTABLE;
```

Assembler syntax

```
SXTH{<c>}{<q>}  {<Rd>,} <Rm> {, <rotation>}
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287.

`<Rd>` The destination register.

`<Rm>` The register that contains the operand.

`<rotation>` This can be any one of:

omitted	any encoding, encoded as rotate = `0b00` in encoding T2 or A1
`ROR #8`	encoding T2 or A1, encoded as rotate = `0b01`
`ROR #16`	encoding T2 or A1, encoded as rotate = `0b10`
`ROR #24`	encoding T2 or A1, encoded as rotate = `0b11`.

Note

An assembler can permit `ROR #0` to mean the same thing as omitting the rotation, possibly with restrictions on the permitted encodings, but this is not standard UAL and must not be used for disassembly.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    rotated = ROR(R[m], rotation);
    R[d] = SignExtend(rotated<15:0>, 32);
```

Exceptions

None.

A8.8.236 TBB, TBH

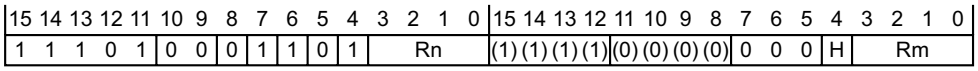
Table Branch Byte causes a PC-relative forward branch using a table of single byte offsets. A base register provides a pointer to the table, and a second register supplies an index into the table. The branch length is twice the value of the byte returned from the table.

Table Branch Halfword causes a PC-relative forward branch using a table of single halfword offsets. A base register provides a pointer to the table, and a second register supplies an index into the table. The branch length is twice the value of the halfword returned from the table.

Encoding T1 ARMv6T2, ARMv7

`TBB<c> [<Rn>, <Rm>]` Outside or last in IT block

`TBH<c> [<Rn>, <Rm>, LSL #1]` Outside or last in IT block



```
n = UInt(Rn);  m = UInt(Rm);  is_tbh = (H == '1');
if n == 13 || m IN {13,15} then UNPREDICTABLE;
if InITBlock() && !LastInITBlock() then UNPREDICTABLE;
```

Assembler syntax

```
TBB{<c>}{<q>}  [<Rn>, <Rm>]
TBH{<c>}{<q>}  [<Rn>, <Rm>, LSL #1]
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287.

`<Rn>` The base register. This contains the address of the table of branch lengths. The PC can be used. If it is, the table immediately follows this instruction.

`<Rm>` The index register.

For `TBB`, this contains an integer pointing to a single byte in the table. The offset in the table is the value of the index.

For `TBH`, this contains an integer pointing to a halfword in the table. The offset in the table is twice the value of the index.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  NullCheckIfThumbEE(n);
    if is_tbh then
        halfwords = UInt(MemU[R[n]+LSL(R[m],1), 2]);
    else
        halfwords = UInt(MemU[R[n]+R[m], 1]);
    BranchWritePC(PC + 2*halfwords);
```

Exceptions

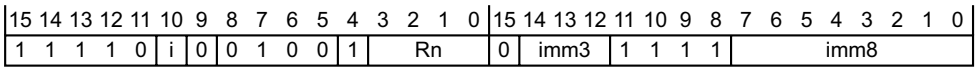
Data Abort.

A8.8.237 TEQ (immediate)

Test Equivalence (immediate) performs a bitwise exclusive OR operation on a register value and an immediate value. It updates the condition flags based on the result, and discards the result.

Encoding T1 ARMv6T2, ARMv7

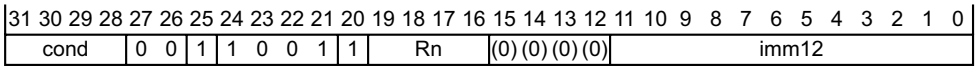
```
TEQ<c> <Rn>, #<const>
```



```
n = UInt(Rn);
(imm32, carry) = ThumbExpandImm_C(i:imm3:imm8, APSR.C);
if n IN {13,15} then UNPREDICTABLE;
```

Encoding A1 ARMv4*, ARMv5T*, ARMv6*, ARMv7

```
TEQ<c> <Rn>, #<const>
```



```
n = UInt(Rn);
(imm32, carry) = ARMExpandImm_C(imm12, APSR.C);
```

Assembler syntax

```
TEQ{<c>}{<q>}  <Rn>, #<const>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287.

`<Rn>` The operand register. The PC can be used in ARM instructions.

`<const>` The immediate value to be tested against the value obtained from `<Rn>`. See *Modified immediate constants in Thumb instructions* on page A6-232 or *Modified immediate constants in ARM instructions* on page A5-200 for the range of values.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    result = R[n] EOR imm32;
    APSR.N = result<31>;
    APSR.Z = IsZeroBit(result);
    APSR.C = carry;
    // APSR.V unchanged
```

Exceptions

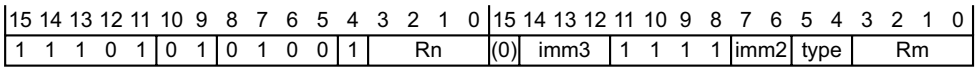
None.

A8.8.238 TEQ (register)

Test Equivalence (register) performs a bitwise exclusive OR operation on a register value and an optionally-shifted register value. It updates the condition flags based on the result, and discards the result.

Encoding T1 ARMv6T2, ARMv7

```
TEQ<c> <Rn>, <Rm>{, <shift>}
```



15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

```

Assembler syntax

```
TEQ{<c>}{<q>}  <Rn>, <Rm> {, <shift>}
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287.

`<Rn>` The first operand register. The PC can be used in ARM instructions.

`<Rm>` The register that is optionally shifted and used as the second operand. The PC can be used in ARM instructions.

`<shift>` The shift to apply to the value read from `<Rm>`. If omitted, no shift is applied. *Shifts applied to a register* on page A8-291 describes the shifts and how they are encoded.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    (shifted, carry) = Shift_C(R[m], shift_t, shift_n, APSR.C);
    result = R[n] EOR shifted;
    APSR.N = result<31>;
    APSR.Z = IsZeroBit(result);
    APSR.C = carry;
    // APSR.V unchanged
```

Exceptions

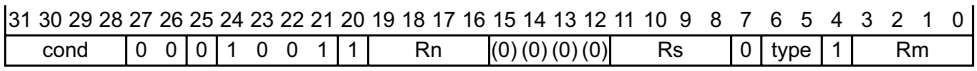
None.

A8.8.239 TEQ (register-shifted register)

Test Equivalence (register-shifted register) performs a bitwise exclusive OR operation on a register value and a register-shifted register value. It updates the condition flags based on the result, and discards the result.

Encoding A1 ARMv4*, ARMv5T*, ARMv6*, ARMv7

```
TEQ<c> <Rn>, <Rm>, <type> <Rs>
```



31 30 29 28	27 26	25	24 23 22 21	20	19 18 17 16	15 14 13 12	11 10 9 8	7	6 5	4	3 2 1 0

if n == 15 || m == 15 || s == 15 then UNPREDICTABLE;
```

Assembler syntax

```
TEQ{<c>}{<q>}  <Rn>, <Rm>, <type>  <Rs>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287.

`<Rn>` The first operand register.

`<Rm>` The register that is shifted and used as the second operand.

`<type>` The type of shift to apply to the value read from `<Rm>`. It must be one of:

- `ASR` Arithmetic shift right, encoded as type = `0b10`.
- `LSL` Logical shift left, encoded as type = `0b00`.
- `LSR` Logical shift right, encoded as type = `0b01`.
- `ROR` Rotate right, encoded as type = `0b11`.

`<Rs>` The register whose bottom byte contains the amount to shift by.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shift_n = UInt(R[s]<7:0>);
    (shifted, carry) = Shift_C(R[m], shift_t, shift_n, APSR.C);
    result = R[n] EOR shifted;
    APSR.N = result<31>;
    APSR.Z = IsZeroBit(result);
    APSR.C = carry;
    // APSR.V unchanged
```

Exceptions

None.

A8.8.240 TST (immediate)

Test (immediate) performs a bitwise AND operation on a register value and an immediate value. It updates the condition flags based on the result, and discards the result.

Encoding T1 ARMv6T2, ARMv7

```
TST<c> <Rn>, #<const>
```

    APSR.GE<3:2> = if sum  >= 0x10000 then '11' else '00';
```

Exceptions

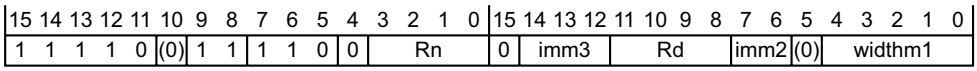
None.

A8.8.246 UBFX

Unsigned Bit Field Extract extracts any number of adjacent bits at any position from a register, zero-extends them to 32 bits, and writes the result to the destination register.

Encoding T1 ARMv6T2, ARMv7

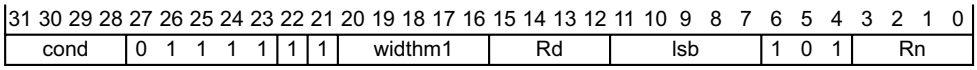
```
UBFX<c> <Rd>, <Rn>, #<lsb>, #<width>
```



```
d = UInt(Rd);  n = UInt(Rn);
lsbit = UInt(imm3:imm2);  widthminus1 = UInt(widthm1);
if d IN {13,15} || n IN {13,15} then UNPREDICTABLE;
```

Encoding A1 ARMv6T2, ARMv7

```
UBFX<c> <Rd>, <Rn>, #<lsb>, #<width>
```



```
d = UInt(Rd);  n = UInt(Rn);
lsbit = UInt(lsb);  widthminus1 = UInt(widthm1);
if d == 15 || n == 15 then UNPREDICTABLE;
```

Assembler syntax

```
UBFX{<c>}{<q>}  <Rd>, <Rn>, #<lsb>, #<width>
```

where:

`<c>, <q>`	See *Standard assembler syntax fields* on page A8-287.
`<Rd>`	The destination register.
`<Rn>`	The first operand register.
`<lsb>`	is the bit number of the least significant bit in the field, in the range 0-31. This determines the required value of `lsbit`.
`<width>`	is the width of the field, in the range 1 to 32-`<lsb>`. The required value of `widthminus1` is `<width>`-1.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    msbit = lsbit + widthminus1;
    if msbit <= 31 then
        R[d] = ZeroExtend(R[n]<msbit:lsbit>, 32);
    else
        UNPREDICTABLE;
```

Exceptions

None.

A8.8.247 UDF

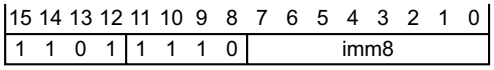
Permanently Undefined generates an Undefined Instruction exception.

The encodings for UDF used in this section are defined as permanently UNDEFINED in the versions of the architecture specified in this section. Issue C.a of this manual first defines an assembler mnemonic for these encodings. However:

- with the Thumb instruction set, ARM deprecates using the UDF instruction in an IT block
- in the ARM instruction set, UDF is not conditional.

Encoding T1 ARMv4T, ARMv5T*, ARMv6, ARMv7

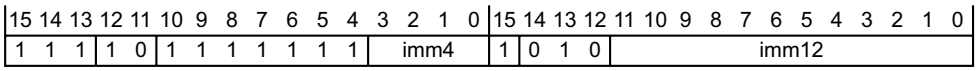
```
UDF<c> #<imm8>
```



```
imm32 = ZeroExtend(imm8, 32);
// imm32 is for assembly and disassembly only, and is ignored by hardware.
```

Encoding T2 ARMv6T2, ARMv7

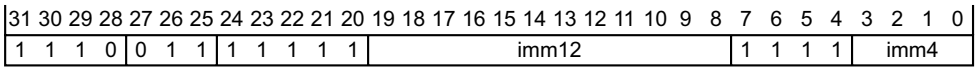
```
UDF<c>.W #<imm16>
```



```
imm32 = ZeroExtend(imm4:imm12, 32);
// imm32 is for assembly and disassembly only, and is ignored by hardware.
```

Encoding A1 ARMv4T, ARMv5T*, ARMv6, ARMv7

```
UDF<c> #<imm16>
```



```
imm32 = ZeroExtend(imm12:imm4, 32);
// imm32 is for assembly and disassembly only, and is ignored by hardware.
```

Assembler syntax

```
UDF{<c>}{<q>} {#}<imm>
```

where:

<c>, <q> See *Standard assembler syntax fields* on page A8-287.

In the ARM instruction set, <c> must be AL or omitted.

In the Thumb instruction set, ARM deprecates using any <c> value other than AL.

<imm> Specifies an immediate constant, that is 8-bit in encoding T1, and 16-bit in encodings T2 and A1. The processor ignores the value of this constant.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    UNDEFINED;
```

Exceptions

Undefined Instruction.

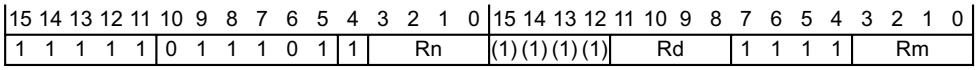
A8.8.248 UDIV

Unsigned Divide divides a 32-bit unsigned integer register value by a 32-bit unsigned integer register value, and writes the result to the destination register. The condition flags are not affected.

See *ARMv7 implementation requirements and options for the divide instructions* on page A4-172 for more information about this instruction.

Encoding T1 ARMv7-R, ARMv7VE, otherwise OPTIONAL in ARMv7-A

```
UDIV<c> <Rd>, <Rn>, <Rm>
```

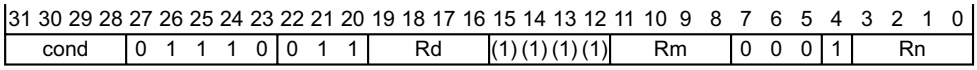


15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	1	0	1	1	1	0	1	1	Rn				(1)	(1)	(1)	(1)	Rd				1	1	1	1	Rm			

```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);
if d IN {13,15} || n IN {13,15} || m IN {13,15} then UNPREDICTABLE;
```

Encoding A1 ARMv7VE, otherwise OPTIONAL in ARMv7-A and ARMv7-R

```
UDIV<c> <Rd>, <Rn>, <Rm>
```



31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
cond				0	1	1	1	0	0	1	1	Rd				(1)	(1)	(1)	(1)	Rm				0	0	0	1	Rn			

```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE;
```

Assembler syntax

```
UDIV{<c>}{<q>}  {<Rd>,} <Rn>, <Rm>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287.

`<Rd>` The destination register.

`<Rn>` The register that contains the dividend.

`<Rm>` The register that contains the divisor.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if UInt(R[m]) == 0 then
        if IntegerZeroDivideTrappingEnabled() then
            GenerateIntegerZeroDivide();
        else
            result = 0;
    else
        result = RoundTowardsZero(UInt(R[n]) / UInt(R[m]));
    R[d] = result<31:0>;
```

Exceptions

In ARMv7-R profile, Undefined Instruction, see *Divide instructions* on page A4-172.

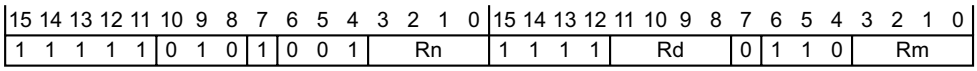
In ARMv7-A profile, none.

A8.8.249 UHADD16

Unsigned Halving Add 16 performs two unsigned 16-bit integer additions, halves the results, and writes the results to the destination register.

Encoding T1 ARMv6T2, ARMv7

```
UHADD16<c> <Rd>, <Rn>, <Rm>
```



15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

d = UInt(Rd);  n = UInt(Rn);  saturate_to = UInt(sat_imm);
(shift_t, shift_n) = DecodeImmShift(sh:'0', imm5);
if d == 15 || n == 15 then UNPREDICTABLE;
```

Assembler syntax

```
USAT{<c>}{<q>}  <Rd>, #<imm>, <Rn> {, <shift>}
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287.

`<Rd>` The destination register.

`<imm>` The bit position for saturation, in the range 0 to 31. This is encoded directly in the `sat_imm` field of the instruction, meaning `sat_imm` takes the value of `<imm>`.

`<Rn>` The register that contains the value to be saturated.

`<shift>` The optional shift, encoded in the sh bit and the `immsh` field, where `immsh` is:

- `imm3:imm2` for encoding T1
- `imm5` for encoding A1.

`<shift>` must be one of:

omitted No shift. Encoded as `sh` = 0, `immsh` = `0b00000`.

`LSL #<n>` Left shift by `<n>` bits, with `<n>` in the range 1-31.
Encoded as `sh` = 0, `immsh` = `<n>`.

`ASR #<n>` Arithmetic right shift by `<n>` bits, with `<n>` in the range 1-31.
Encoded as `sh` = 1, `immsh` = `<n>`.

`ASR #32` Arithmetic right shift by 32 bits, permitted only for encoding A1.
Encoded as `sh` = 1, `immsh` = `0b00000`.

Note

An assembler can permit `ASR #0` or `LSL #0` to mean the same thing as omitting the shift, but this is not standard UAL and must not be used for disassembly.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    operand = Shift(R[n], shift_t, shift_n, APSR.C);  // APSR.C ignored
    (result, sat) = UnsignedSatQ(SInt(operand), saturate_to);
    R[d] = ZeroExtend(result, 32);
    if sat then
        APSR.Q = '1';
```

Exceptions

None.

```
d = UInt(Rd);  n = UInt(Rn);  saturate_to = UInt(sat_imm);
if d == 15 || n == 15 then UNPREDICTABLE;
```

Assembler syntax

```
USAT16{<c>}{<q>}  <Rd>, #<imm>, <Rn>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287.

`<Rd>` The destination register.

`<imm>` The bit position for saturation, in the range 0 to 15. This is encoded directly in the `sat_imm` field of the instruction, meaning `sat_imm` takes the value of `<imm>`.

`<Rn>` The register that contains the values to be saturated.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    (result1, sat1) = UnsignedSatQ(SInt(R[n]<15:0>), saturate_to);
    (result2, sat2) = UnsignedSatQ(SInt(R[n]<31:16>), saturate_to);
    R[d]<15:0> = ZeroExtend(result1, 16);
    R[d]<31:16> = ZeroExtend(result2, 16);
    if sat1 || sat2 then
        APSR.Q = '1';
```

Exceptions

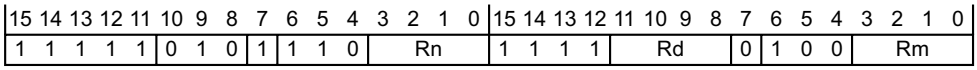
None.

A8.8.268 USAX

Unsigned Subtract and Add with Exchange exchanges the two halfwords of the second operand, performs one unsigned 16-bit integer subtraction and one unsigned 16-bit addition, and writes the results to the destination register. It sets the APSR.GE bits according to the results.

Encoding T1 ARMv6T2, ARMv7

```
USAX<c> <Rd>, <Rn>, <Rm>
```



```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);
if d IN {13,15} || n IN {13,15} || m IN {13,15} then UNPREDICTABLE;

A8.8.277 VABA, VABAL

Vector Absolute Difference and Accumulate {Long} subtracts the elements of one vector from the corresponding elements of another vector, and accumulates the absolute values of the results into the elements of the destination vector.

Operand and result elements are either all integers of the same length, or optionally the results can be double the length of the operands.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page B1-1232 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction that is not also available as a VFP instruction, see *Conditional execution* on page A8-288.

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287. An ARM `VABA` or `VABAL` instruction must be unconditional. ARM strongly recommends that a Thumb `VABA` or `VABAL` instruction is unconditional, see *Conditional execution* on page A8-288.

`<dt>` The data type for the elements of the operands. It must be one of:

- `S8` encoded as size = `0b00`, U = 0.
- `S16` encoded as size = `0b01`, U = 0.
- `S32` encoded as size = `0b10`, U = 0.
- `U8` encoded as size = `0b00`, U = 1.
- `U16` encoded as size = `0b01`, U = 1.
- `U32` encoded as size = `0b10`, U = 1.

`<Qd>, <Qn>, <Qm>` The destination vector and the operand vectors, for a quadword operation.

`<Dd>, <Dn>, <Dm>` The destination vector and the operand vectors, for a doubleword operation.

`<Qd>, <Dn>, <Dm>` The destination vector and the operand vectors, for a long operation.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        for e = 0 to elements-1
            op1 = Elem[Din[n+r],e,esize];
            op2 = Elem[Din[m+r],e,esize];
            absdiff = Abs(Int(op1,unsigned) - Int(op2,unsigned));
            if long_destination then
                Elem[Q[d>>1],e,2*esize] = Elem[Qin[d>>1],e,2*esize] + absdiff;
            else
                Elem[D[d+r],e,esize] = Elem[Din[d+r],e,esize] + absdiff;
```

Exceptions

Undefined Instruction, Hyp Trap.

A8.8.278 VABD, VABDL (integer)

Vector Absolute Difference {Long} (integer) subtracts the elements of one vector from the corresponding elements of another vector, and places the absolute values of the results in the elements of the destination vector.

Operand and result elements are either all integers of the same length, or optionally the results can be double the length of the operands.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page B1-1232 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction that is not also available as a VFP instruction, see *Conditional execution* on page A8-288.

            S[d] = FPAbs(S[m]);
```

Exceptions

Undefined Instruction, Hyp Trap.

A8.8.281 VACGE, VACGT, VACLE, VACLT

VACGE (Vector Absolute Compare Greater Than or Equal) and VACGT (Vector Absolute Compare Greater Than) take the absolute value of each element in a vector, and compare it with the absolute value of the corresponding element of a second vector. If the condition is true, the corresponding element in the destination vector is set to all ones. Otherwise, it is set to all zeros.

VACLE (Vector Absolute Compare Less Than or Equal) is a pseudo-instruction, equivalent to a VACGE instruction with the operands reversed. Disassembly produces the VACGE instruction.

VACLT (Vector Absolute Compare Less Than) is a pseudo-instruction, equivalent to a VACGT instruction with the operands reversed. Disassembly produces the VACGT instruction.

The operands and result can be quadword or doubleword vectors. They must all be the same size.

The operand vector elements must be 32-bit floating-point numbers.

The result vector elements are 32-bit fields.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page B1-1232 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction that is not also available as a VFP instruction, see *Conditional execution* on page A8-288.

        else
            S[d] = FPAdd(S[n], S[m], TRUE);
```

Exceptions

Undefined Instruction, Hyp Trap.

Floating-point exceptions

Input Denormal, Invalid Operation, Overflow, Underflow, Inexact.

A8.8.284 VADDHN

Vector Add and Narrow, returning High Half adds corresponding elements in two quadword vectors, and places the most significant half of each result in a doubleword vector. The results are truncated. (For rounded results, see *VRADDHN* on page A8-1022).

The operand elements can be 16-bit, 32-bit, or 64-bit integers. There is no distinction between signed and unsigned integers.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page B1-1232 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see *Conditional execution* on page A8-288.

esize = 8 << UInt(size);  elements = 64 DIV esize;
d = UInt(D:Vd);  n = UInt(N:Vn);  m = UInt(M:Vm);
```

Related encodings See *Advanced SIMD data-processing instructions* on page A7-261.

Assembler syntax

```
VADDHN{<c>}{<q>}.<dt>  <Dd>, <Qn>, <Qm>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287. An ARM `VADDHN` instruction must be unconditional.ARM strongly recommends that a Thumb `VADDHN` instruction is unconditional, see *Conditional execution* on page A8-288.

`<dt>` The data type for the elements of the operands. It must be one of:

- `I16` size = `0b00`.
- `I32` size = `0b01`.
- `I64` size = `0b10`.

`<Dd>, <Qn>, <Qm>` The destination vector, the first operand vector, and the second operand vector.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for e = 0 to elements-1
        result = Elem[Qin[n>>1],e,2*esize] + Elem[Qin[m>>1],e,2*esize];
        Elem[D[d],e,esize] = result<2*esize-1:esize>;
```

Exceptions

Undefined Instruction, Hyp Trap.

A8.8.285 VADDL, VADDW

VADDL (Vector Add Long) adds corresponding elements in two doubleword vectors, and places the results in a quadword vector. Before adding, it sign-extends or zero-extends the elements of both operands.

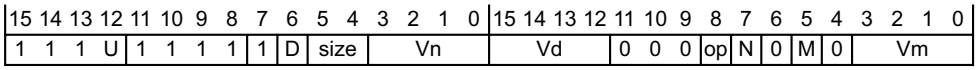
VADDW (Vector Add Wide) adds corresponding elements in one quadword and one doubleword vector, and places the results in a quadword vector. Before adding, it sign-extends or zero-extends the elements of the doubleword operand.

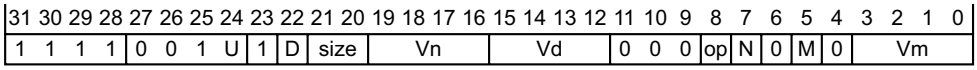
Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page B1-1232 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see *Conditional execution* on page A8-288.

Encoding T1/A1 Advanced SIMD

```
VADDL<c>.<dt> <Qd>, <Dn>, <Dm>
VADDW<c>.<dt> <Qd>, <Qn>, <Dm>
```





```
if size == '11' then SEE "Related encodings";
if Vd<0> == '1' || (op == '1' && Vn<0> == '1') then UNDEFINED;
unsigned = (U == '1');
esize = 8 << UInt(size);  elements = 64 DIV esize;  is_vaddw = (op == '1');
d = UInt(D:Vd);  n = UInt(N:Vn);  m = UInt(M:Vm);
```

Related encodings See *Advanced SIMD data-processing instructions* on page A7-261.

Assembler syntax

`VADDL{<c>}{<q>}.<dt>  <Qd>, <Dn>, <Dm>`	Encoded as op = 0
`VADDW{<c>}{<q>}.<dt>  {<Qd>,} <Qn>, <Dm>`	Encoded as op = 1

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287. An ARM `VADDL` or `VADDW` instruction must be unconditional. ARM strongly recommends that a Thumb `VADDL` or `VADDW` instruction is unconditional, see *Conditional execution* on page A8-288.

`<dt>` The data type for the elements of the second operand vector. It must be one of:

- `S8` encoded as size = `0b00`, U = 0.
- `S16` encoded as size = `0b01`, U = 0.
- `S32` encoded as size = `0b10`, U = 0.
- `U8` encoded as size = `0b00`, U = 1.
- `U16` encoded as size = `0b01`, U = 1.
- `U32` encoded as size = `0b10`, U = 1.

`<Qd>` The destination register. If this register is omitted in a `VADDW` instruction, it is the same register as `<Qn>`.

`<Qn>, <Dm>` The first and second operand registers for a `VADDW` instruction.

`<Dn>, <Dm>` The first and second operand registers for a `VADDL` instruction.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for e = 0 to elements-1
        if is_vaddw then
            op1 = Int(Elem[Qin[n>>1],e,2*esize], unsigned);
        else
            op1 = Int(Elem[Din[n],e,esize], unsigned);
        result = op1 + Int(Elem[Din[m],e,esize],unsigned);
        Elem[Q[d>>1],e,2*esize] = result<2*esize-1:0>;
```

Exceptions

Undefined Instruction, Hyp Trap.

A8.8.286 VAND (immediate)

This is a pseudo-instruction, equivalent to a VBIC (immediate) instruction with the immediate value bitwise inverted. For details see *VBIC (immediate)* on page A8-838.

A8.8.287 VAND (register)

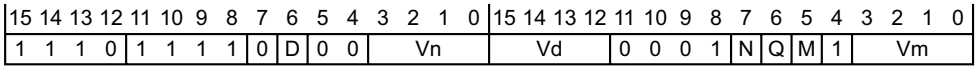
This instruction performs a bitwise AND operation between two registers, and places the result in the destination register.

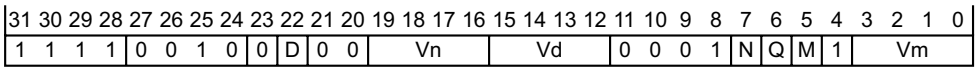
Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page B1-1232 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see *Conditional execution* on page A8-288.

Encoding T1/A1 Advanced SIMD

```
VAND<c> <Qd>, <Qn>, <Qm>
VAND<c> <Dd>, <Dn>, <Dm>
```





```
if Q == '1' && (Vd<0> == '1' || Vn<0> == '1' || Vm<0> == '1') then UNDEFINED;
d = UInt(D:Vd);  n = UInt(N:Vn);  m = UInt(M:Vm);  regs = if Q == '0' then 1 else 2;
```

Assembler syntax

`VAND{<c>}{<q>}{.<dt>}  {<Qd>,} <Qn>, <Qm>`	Encoded as Q = 1
`VAND{<c>}{<q>}{.<dt>}  {<Dd>,} <Dn>, <Dm>`	Encoded as Q = 0

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287. An ARM `VAND` instruction must be unconditional. ARM strongly recommends that a Thumb `VAND` instruction is unconditional, see *Conditional execution* on page A8-288.

`<dt>` An optional data type. It is ignored by assemblers, and does not affect the encoding.

`<Qd>, <Qn>, <Qm>` The destination vector and the operand vectors, for a quadword operation.

`<Dd>, <Dn>, <Dm>` The destination vector and the operand vectors, for a doubleword operation.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        D[d+r] = D[n+r] AND D[m+r];
```

Exceptions

Undefined Instruction, Hyp Trap.

A8.8.288 VBIC (immediate)

Vector Bitwise Bit Clear (immediate) performs a bitwise AND between a register value and the complement of an immediate value, and returns the result into the destination vector. For the range of constants available, see *One register and a modified immediate value* on page A7-269.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page B1-1232 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see *Conditional execution* on page A8-288.

Encoding T1/A1 Advanced SIMD

```
VBIC<c>.<dt> <Qd>, #<imm>
VBIC<c>.<dt> <Dd>, #<imm>
```

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	i	1	1	1	1	1	D	0	0	0	imm3			Vd				cmode				0	Q	1	1	imm4			

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	0	0	1	i	1	D	0	0	0	imm3			Vd				cmode				0	Q	1	1	imm4			

```
if cmode<0> == '0' || cmode<3:2> == '11' then SEE "Related encodings";
if Q == '1' && Vd<0> == '1' then UNDEFINED;
imm64 = AdvSIMDExpandImm('1', cmode, i:imm3:imm4);
d = UInt(D:Vd);  regs = if Q == '0' then 1 else 2;
```

Related encodings See *One register and a modified immediate value* on page A7-269.

Assembler syntax

`VBIC{<c>}{<q>}.<dt>  {<Qd>,} <Qd>, #<imm>`	Encoded as Q = 1
`VBIC{<c>}{<q>}.<dt>  {<Dd>,} <Dd>, #<imm>>`	Encoded as Q = 0

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287. An ARM `VBIC` instruction must be unconditional. ARM strongly recommends that a Thumb `VBIC` instruction is unconditional, see *Conditional execution* on page A8-288.

`<dt>` The data type used for `<imm>`. It can be either `I16` or `I32`.

`I8`, `I64`, and `F32` are also permitted, but the resulting syntax is a pseudo-instruction.

`<Qd>` The destination vector for a quadword operation.

`<Dd>` The destination vector for a doubleword operation.

`<imm>` A constant of the type specified by `<dt>`. This constant is replicated enough times to fill the destination register. For example, `VBIC.I32 D0, #10` ANDs the complement of `0x0000000A0000000A` with D0, and puts the result into D0.

For details of the range of constants available and the encoding of `<dt>` and `<imm>`, see *One register and a modified immediate value* on page A7-269.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        D[d+r] = D[d+r] AND NOT(imm64);
```

Exceptions

Undefined Instruction, Hyp Trap.

Pseudo-instructions

`VAND` can be used with a range of constants that are the bitwise inverse of the available constants for `VBIC`. This is assembled as the equivalent `VBIC` instruction. Disassembly produces the `VBIC` form.

One register and a modified immediate value on page A7-269 describes pseudo-instructions with a combination of `<dt>` and `<imm>` that is not supported by hardware, but that generates the same destination register value as a different combination that is supported by hardware.

A8.8.289 VBIC (register)

Vector Bitwise Bit Clear (register) performs a bitwise AND between a register value and the complement of a register value, and places the result in the destination register.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page B1-1232 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see *Conditional execution* on page A8-288.

            when VBitOps_VBSL  D[d+r] = (D[n+r] AND D[d+r]) OR (D[m+r] AND NOT(D[d+r]);
```

Exceptions

Undefined Instruction, Hyp Trap.

A8.8.291 VCEQ (register)

VCEQ (Vector Compare Equal) takes each element in a vector, and compares it with the corresponding element of a second vector. If they are equal, the corresponding element in the destination vector is set to all ones. Otherwise, it is set to all zeros.

The operand vector elements can be any one of:

- 8-bit, 16-bit, or 32-bit integers. There is no distinction between signed and unsigned integers.
- 32-bit floating-point numbers.

The result vector elements are fields the same size as the operand vector elements.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page B1-1232 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see *Conditional execution* on page A8-288.

A8.8.292 VCEQ (immediate #0)

VCEQ #0 (Vector Compare Equal to zero) takes each element in a vector, and compares it with zero. If it is equal to zero, the corresponding element in the destination vector is set to all ones. Otherwise, it is set to all zeros.

The operand vector elements can be any one of:

- 8-bit, 16-bit, or 32-bit integers. There is no distinction between signed and unsigned integers.
- 32-bit floating-point numbers.

The result vector elements are fields the same size as the operand vector elements.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page B1-1232 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see *Conditional execution* on page A8-288.

if Q == '1' && (Vd<0> == '1' || Vm<0> == '1') then UNDEFINED;
floating_point = (F == '1');
esize = 8 << UInt(size);  elements = 64 DIV esize;
d = UInt(D:Vd);  m = UInt(M:Vm);  regs = if Q == '0' then 1 else 2;
```

Assembler syntax

`VCLE{<c>}{<q>}.<dt>  {<Qd>,} <Qm>, #0`	Encoded as Q = 1
`VCLE{<c>}{<q>}.<dt>  {<Dd>,} <Dm>, #0`	Encoded as Q = 0

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287. An ARM `VCLE` instruction must be unconditional. ARM strongly recommends that a Thumb `VCLE` instruction is unconditional, see *Conditional execution* on page A8-288.

`<dt>` The data types for the elements of the operands. It must be one of:

- `S8` encoded as size = `0b00`, F = 0.
- `S16` encoded as size = `0b01`, F = 0.
- `S32` encoded as size = `0b10`, F = 0.
- `F32` encoded as size = `0b10`, F = 1.

`<Qd>, <Qm>` The destination vector and the operand vector, for a quadword operation.

`<Dd>, <Dm>` The destination vector and the operand vector, for a doubleword operation.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        for e = 0 to elements-1
            if floating_point then
                test_passed = FPCompareGE(FPZero('0',esize), Elem[D[m+r],e,esize], FALSE);
            else
                test_passed = (SInt(Elem[D[m+r],e,esize]) <= 0);
            Elem[D[d+r],e,esize] = if test_passed then Ones(esize) else Zeros(esize);
```

Exceptions

Undefined Instruction, Hyp Trap.

Floating-point exceptions

Input Denormal, Invalid Operation.

A8.8.299 VCLS

Vector Count Leading Sign Bits counts the number of consecutive bits following the topmost bit, that are the same as the topmost bit, in each element in a vector, and places the results in a second vector. The count does not include the topmost bit itself.

The operand vector elements can be any one of 8-bit, 16-bit, or 32-bit signed integers.

The result vector elements are the same data type as the operand vector elements.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page B1-1232 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see *Conditional execution* on page A8-288.

            Elem[D[d+r],e,esize] = CountLeadingSignBits(Elem[D[m+r],e,esize]);
```

Exceptions

Undefined Instruction, Hyp Trap.

A8.8.300 VCLT (register)

VCLT is a pseudo-instruction, equivalent to a VCGT instruction with the operands reversed. For details see *VCGT (register)* on page A8-852.

A8.8.301 VCLT (immediate #0)

VCLT #0 (Vector Compare Less Than Zero) take each element in a vector, and compares it with zero. If it is less than zero, the corresponding element in the destination vector is set to all ones. Otherwise, it is set to all zeros.

The operand vector elements can be any one of:

- 8-bit, 16-bit, or 32-bit signed integers
- 32-bit floating-point numbers.

The result vector elements are fields the same size as the operand vector elements.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page B1-1232 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see *Conditional execution* on page A8-288.

Encoding T1/A1 Advanced SIMD (F = 1 UNDEFINED in integer-only variants)

```

Exceptions

Undefined Instruction, Hyp Trap.

A8.8.303 VCMP, VCMPE

This instruction compares two floating-point registers, or one floating-point register and zero. It writes the result to the FPSCR flags. These are normally transferred to the ARM flags by a subsequent VMRS instruction.

It can optionally raise an Invalid Operation exception if either operand is any type of NaN. It always raises an Invalid Operation exception if either operand is a signaling NaN.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of general controls of CP10 and CP11 functionality* on page B1-1230 summarizes these controls.

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckVFPEnabled(TRUE);
    if dp_operation then
        op2 = if with_zero then FPZero('0',64) else D[m];
        (FPSCR.N, FPSCR.Z, FPSCR.C, FPSCR.V) = FPCompare(D[d], op2, quiet_nan_exc, TRUE);
    else
        op2 = if with_zero then FPZero('0',32) else S[m];
        (FPSCR.N, FPSCR.Z, FPSCR.C, FPSCR.V) = FPCompare(S[d], op2, quiet_nan_exc, TRUE);
```

Exceptions

Undefined Instruction, Hyp Trap.

Floating-point exceptions

Invalid Operation, Input Denormal.

NaNs

The IEEE 754 standard specifies that the result of a comparison is precisely one of <, ==, > or *unordered*. If either or both of the operands are NaNs, they are unordered, and all three of (Operand1 < Operand2), (Operand1 == Operand2) and (Operand1 > Operand2) are false. This results in the FPSCR flags being set as N=0, Z=0, C=1 and V=1.

`VCMPE` raises an Invalid Operation exception if either operand is any type of NaN, and is suitable for testing for <, <=, >, >=, and other predicates that raise an exception when the operands are unordered.

A8.8.304 VCNT

This instruction counts the number of bits that are one in each element in a vector, and places the results in a second vector.

The operand vector elements must be 8-bit fields.

The result vector elements are 8-bit integers.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page B1-1232 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see *Conditional execution* on page A8-288.

```

Exceptions

Undefined Instruction, Hyp Trap.

A8.8.305 VCVT (between floating-point and integer, Advanced SIMD)

This instruction converts each element in a vector from floating-point to integer, or from integer to floating-point, and places the results in a second vector.

The vector elements must be 32-bit floating-point numbers, or 32-bit integers. Signed and unsigned integers are distinct.

The floating-point to integer operation uses the Round towards Zero rounding mode. The integer to floating-point operation uses the Round to Nearest rounding mode.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page B1-1232 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see *Conditional execution* on page A8-288.

            Elem[D[d+r],e,esize] = result;
```

Exceptions

Undefined Instruction, Hyp Trap.

Floating-point exceptions

Input Denormal, Invalid Operation, Inexact.

A8.8.306 VCVT, VCVTR (between floating-point and integer, Floating-point)

These instructions convert a value in a register from floating-point to a 32-bit integer, or from a 32-bit integer to floating-point, and place the result in a second register.

The floating-point to integer operation normally uses the Round towards Zero rounding mode, but can optionally use the rounding mode specified by the FPSCR. The integer to floating-point operation uses the rounding mode specified by the FPSCR.

VCVT (between floating-point and fixed-point, Floating-point) on page A8-874 describes conversions between floating-point and 16-bit integers.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of general controls of CP10 and CP11 functionality* on page B1-1230 summarizes these controls.

        else
            S[d] = FixedToFP(S[m], 32, 0, unsigned, round_nearest, TRUE);
```

Exceptions

Undefined Instruction, Hyp Trap.

Floating-point exceptions

Input Denormal, Invalid Operation, Inexact.

A8.8.307 VCVT (between floating-point and fixed-point, Advanced SIMD)

This instruction converts each element in a vector from floating-point to fixed-point, or from fixed-point to floating-point, and places the results in a second vector.

The vector elements must be 32-bit floating-point numbers, or 32-bit integers. Signed and unsigned integers are distinct.

The floating-point to fixed-point operation uses the Round towards Zero rounding mode. The fixed-point to floating-point operation uses the Round to Nearest rounding mode.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page B1-1232 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see *Conditional execution* on page A8-288.

Encoding T1/A1 Advanced SIMD (UNDEFINED in integer-only variant)

                result = FixedToFP(op, esize, frac_bits, unsigned, round_nearest, FALSE);
            Elem[D[d+r],e,esize] = result;
```

Exceptions

Undefined Instruction, Hyp Trap.

Floating-point exceptions

Input Denormal, Invalid Operation, Inexact.

A8.8.308 VCVT (between floating-point and fixed-point, Floating-point)

This instruction converts a value in a register from floating-point to fixed-point, or from fixed-point to floating-point. Software can specify the fixed-point value as either signed or unsigned.

The floating-point value can be single-precision or double-precision.

The fixed-point value can be 16-bit or 32-bit. Conversions from fixed-point values take their operand from the low-order bits of the source register and ignore any remaining bits. Signed conversions to fixed-point values sign-extend the result value to the destination register width. Unsigned conversions to fixed-point values zero-extend the result value to the destination register width.

The floating-point to fixed-point operation uses the Round towards Zero rounding mode. The fixed-point to floating-point operation uses the Round to Nearest rounding mode.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of general controls of CP10 and CP11 functionality* on page B1-1230 summarizes these controls.

```

Assembler syntax

`VDUP{<c>}{<q>}.<size>  <Qd>, <Dm[x]>`	Encoded as Q = 1
`VDUP{<c>}{<q>}.<size>  <Dd>, <Dm[x]>`	Encoded as Q = 0

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287. An ARM `VDUP` instruction must be unconditional. ARM strongly recommends that a Thumb `VDUP` instruction is unconditional, see *Conditional execution* on page A8-288.

`<size>` The data size. It must be one of:

- `8` Encoded as imm4<0> = '1'. imm4<3:1> encodes the index `[x]` of the scalar.
- `16` Encoded as imm4<1:0> = '10'. imm4<3:2> encodes the index `[x]` of the scalar.
- `32` Encoded as imm4<2:0> = '100'. imm4<3> encodes the index `[x]` of the scalar.

`<Qd>` The destination vector for a quadword operation.

`<Dd>` The destination vector for a doubleword operation.

`<Dm[x]>` The scalar. For details of how `[x]` is encoded, see the description of `<size>`.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    scalar = Elem[D[m],index,esize];
    for r = 0 to regs-1
        for e = 0 to elements-1
            Elem[D[d+r],e,esize] = scalar;
```

Exceptions

Undefined Instruction, Hyp Trap.

A8.8.314 VDUP (ARM core register)

This instruction duplicates an element from an ARM core register into every element of the destination vector.

The destination vector elements can be 8-bit, 16-bit, or 32-bit fields. The source element is the least significant 8, 16, or 32 bits of the ARM core register. There is no distinction between data types.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page B1-1232 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see *Conditional execution* on page A8-288.

Assembler syntax

`VDUP{<c>}{<q>}.<size>  <Qd>, <Rt>`	Encoded as Q = 1
`VDUP{<c>}{<q>}.<size>  <Dd>, <Rt>`	Encoded as Q = 0

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287. ARM strongly recommends that any `VDUP` instruction is unconditional, see *Conditional execution* on page A8-288.

`<size>` The data size for the elements of the destination vector. It must be one of:

- `8` encoded as [b, e] = `0b10`.
- `16` encoded as [b, e] = `0b01`.
- `32` encoded as [b, e] = `0b00`.

`<Qd>` The destination vector for a quadword operation.

`<Dd>` The destination vector for a doubleword operation.

`<Rt>` The ARM source register.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    scalar = R[t]<esize-1:0>;
    for r = 0 to regs-1
        for e = 0 to elements-1
            Elem[D[d+r],e,esize] = scalar;
```

Exceptions

Undefined Instruction, Hyp Trap.

A8.8.315 VEOR

Vector Bitwise Exclusive OR performs a bitwise Exclusive OR operation between two registers, and places the result in the destination register. The operand and result registers can be quadword or doubleword. They must all be the same size.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page B1-1232 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see *Conditional execution* on page A8-288.

d = UInt(D:Vd);  n = UInt(N:Vn);  m = UInt(M:Vm);  regs = if Q == '0' then 1 else 2;
```

Assembler syntax

`VEOR{<c>}{<q>}{.<dt>}  {<Qd>,} <Qn>, <Qm>`	Encoded as Q = 1
`VEOR{<c>}{<q>}{.<dt>}  {<Dd>,} <Dn>, <Dm>`	Encoded as Q = 0

where:

`<c>, <q>`	See *Standard assembler syntax fields* on page A8-287. An ARM `VEOR` instruction must be unconditional. ARM strongly recommends that a Thumb `VEOR` instruction is unconditional, see *Conditional execution* on page A8-288.
`<dt>`	An optional data type. It is ignored by assemblers, and does not affect the encoding.
`<Qd>, <Qn>, <Qm>`	The destination vector and the operand vectors, for a quadword operation.
`<Dd>, <Dn>, <Dm>`	The destination vector and the operand vectors, for a doubleword operation.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        D[d+r] = D[n+r] EOR D[m+r];
```

Exceptions

Undefined Instruction, Hyp Trap.

A8.8.316 VEXT

Vector Extract extracts elements from the bottom end of the second operand vector and the top end of the first, concatenates them and places the result in the destination vector. See Figure A8-1 for an example.

The elements of the vectors are treated as being 8-bit fields. There is no distinction between data types.

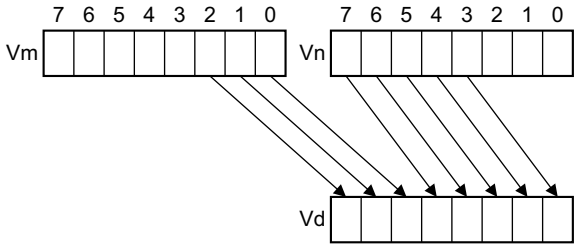

Figure A8-1 VEXT doubleword operation for imm = 3

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page B1-1232 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see *Conditional execution* on page A8-288.

Encoding T1/A1 Advanced SIMD

```
VEXT<c>.8 <Qd>, <Qn>, <Qm>, #<imm>
VEXT<c>.8 <Dd>, <Dn>, <Dm>, #<imm>
```

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	0	0	1	0	1	D	1	1	Vn				Vd				imm4				N	Q	M	0	Vm			

```
if Q == '1' && (Vd<0> == '1' || Vn<0> == '1' || Vm<0> == '1') then UNDEFINED;
if Q == '0' && imm4<3> == '1' then UNDEFINED;
quadword_operation = (Q == '1');  position = 8 * UInt(imm4);
d = UInt(D:Vd);  n = UInt(N:Vn);  m = UInt(M:Vm);
```

Assembler syntax

`VEXT{<c>}{<q>}.<size>  {<Qd>,} <Qn>, <Qm>, #<imm>`	Encoded as Q = 1
`VEXT{<c>}{<q>}.<size>  {<Dd>,} <Dn>, <Dm>, #<imm>`	Encoded as Q = 0

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287. An ARM `VEXT` instruction must be unconditional. ARM strongly recommends that a Thumb `VEXT` instruction is unconditional, see *Conditional execution* on page A8-288.

`<size>` Size of the operation. The value can be:

- 8, 16, or 32 for doubleword operations
- 8, 16, 32, or 64 for quadword operations.

If the value is 16, 32, or 64, the syntax is a pseudo-instruction for a `VEXT` instruction specifying the equivalent number of bytes. The following examples show how an assembler treats values greater than 8:

`VEXT.16 D0, D1, #x` is treated as `VEXT.8 D0, D1, #(x*2)`

`VEXT.32 D0, D1, #x` is treated as `VEXT.8 D0, D1, #(x*4)`

`VEXT.64 Q0, Q1, #x` is treated as `VEXT.8 Q0, Q1, #(x*8)`.

`<Qd>, <Qn>, <Qm>` The destination vector and the operand vectors, for a quadword operation.

`<Dd>, <Dn>, <Dm>` The destination vector and the operand vectors, for a doubleword operation.

`<imm>` The location of the extracted result in the concatenation of the operands, as a number of bytes from the least significant end, in the range 0-7 for a doubleword operation or 0-15 for a quadword operation.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    if quadword_operation then
        Q[d>>1] = (Q[m>>1]:Q[n>>1])<position+127:position>;
    else
        D[d] = (D[m]:D[n])<position+63:position>;
```

Exceptions

Undefined Instruction, Hyp Trap.

A8.8.317 VFMA, VFMS

Vector Fused Multiply Accumulate multiplies corresponding elements of two vectors, and accumulates the results into the elements of the destination vector. The instruction does not round the result of the multiply before the accumulation.

Vector Fused Multiply Subtract negates the elements of one vector and multiplies them with the corresponding elements of another vector, adds the products to the corresponding elements of the destination vector, and places the results in the destination vector. The instruction does not round the result of the multiply before the addition.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of general controls of CP10 and CP11 functionality* on page B1-1230 and *Summary of access controls for Advanced SIMD functionality* on page B1-1232 summarize these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see *Conditional execution* on page A8-288.

The operation (QNaN + (0 × infinity)) causes an Invalid Operation floating-point exception.

A8.8.319 VHADD, VHSUB

Vector Halving Add adds corresponding elements in two vectors of integers, shifts each result right one bit, and places the final results in the destination vector. The results of the halving operations are truncated (for rounded results see *VRHADD* on page A8-1030).

Vector Halving Subtract subtracts the elements of the second operand from the corresponding elements of the first operand, shifts each result right one bit, and places the final results in the destination vector. The results of the halving operations are truncated (there is no rounding version).

The operand and result elements are all the same type, and can be any one of:

- 8-bit, 16-bit, or 32-bit signed integers
- 8-bit, 16-bit, or 32-bit unsigned integers.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page B1-1232 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see *Conditional execution* on page A8-288.

- `U32` encoded as size = `0b10`, U = 1.

`<Qd>, <Qn>, <Qm>` The destination vector and the operand vectors, for a quadword operation.

`<Dd>, <Dn>, <Dm>` The destination vector and the operand vectors, for a doubleword operation.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        for e = 0 to elements-1
            op1 = Int(Elem[D[n+r],e,esize], unsigned);
            op2 = Int(Elem[D[m+r],e,esize], unsigned);
            result = if add then op1+op2 else op1-op2;
            Elem[D[d+r],e,esize] = result<esize:1>;
```

Exceptions

Undefined Instruction, Hyp Trap.

A8.8.320 VLD1 (multiple single elements)

This instruction loads elements from memory into one, two, three, or four registers, without de-interleaving. Every element of each register is loaded. For details of the addressing mode see *Advanced SIMD addressing mode* on page A7-277.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page B1-1232 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see *Conditional execution* on page A8-288.

Assembler syntax

`VLD1{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]`	Encoded as Rm = `0b1111`
`VLD1{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]!`	Encoded as Rm = `0b1101`
`VLD1{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}], <Rm>`	Rm cannot be `0b11x1`

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287. An ARM `VLD1` instruction must be unconditional. ARM strongly recommends that a Thumb `VLD1` instruction is unconditional, see *Conditional execution* on page A8-288.

`<size>` The data size. It must be one of:

- `8` encoded as size = `0b00`.
- `16` encoded as size = `0b01`.
- `32` encoded as size = `0b10`.
- `64` encoded as size = `0b11`.

`<list>` The list of registers to load. It must be one of:

`{<Dd>}`	encoded as D:Vd = `<Dd>`, type = `0b0111`.
`{<Dd>, <Dd+1>}`	encoded as D:Vd = `<Dd>`, type = `0b1010`.
`{<Dd>, <Dd+1>, <Dd+2>}`	encoded as D:Vd = `<Dd>`, type = `0b0110`.
`{<Dd>, <Dd+1>, <Dd+2>, <Dd+3>}`	encoded as D:Vd = `<Dd>`, type = `0b0010`.

`<Rn>` Contains the base address for the access.

`<align>` The alignment. It can be one of:

`64`	8-byte alignment, encoded as align = `0b01`.
`128`	16-byte alignment, available only if `<list>` contains two or four registers, encoded as align = `0b10`.
`256`	32-byte alignment, available only if `<list>` contains four registers, encoded as align = `0b11`.
omitted	Standard alignment, see *Unaligned data access* on page A3-108. Encoded as align = `0b00`.

: is the preferred separator before the `<align>` value, but the alignment can be specified as `@<align>`, see *Advanced SIMD addressing mode* on page A7-277.

`!` If present, specifies writeback.

`<Rm>` Contains an address offset applied after the access.

For more information about `<Rn>`, `!`, and `<Rm>`, see *Advanced SIMD addressing mode* on page A7-277.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();  NullCheckIfThumbEE(n);
    address = R[n];  if (address MOD alignment) != 0 then GenerateAlignmentException();
    if wback then R[n] = R[n] + (if register_index then R[m] else 8*regs);
    for r = 0 to regs-1
        for e = 0 to elements-1
            if ebytes != 8 then
                data<esize-1:0> = MemU[address,ebytes];
            else
                data<31:0> = if BigEndian() then MemU[address+4,4] else MemU[address,4];
                data<63:32> = if BigEndian() then MemU[address,4] else MemU[address+4,4];
            Elem[D[d+r],e,esize] = data<esize-1:0>;
            address = address + ebytes;
```

Exceptions

Undefined Instruction, Hyp Trap, Data Abort.

A8.8.321 VLD1 (single element to one lane)

This instruction loads one element from memory into one element of a register. Elements of the register that are not loaded are unchanged. For details of the addressing mode see *Advanced SIMD addressing mode* on page A7-277.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page B1-1232 summarizes these controls.

- `16` encoded as size = `0b01`.
- `32` encoded as size = `0b10`.

<list> The registers containing the structure. Encoded with D:Vd = <Dd>. It must be one of:

{<Dd[x]>, <Dd+1[x]>} Single-spaced registers, see Table A8-5.

{<Dd[x]>, <Dd+2[x]>} Double-spaced registers, see Table A8-5. This is not available if <size> == 8.

<Rn> Contains the base address for the access.

<align> The alignment. It can be one of:

16 2-byte alignment, available only if <size> is 8

32 4-byte alignment, available only if <size> is 16

64 8-byte alignment, available only if <size> is 32

omitted Standard alignment, see *Unaligned data access* on page A3-108.

: is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see *Advanced SIMD addressing mode* on page A7-277.

! If present, specifies writeback.

<Rm> Contains an address offset applied after the access.

For more information about <Rn>, !, and <Rm> see *Advanced SIMD addressing mode* on page A7-277.

Table A8-5 Encoding of index, alignment, and register spacing

	<size> == 8	<size> == 16	<size> == 32
Index	index_align[3:1] = x	index_align[3:2] = x	index_align[3] = x
Single-spacing	-	index_align[1] = 0	index_align[2] = 0
Double-spacing	-	index_align[1] = 1	index_align[2] = 1
<align> omitted	index_align[0] = 0	index_align[0] = 0	index_align[1:0] = '00'
<align> == 16	index_align[0] = 1	-	-
<align> == 32	-	index_align[0] = 1	-
<align> == 64	-	-	index_align[1:0] = '01'

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();  NullCheckIfThumbEE(n);
    address = R[n];  if (address MOD alignment) != 0 then GenerateAlignmentException();
    if wback then R[n] = R[n] + (if register_index then R[m] else 2*ebytes);
    Elem[D[d],index,esize] = MemU[address,ebytes];
    Elem[D[d2],index,esize] = MemU[address+ebytes,ebytes];
```

Exceptions

Undefined Instruction, Hyp Trap, Data Abort.

A8.8.325 VLD2 (single 2-element structure to all lanes)

This instruction loads one 2-element structure from memory into all lanes of two registers. For details of the addressing mode see *Advanced SIMD addressing mode* on page A7-277.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page B1-1232 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see *Conditional execution* on page A8-288.

Encoding T1/A1 Advanced SIMD

if n == 15 || d2 > 31 then UNPREDICTABLE;
```

Assembler syntax

`VLD2{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]`	Encoded as Rm = `0b1111`
`VLD2{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]!`	Encoded as Rm = `0b1101`
`VLD2{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}], <Rm>`	Rm cannot be `0b11x1`

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287. An ARM `VLD2` instruction must be unconditional. ARM strongly recommends that a Thumb `VLD2` instruction is unconditional, see *Conditional execution* on page A8-288.

`<size>` The data size. It must be one of:

- `8` encoded as size = `0b00`.
- `16` encoded as size = `0b01`.
- `32` encoded as size = `0b10`.

`<list>` The registers containing the structure. It must be one of:

- `{<Dd[]>, <Dd+1[]>}` Single-spaced registers, encoded as D:Vd = `<Dd>`, T = 0.
- `{<Dd[]>, <Dd+2[]>}` Double-spaced registers, encoded as D:Vd = `<Dd>`, T = 1.

`<Rn>` Contains the base address for the access.

`<align>` The alignment. It can be one of:

- `16` 2-byte alignment, available only if `<size>` is 8, encoded as a = 1.
- `32` 4-byte alignment, available only if `<size>` is 16, encoded as a = 1.
- `64` 8-byte alignment, available only if `<size>` is 32, encoded as a = 1.
- **omitted** Standard alignment, see *Unaligned data access* on page A3-108. Encoded as a = 0.

: is the preferred separator before the `<align>` value, but the alignment can be specified as `@<align>`, see *Advanced SIMD addressing mode* on page A7-277.

`!` If present, specifies writeback.

`<Rm>` Contains an address offset applied after the access.

For more information about `<Rn>`, `!`, and `<Rm>`, see *Advanced SIMD addressing mode* on page A7-277.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();  NullCheckIfThumbEE(n);
    address = R[n];  if (address MOD alignment) != 0 then GenerateAlignmentException();
    if wback then R[n] = R[n] + (if register_index then R[m] else 2*ebytes);
    D[d] = Replicate(MemU[address,ebytes], elements);
    D[d2] = Replicate(MemU[address+ebytes,ebytes], elements);
```

Exceptions

Undefined Instruction, Hyp Trap, Data Abort.

A8.8.326 VLD3 (multiple 3-element structures)

This instruction loads multiple 3-element structures from memory into three registers, with de-interleaving. For more information, see *Element and structure load/store instructions* on page A4-181. Every element of each register is loaded. For details of the addressing mode see *Advanced SIMD addressing mode* on page A7-277.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page B1-1232 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see *Conditional execution* on page A8-288.

        address = address + 4*ebytes;
```

Exceptions

Undefined Instruction, Hyp Trap, Data Abort.

A8.8.330 VLD4 (single 4-element structure to one lane)

This instruction loads one 4-element structure from memory into corresponding elements of four registers. Elements of the registers that are not loaded are unchanged. For details of the addressing mode see *Advanced SIMD addressing mode* on page A7-277.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page B1-1232 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see *Conditional execution* on page A8-288.

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287. An ARM `VLD4` instruction must be unconditional. ARM strongly recommends that a Thumb `VLD4` instruction is unconditional, see *Conditional execution* on page A8-288.

`<size>` The data size. It must be one of:

- `8` encoded as size = `0b00`.
- `16` encoded as size = `0b01`.
- `32` encoded as size = `0b10`.

<list> The registers containing the structure. Encoded with D:Vd = <Dd>. It must be one of:

{<Dd[x]>, <Dd+1[x]>, <Dd+2[x]>, <Dd+3[x]>}
Single-spaced registers, see Table A8-7.

{<Dd[x]>, <Dd+2[x]>, <Dd+4[x]>, <Dd+6[x]>}
Double-spaced registers, see Table A8-7.
Not available if <size> == 8.

<Rn> The base address for the access.

<align> The alignment. It can be:

32 4-byte alignment, available only if <size> is 8.

64 8-byte alignment, available only if <size> is 16 or 32.

128 16-byte alignment, available only if <size> is 32.

omitted Standard alignment, see *Unaligned data access* on page A3-108.

: is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see *Advanced SIMD addressing mode* on page A7-277.

! If present, specifies writeback.

<Rm> Contains an address offset applied after the access.

For more information about <Rn>, !, and <Rm> see *Advanced SIMD addressing mode* on page A7-277.

Table A8-7 Encoding of index, alignment, and register spacing

	<size> == 8	<size> == 16	<size> == 32
Index	index_align[3:1] = x	index_align[3:2] = x	index_align[3] = x
Single-spacing	-	index_align[1] = 0	index_align[2] = 0

if n == 15 && (wback || CurrentInstrSet() != InstrSet_ARM) then UNPREDICTABLE;
if regs == 0 || (d+regs) > 32 then UNPREDICTABLE;
```

Related encodings See *64-bit transfers between ARM core and extension registers* on page A7-279.

FLDMX Encoding T1/A1 behaves as described by the pseudocode if imm8 is odd. However, there is no UAL syntax for such encodings and ARM deprecates their use. For more information, see *FLDMX, FSTMX* on page A8-388.

Assembler syntax

```
VLDM{<mode>}{<c>}{<q>}{.<size>}  <Rn>{!}, <list>
```

where:

`<mode>` The addressing mode:

- `IA` Increment After. The consecutive addresses start at the address specified in `<Rn>`. This is the default and can be omitted. Encoded as P = 0, U = 1.
- `DB` Decrement Before. The consecutive addresses end just before the address specified in `<Rn>`. Encoded as P = 1, U = 0.

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287.

`<size>` An optional data size specifier. If present, it must be equal to the size in bits, 32 or 64, of the registers in `<list>`.

`<Rn>` The base register. The SP can be used. In the ARM instruction set, if `!` is not specified the PC can be used.

`!` Causes the instruction to write a modified value back to `<Rn>`. This is required if `<mode>` == `DB`, and is optional if `<mode>` == `IA`. Encoded as W = 1.

If `!` is omitted, the instruction does not change `<Rn>` in this way. Encoded as W = 0.

`<list>` The extension registers to be loaded, as a list of consecutively numbered doubleword (encoding T1/A1) or singleword (encoding T2/A2) registers, separated by commas and surrounded by brackets. It is encoded in the instruction by setting D and Vd to specify the first register in the list, and imm8 to twice the number of registers in the list (encoding T1/A1) or the number of registers in the list (encoding T2/A2). `<list>` must contain at least one register. If it contains doubleword registers it must not contain more than 16 registers.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckVFPEnabled(TRUE);  NullCheckIfThumbEE(n);
    address = if add then R[n] else R[n]-imm32;
    if wback then R[n] = if add then R[n]+imm32 else R[n]-imm32;
    for r = 0 to regs-1
        if single_regs then
            S[d+r] = MemA[address,4];  address = address+4;
        else
            word1 = MemA[address,4];  word2 = MemA[address+4,4];  address = address+8;
            // Combine the word-aligned words in the correct order for current endianness.
            D[d+r] = if BigEndian() then word1:word2 else word2:word1;
```

Exceptions

Undefined Instruction, Hyp Trap, Data Abort.

A8.8.333 VLDR

This instruction loads a single extension register from memory, using an address from an ARM core register, with an optional offset.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of general controls of CP10 and CP11 functionality* on page B1-1230 and *Summary of access controls for Advanced SIMD functionality* on page B1-1232 summarize these controls.

Assembler syntax

`VLDR{<c>}{<q>}{.64}  <Dd>, [<Rn> {, #+/-<imm>}]`	Encoding T1/A1, immediate form
`VLDR{<c>}{<q>}{.64}  <Dd>, <label>`	Encoding T1/A1, normal literal form
`VLDR{<c>}{<q>}{.64}  <Dd>, [PC, #+/-<imm>]`	Encoding T1/A1, alternative literal form
`VLDR{<c>}{<q>}{.32}  <Sd>, [<Rn> {, #+/-<imm>}]`	Encoding T2/A2, immediate form
`VLDR{<c>}{<q>}{.32}  <Sd>, <label>`	Encoding T2/A2, normal literal form
`VLDR{<c>}{<q>}{.32}  <Sd>, [PC, #+/-<imm>]`	Encoding T2/A2, alternative literal form

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287.

`.32, .64` Optional data size specifiers.

`<Dd>` The destination register for a doubleword load.

`<Sd>` The destination register for a singleword load.

`<Rn>` The base register. The SP can be used.

`+/-` Is + or omitted if the immediate offset is to be added to the base register value (`add == TRUE`), or – if it is to be subtracted (`add == FALSE`). `#0` and `#-0` generate different instructions.

`<imm>` The immediate offset used for forming the address. For the immediate forms of the syntax, `<imm>` can be omitted, in which case the #0 form of the instruction is assembled. Permitted values are multiples of 4 in the range 0 to 1020.

`<label>` The label of the literal data item to be loaded. The assembler calculates the required value of the offset from the `Align(PC, 4)` value of the instruction to this label. Permitted values are multiples of 4 in the range -1020 to 1020.

If the offset is zero or positive, `imm32` is equal to the offset and `add == TRUE`.

If the offset is negative, `imm32` is equal to minus the offset and `add == FALSE`.

For the literal forms of the instruction, the base register is encoded as `0b1111` to indicate that the PC is the base register.

The alternative syntax permits the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see *Use of labels in UAL instruction syntax* on page A4-162.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckVFPEnabled(TRUE);  NullCheckIfThumbEE(n);
    base = if n == 15 then Align(PC,4) else R[n];
    address = if add then (base + imm32) else (base - imm32);
    if single_reg then
        S[d] = MemA[address,4];
    else
        word1 = MemA[address,4];  word2 = MemA[address+4,4];
        // Combine the word-aligned words in the correct order for current endianness.
        D[d] = if BigEndian() then word1:word2 else word2:word1;
```

Exceptions

Undefined Instruction, Hyp Trap, Data Abort.

A8.8.334 VMAX, VMIN (integer)

Vector Maximum compares corresponding elements in two vectors, and copies the larger of each pair into the corresponding element in the destination vector.

Vector Minimum compares corresponding elements in two vectors, and copies the smaller of each pair into the corresponding element in the destination vector.

The operand vector elements can be any one of:

- 8-bit, 16-bit, or 32-bit signed integers
- 8-bit, 16-bit, or 32-bit unsigned integers.

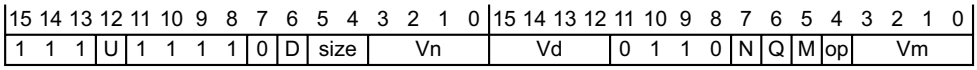
The result vector elements are the same size as the operand vector elements.

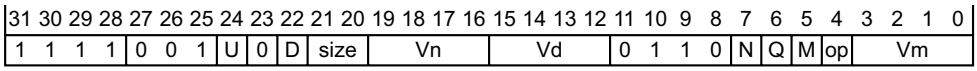
Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page B1-1232 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see *Conditional execution* on page A8-288.

Encoding T1/A1 Advanced SIMD

```
V<op><c>.<dt> <Qd>, <Qn>, <Qm>
V<op><c>.<dt> <Dd>, <Dn>, <Dm>
```





```
if Q == '1' && (Vd<0> == '1' || Vn<0> == '1' || Vm<0> == '1') then UNDEFINED;
if size == '11' then UNDEFINED;
maximum = (op == '0');  unsigned = (U == '1');
esize = 8 << UInt(size);  elements = 64 DIV esize;
d = UInt(D:Vd);  n = UInt(N:Vn);  m = UInt(M:Vm);  regs = if Q == '0' then 1 else 2;
```

Assembler syntax

`V<op>{<c>}{<q>}.<dt>  {<Qd>,} <Qn>, <Qm>`	Encoded as Q = 1
`V<op>{<c>}{<q>}.<dt>  {<Dd>,} <Dn>, <Dm>`	Encoded as Q = 0

where:

`<op>` The operation. It must be one of:

- `MAX` encoded as op = 0.
- `MIN` encoded as op = 1.

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287. An ARM `VMAX` or `VMIN` instruction must be unconditional. ARM strongly recommends that a Thumb `VMAX` or `VMIN` instruction is unconditional, see *Conditional execution* on page A8-288.

`<dt>` The data types for the elements of the vectors. It must be one of:

- `S8` encoded as size = `0b00`, U = 0.
- `S16` encoded as size = `0b01`, U = 0.
- `S32` encoded as size = `0b10`, U = 0.
- `U8` encoded as size = `0b00`, U = 1.
- `U16` encoded as size = `0b01`, U = 1.
- `U32` encoded as size = `0b10`, U = 1.

`<Qd>, <Qn>, <Qm>` The destination vector and the operand vectors, for a quadword operation.

`<Dd>, <Dn>, <Dm>` The destination vector and the operand vectors, for a doubleword operation.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        for e = 0 to elements-1
            op1 = Int(Elem[D[n+r],e,esize], unsigned);
            op2 = Int(Elem[D[m+r],e,esize], unsigned);
            result = if maximum then Max(op1,op2) else Min(op1,op2);
            Elem[D[d+r],e,esize] = result<esize-1:0>;
```

Exceptions

Undefined Instruction, Hyp Trap.

A8.8.335 VMAX, VMIN (floating-point)

Vector Maximum compares corresponding elements in two vectors, and copies the larger of each pair into the corresponding element in the destination vector.

Vector Minimum compares corresponding elements in two vectors, and copies the smaller of each pair into the corresponding element in the destination vector.

The operand vector elements are 32-bit floating-point numbers.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page B1-1232 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see *Conditional execution* on page A8-288.

                Elem[D[d+r],e,esize] = Elem[Din[d+r],e,esize] + addend;
```

Exceptions

Undefined Instruction, Hyp Trap.

A8.8.337 VMLA, VMLS (floating-point)

Vector Multiply Accumulate multiplies corresponding elements in two vectors, and accumulates the results into the elements of the destination vector.

Vector Multiply Subtract multiplies corresponding elements in two vectors, subtracts the products from corresponding elements of the destination vector, and places the results in the destination vector.

Note

ARM recommends that software does not use the `VMLS` instruction in the *Round towards Plus Infinity* and *Round towards Minus Infinity* rounding modes, because the rounding of the product and of the sum can change the result of the instruction in opposite directions, defeating the purpose of these rounding modes.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of general controls of CP10 and CP11 functionality* on page B1-1230 and *Summary of access controls for Advanced SIMD functionality* on page B1-1232 summarize these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see *Conditional execution* on page A8-288.

```

Exceptions

Undefined Instruction, Hyp Trap.

Floating-point exceptions

Input Denormal, Invalid Operation, Overflow, Underflow, Inexact.

A8.8.339 VMOV (immediate)

This instruction places an immediate constant into every element of the destination register.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of general controls of CP10 and CP11 functionality* on page B1-1230 and *Summary of access controls for Advanced SIMD functionality* on page B1-1232 summarize these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see *Conditional execution* on page A8-288.

Related encodings See *One register and a modified immediate value* on page A7-269.

VFP vectors Encoding T2/A2 can operate on VFP vectors under control of the FPSCR.{Len, Stride} fields. For details see Appendix K *VFP Vector Operation Support*.

Assembler syntax

`VMOV{<c>}{<q>}.<dt>  <Qd>, #<imm>`	Encoding T1/A1, encoded as Q = 1
`VMOV{<c>}{<q>}.<dt>  <Dd>, #<imm>`	Encoding T1/A1, encoded as Q = 0
`VMOV{<c>}{<q>}.F64  <Dd>, #<imm>`	Encoding T2/A2, encoded as sz = 1
`VMOV{<c>}{<q>}.F32  <Sd>, #<imm>`	Encoding T2/A2, encoded as sz = 0

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287. An ARM Advanced SIMD `VMOV` (immediate) instruction must be unconditional. ARM strongly recommends that a Thumb Advanced SIMD `VMOV` (immediate) instruction is unconditional, see *Conditional execution* on page A8-288.

`<dt>` The data type. It must be one of `I8`, `I16`, `I32`, `I64`, or `F32`.

`<Qd>` The destination register for a quadword operation.

`<Dd>` The destination register for a doubleword operation.

`<Sd>` The destination register for a singleword operation.

`<imm>` A constant of the type specified by `<dt>`. This constant is replicated enough times to fill the destination register. For example, `VMOV.I32 D0, #10` writes `0x0000000A0000000A` to D0.

For the range of constants available, and the encoding of `<dt>` and `<imm>`, see:

- *One register and a modified immediate value* on page A7-269 for encoding T1/A1
- *Floating-point data-processing instructions* on page A7-272 for encoding T2/A2.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDOrVFPEnabled(TRUE, advsimd);
    if single_register then
        S[d] = imm32;
    else
        for r = 0 to regs-1
            D[d+r] = imm64;
```

Exceptions

Undefined Instruction, Hyp Trap.

Pseudo-instructions

One register and a modified immediate value on page A7-269 describes pseudo-instructions with a combination of `<dt>` and `<imm>` that is not supported by hardware, but that generates the same destination register value as a different combination that is supported by hardware.

A8.8.340 VMOV (register)

This instruction copies the contents of one register to another.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of general controls of CP10 and CP11 functionality* on page B1-1230 and *Summary of access controls for Advanced SIMD functionality* on page B1-1232 summarize these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see *Conditional execution* on page A8-288.

        S[d] = S[m];
    else
        for r = 0 to regs-1
            D[d+r] = D[m+r];
```

Exceptions

Undefined Instruction, Hyp Trap.

A8.8.341 VMOV (ARM core register to scalar)

This instruction copies a byte, halfword, or word from an ARM core register into an Advanced SIMD scalar.

On a Floating-point-only system, this instruction transfers one word to the upper or lower half of a double-precision floating-point register from an ARM core register. This is an identical operation to the Advanced SIMD single word transfer.

For more information about scalars see *Advanced SIMD scalars* on page A7-260.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of general controls of CP10 and CP11 functionality* on page B1-1230 and *Summary of access controls for Advanced SIMD functionality* on page B1-1232 summarize these controls.

Encoding T1/A1 Word version (`opc1:opc2 == '0x00'`): VFPv2, VFPv3, VFPv4, Advanced SIMD
Advanced SIMD otherwise

```
VMOV<c>.<size> <Dd[x]>, <Rt>
```

    when "1xxx"  advsimd = TRUE;  esize = 8;  index = UInt(opc1<0>:opc2);
    when "0xx1"  advsimd = TRUE;  esize = 16;  index = UInt(opc1<0>:opc2<1>);
    when "0x00"  advsimd = FALSE;  esize = 32;  index = UInt(opc1<0>);
    when "0x10"  UNDEFINED;
d = UInt(D:Vd);  t = UInt(Rt);
if t == 15 || (CurrentInstrSet() != InstrSet_ARM && t == 13) then UNPREDICTABLE;
```

Assembler syntax

```
VMOV{<c>}{<q>}{.<size>}  <Dd[x]>, <Rt>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287.

`<size>` The data size. It must be one of:

`8`	Encoded as `opc1<1>` = 1. `[x]` is encoded in `opc1<0>`, `opc2`.
`16`	Encoded as `opc1<1>` = 0, `opc2<0>` = 1. `[x]` is encoded in `opc1<0>`, `opc2<1>`.
`32`	Encoded as `opc1<1>` = 0, `opc2` = `0b00`. `[x]` is encoded in `opc1<0>`.
omitted	Equivalent to `32`.

`<Dd[x]>` The scalar. The register `<Dd>` is encoded in D:Vd. For details of how `[x]` is encoded, see the description of `<size>`.

`<Rt>` The source ARM core register.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDOrVFPEnabled(TRUE, advsimd);
    Elem[D[d],index,esize] = R[t]<esize-1:0>;
```

Exceptions

Undefined Instruction, Hyp Trap.

A8.8.342 VMOV (scalar to ARM core register)

This instruction copies a byte, halfword, or word from an Advanced SIMD scalar to an ARM core register. Bytes and halfwords can be either zero-extended or sign-extended.

On a Floating-point-only system, this instruction transfers one word from the upper or lower half of a double-precision floating-point register to an ARM core register. This is an identical operation to the Advanced SIMD single word transfer.

For more information about scalars see *Advanced SIMD scalars* on page A7-260.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of general controls of CP10 and CP11 functionality* on page B1-1230 and *Summary of access controls for Advanced SIMD functionality* on page B1-1232 summarize these controls.

VMOV{<c>}{<q>}  <Rt>, <Rt2>, <Dm>        Encoded as op = 1
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287.

`<Dm>` The doubleword extension register.

`<Rt>, <Rt2>` The two ARM core registers.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckVFPEnabled(TRUE);
    if to_arm_registers then
        R[t] = D[m]<31:0>;
        R[t2] = D[m]<63:32>;
    else
        D[m]<31:0> = R[t];
        D[m]<63:32> = R[t2];
```

Exceptions

Undefined Instruction, Hyp Trap.

A8.8.346 VMOVL

Vector Move Long takes each element in a doubleword vector, sign or zero-extends them to twice their original length, and places the results in a quadword vector.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page B1-1232 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see *Conditional execution* on page A8-288.

Encoding T1/A1 Advanced SIMD

```
VMOVL<c>.<dt> <Qd>, <Dm>

unsigned = (U == '1');  elements = 64 DIV esize;
d = UInt(D:Vd);  m = UInt(M:Vm);
```

Related encodings See *One register and a modified immediate value* on page A7-269.

Assembler syntax

```
VMOVL{<c>}{<q>}.dt  <Qd>, <Dm>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287. An ARM `VMOVL` instruction must be unconditional. ARM strongly recommends that a Thumb `VMOVL` instruction is unconditional, see *Conditional execution* on page A8-288.

`<dt>` The data type for the elements of the operand. It must be one of:

`S8`	Encoded as U = 0, imm3 = `0b001`.
`S16`	Encoded as U = 0, imm3 = `0b010`.
`S32`	Encoded as U = 0, imm3 = `0b100`.
`U8`	Encoded as U = 1, imm3 = `0b001`.
`U16`	Encoded as U = 1, imm3 = `0b010`.
`U32`	Encoded as U = 1, imm3 = `0b100`.

`<Qd>, <Dm>` The destination vector and the operand vector.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for e = 0 to elements-1
        result = Int(Elem[Din[m],e,esize], unsigned);
        Elem[Q[d>>1],e,2*esize] = result<2*esize-1:0>;
```

Exceptions

Undefined Instruction, Hyp Trap.

A8.8.347 VMOVN

Vector Move and Narrow copies the least significant half of each element of a quadword vector into the corresponding elements of a doubleword vector.

The operand vector elements can be any one of 16-bit, 32-bit, or 64-bit integers. There is no distinction between signed and unsigned integers.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page B1-1232 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see *Conditional execution* on page A8-288.

Encoding T1/A1 Advanced SIMD

```
t = UInt(Rt);
if t == 13 && CurrentInstrSet() != InstrSet_ARM then UNPREDICTABLE;
```

Assembler syntax

```
VMRS{<c>}{<q>}  <Rt>, FPSCR
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287.

`<Rt>` The destination ARM core register. This register can be R0-R14 or APSR_nzcv. APSR_nzcv is encoded as Rt = `0b1111`, and the instruction transfers the FPSCR.{N, Z, C, V} condition flags to the APSR.{N, Z, C, V} condition flags.

The pre-UAL instruction `FMSTAT` is equivalent to `VMRS APSR_nzcv, FPSCR`.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckVFPEnabled(TRUE);
    SerializeVFP();  VFPExcBarrier();
    if t != 15 then
        R[t] = FPSCR;
    else
        APSR.N = FPSCR.N;
        APSR.Z = FPSCR.Z;
        APSR.C = FPSCR.C;
        APSR.V = FPSCR.V;
```

Exceptions

Undefined Instruction, Hyp Trap.

A8.8.349 VMSR

Move to Advanced SIMD and Floating-point Extension System Register from ARM core register moves the value of an ARM core register to the FPSCR.

For details of system level use of this instruction, see *VMSR* on page B9-2014.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of general controls of CP10 and CP11 functionality* on page B1-1230 and *Summary of access controls for Advanced SIMD functionality* on page B1-1232 summarize these controls.

Encoding T1/A1 VFPv2, VFPv3, VFPv4, Advanced SIMD

```
VMSR<c> FPSCR, <Rt>
```

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Assembler syntax

`VMUL{<c>}{<q>}.<dt>  {<Qd>,} <Qn>, <Dm[x]>`	Encoding T1/A1, encoded as Q = 1
`VMUL{<c>}{<q>}.<dt>  {<Dd>,} <Dn>, <Dm[x]>`	Encoding T1/A1, encoded as Q = 0
`VMULL{<c>}{<q>}.<dt>  <Qd>, <Dn>, <Dm[x]>`	Encoding T2/A2

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287. An ARM Advanced SIMD `VMUL` or `VMULL` instruction must be unconditional. ARM strongly recommends that a Thumb Advanced SIMD `VMUL` or `VMULL` instruction is unconditional, see *Conditional execution* on page A8-288.

`<dt>` The data type for the scalar, and the elements of the operand vector. It must be one of:

- `I16` Encoding T1/A1, encoded as size = `0b01`, F = 0.
- `I32` Encoding T1/A1, encoded as size = `0b10`, F = 0.
- `F32` Encoding T1/A1, encoded as size = `0b10`, F = 1.
- `S16` Encoding T2/A2, encoded as size = `0b01`, U = 0.
- `S32` Encoding T2/A2, encoded as size = `0b10`, U = 0.
- `U16` Encoding T2/A2, encoded as size = `0b01`, U = 1.
- `U32` Encoding T2/A2, encoded as size = `0b10`, U = 1.

`<Qd>, <Qn>` The destination vector, and the operand vector, for a quadword operation.

`<Dd>, <Dn>` The destination vector, and the operand vector, for a doubleword operation.

`<Qd>, <Dn>` The destination vector, and the operand vector, for a long operation.

`<Dm[x]>` The scalar. `Dm` is restricted to D0-D7 if `<dt>` is `I16`, `S16`, or `U16`, or D0-D15 otherwise.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    op2 = Elem[Din[m],index,esize];  op2val = Int(op2, unsigned);
    for r = 0 to regs-1
        for e = 0 to elements-1
            op1 = Elem[Din[n+r],e,esize];  op1val = Int(op1, unsigned);
            if floating_point then
                Elem[D[d+r],e,esize] = FPMul(op1, op2, FALSE);
            else
                if long_destination then
                    Elem[Q[d>>1],e,2*esize] = (op1val*op2val)<2*esize-1:0>;
                else
                    Elem[D[d+r],e,esize] = (op1val*op2val)<esize-1:0>;
```

Exceptions

Undefined Instruction, Hyp Trap.

Floating-point exceptions

Input Denormal, Invalid Operation, Overflow, Underflow, Inexact.

A8.8.353 VMVN (immediate)

Vector Bitwise NOT (immediate) places the bitwise inverse of an immediate integer constant into every element of the destination register. For the range of constants available, see *One register and a modified immediate value* on page A7-269.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page B1-1232 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see *Conditional execution* on page A8-288.

Encoding T1/A1 Advanced SIMD

Assembler syntax

`VMVN{<c>}{<q>}.dt  <Qd>, #<imm>`	Encoding T1/A1, encoded as Q = 1
`VMVN{<c>}{<q>}.dt  <Dd>, #<imm>`	Encoding T1/A1, encoded as Q = 0

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287. An ARM `VMVN` instruction must be unconditional. ARM strongly recommends that a Thumb `VMVN` instruction is unconditional, see *Conditional execution* on page A8-288.

`<dt>` The data type. It must be either `I16` or `I32`.

`<Qd>` The destination register for a quadword operation.

`<Dd>` The destination register for a doubleword operation.

`<imm>` A constant of the specified type.

See *One register and a modified immediate value* on page A7-269 for the range of constants available, and the encoding of `<dt>` and `<imm>`.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        D[d+r] = NOT(imm64);
```

Exceptions

Undefined Instruction, Hyp Trap.

Pseudo-instructions

One register and a modified immediate value on page A7-269 describes pseudo-instructions with a combination of `<dt>` and `<imm>` that is not supported by hardware, but that generates the same destination register value as a different combination that is supported by hardware.

A8.8.354 VMVN (register)

Vector Bitwise NOT (register) takes a value from a register, inverts the value of each bit, and places the result in the destination register. The registers can be either doubleword or quadword.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page B1-1232 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see *Conditional execution* on page A8-288.

    else             // VFP instruction
        if dp_operation then
            D[d] = FPNeg(D[m]);
        else
            S[d] = FPNeg(S[m]);
```

Exceptions

Undefined Instruction, Hyp Trap.

A8.8.356 VNMLA, VNMLS, VNMUL

VNMLA multiplies together two floating-point register values, adds the negation of the floating-point value in the destination register to the negation of the product, and writes the result back to the destination register.

VNMLS multiplies together two floating-point register values, adds the negation of the floating-point value in the destination register to the product, and writes the result back to the destination register.

VNMUL multiplies together two floating-point register values, and writes the negation of the result to the destination register.

Note

ARM recommends that software does not use the VNMLA instruction in the *Round towards Plus Infinity* and *Round towards Minus Infinity* rounding modes, because the rounding of the product and of the sum can change the result of the instruction in opposite directions, defeating the purpose of these rounding modes.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of general controls of CP10 and CP11 functionality* on page B1-1230 summarizes these controls.

Assembler syntax

`VORN{<c>}{<q>}{.<dt>}  {<Qd>,} <Qn>, <Qm>`	Encoded as Q = 1
`VORN{<c>}{<q>}{.<dt>}  {<Dd>,} <Dn>, <Dm>`	Encoded as Q = 0

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287. An ARM `VORN` instruction must be unconditional. ARM strongly recommends that a Thumb `VORN` instruction is unconditional, see *Conditional execution* on page A8-288.

`<dt>` An optional data type. It is ignored by assemblers, and does not affect the encoding.

`<Qd>, <Qn>, <Qm>` The destination vector and the operand vectors, for a quadword operation.

`<Dd>, <Dn>, <Dm>` The destination vector and the operand vectors, for a doubleword operation.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        D[d+r] = D[n+r] OR NOT(D[m+r]);
```

Exceptions

Undefined Instruction, Hyp Trap.

A8.8.359 VORR (immediate)

This instruction takes the contents of the destination vector, performs a bitwise OR with an immediate constant, and returns the result into the destination vector. For the range of constants available, see *One register and a modified immediate value* on page A7-269.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page B1-1232 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see *Conditional execution* on page A8-288.

Encoding T1/A1 Advanced SIMD

```
VORR<c>.<dt> <Qd>, #<imm>
VORR<c>.<dt> <Dd>, #<imm>
```

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

imm64 = AdvSIMDExpandImm('0', cmode, i:imm3:imm4);
d = UInt(D:Vd);  regs = if Q == '0' then 1 else 2;
```

Assembler syntax

`VORR{<c>}{<q>}.<dt>  {<Qd>,} <Qd>, #<imm>`	Encoded as Q = 1
`VORR{<c>}{<q>}.<dt>  {<Dd>,} <Dd>, #<imm>>`	Encoded as Q = 0

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287. An ARM `VORR` instruction must be unconditional. ARM strongly recommends that a Thumb `VORR` instruction is unconditional, see *Conditional execution* on page A8-288.

`<dt>` The data type used for `<imm>`. It can be either `I16` or `I32`.

`I8`, `I64`, and `F32` are also permitted, but the resulting syntax is a pseudo-instruction.

`<Qd>` The destination vector for a quadword operation.

`<Dd>` The destination vector for a doubleword operation.

`<imm>` A constant of the type specified by `<dt>`. This constant is replicated enough times to fill the destination register. For example, `VORR.I32 D0, #10` ORs `0x0000000A0000000A` into D0.

For details of the range of constants available, and the encoding of `<dt>` and `<imm>`, see *One register and a modified immediate value* on page A7-269.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        D[d+r] = D[d+r] OR imm64;
```

Exceptions

Undefined Instruction, Hyp Trap.

Pseudo-instructions

`VORN` can be used, with a range of constants that are the bitwise inverse of the available constants for `VORR`. This is assembled as the equivalent `VORR` instruction. Disassembly produces the `VORR` form.

One register and a modified immediate value on page A7-269 describes pseudo-instructions with a combination of `<dt>` and `<imm>` that is not supported by hardware, but that generates the same destination register value as a different combination that is supported by hardware.

A8.8.360 VORR (register)

This instruction performs a bitwise OR operation between two registers, and places the result in the destination register. The operand and result registers can be quadword or doubleword. They must all be the same size.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page B1-1232 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see *Conditional execution* on page A8-288.

`<dt>` An optional data type. It is ignored by assemblers, and does not affect the encoding.

`<Qd>, <Qn>, <Qm>` The destination vector and the operand vectors, for a quadword operation.

`<Dd>, <Dn>, <Dm>` The destination vector and the operand vectors, for a doubleword operation.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        D[d+r] = D[n+r] OR D[m+r];
```

Exceptions

Undefined Instruction, Hyp Trap.

A8.8.361 VPADAL

Vector Pairwise Add and Accumulate Long adds adjacent pairs of elements of a vector, and accumulates the results into the elements of the destination vector.

The vectors can be doubleword or quadword. The operand elements can be 8-bit, 16-bit, or 32-bit integers. The result elements are twice the length of the operand elements.

Figure A8-2 shows an example of the operation of VPADAL.

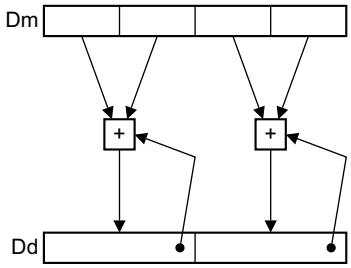

Figure A8-2 VPADAL doubleword operation for data type S16

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page B1-1232 summarizes these controls.

- `U16` Encoding T1/A1, encoded as size = `0b01`, U = 1.
- `U32` Encoding T1/A1, encoded as size = `0b10`, U = 1.

`<Dd>, <Dn>, <Dm>` The destination vector and the operand vectors.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    bits(64) dest;
    h = elements/2;

    for e = 0 to h-1
        op1 = Int(Elem[D[n],2*e,esize], unsigned);
        op2 = Int(Elem[D[n],2*e+1,esize], unsigned);
        result = if maximum then Max(op1,op2) else Min(op1,op2);
        Elem[dest,e,esize] = result<esize-1:0>;
        op1 = Int(Elem[D[m],2*e,esize], unsigned);
        op2 = Int(Elem[D[m],2*e+1,esize], unsigned);
        result = if maximum then Max(op1,op2) else Min(op1,op2);
        Elem[dest,e+h,esize] = result<esize-1:0>;

    D[d] = dest;
```

Exceptions

Undefined Instruction, Hyp Trap.

A8.8.366 VPMAX, VPMIN (floating-point)

Vector Pairwise Maximum compares adjacent pairs of elements in two doubleword vectors, and copies the larger of each pair into the corresponding element in the destination doubleword vector.

Vector Pairwise Minimum compares adjacent pairs of elements in two doubleword vectors, and copies the smaller of each pair into the corresponding element in the destination doubleword vector.

Figure A8-5 on page A8-986 shows an example of the operation of VPMAX.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page B1-1232 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see *Conditional execution* on page A8-288.

Encoding T1/A1 Advanced SIMD (UNDEFINED in integer-only variant)

regs = UInt(imm8);
if regs == 0 || (d+regs) > 32 then UNPREDICTABLE;
```

FLDMX Encoding T1/A1 behaves as described by the pseudocode if imm8 is odd. However, there is no UAL syntax for such encodings and ARM deprecates their use. For more information, see *FLDMX, FSTMX* on page A8-388.

Assembler syntax

```
VPOP{<c>}{<q>}{.<size>}  <list>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287.

`<size>` An optional data size specifier. If present, it must be equal to the size in bits, 32 or 64, of the registers in `<list>`.

`<list>` The extension registers to be loaded, as a list of consecutively numbered doubleword (encoding T1/A1) or singleword (encoding T2/A2) registers, separated by commas and surrounded by brackets. It is encoded in the instruction by setting D and Vd to specify the first register in the list, and imm8 to twice the number of registers in the list (encoding T1/A1) or the number of registers in the list (encoding T2/A2). `<list>` must contain at least one register, and not more than sixteen.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckVFPEnabled(TRUE);  NullCheckIfThumbEE(13);
    address = SP;
    SP = SP + imm32;
    if single_regs then
        for r = 0 to regs-1
            S[d+r] = MemA[address,4];  address = address+4;
    else
        for r = 0 to regs-1
            word1 = MemA[address,4];  word2 = MemA[address+4,4];  address = address+8;
            // Combine the word-aligned words in the correct order for current endianness.
            D[d+r] = if BigEndian() then word1:word2 else word2:word1;
```

Exceptions

Undefined Instruction, Hyp Trap, Data Abort.

A8.8.368 VPUSH

Vector Push stores multiple consecutive extension registers to the stack.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of general controls of CP10 and CP11 functionality* on page B1-1230 and *Summary of access controls for Advanced SIMD functionality* on page B1-1232 summarize these controls.

- `MLAL` Encoded as op = 0.
- `MLSL` Encoded as op = 1.

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287. An ARM `VQDMLAL` or `VQDMLSL` instruction must be unconditional. ARM strongly recommends that a Thumb `VQDMLAL` or `VQDMLSL` instruction is unconditional, see *Conditional execution* on page A8-288.

`<dt>` The data type for the elements of the operands. It must be one of:

- `S16` Encoded as size = `0b01`.
- `S32` Encoded as size = `0b10`.

`<Qd>, <Dn>` The destination vector and the first operand vector.

`<Dm>` The second operand vector, for an all vector operation.

`<Dm[x]>` The scalar for a scalar operation. If `<dt>` is `S16`, `Dm` is restricted to D0-D7. If `<dt>` is `S32`, `Dm` is restricted to D0-D15.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    if scalar_form then op2 = SInt(Elem[Din[m],index,esize]);
    for e = 0 to elements-1
        if !scalar_form then op2 = SInt(Elem[Din[m],e,esize]);
        op1 = SInt(Elem[Din[n],e,esize]);
        // The following only saturates if both op1 and op2 equal -(2^(esize-1))
        (product, sat1) = SignedSatQ(2*op1*op2, 2*esize);
        if add then
            result = SInt(Elem[Qin[d>>1],e,2*esize]) + SInt(product);
        else
            result = SInt(Elem[Qin[d>>1],e,2*esize]) - SInt(product);
        (Elem[Q[d>>1],e,2*esize], sat2) = SignedSatQ(result, 2*esize);
        if sat1 || sat2 then FPSCR.QC = '1';
```

Exceptions

Undefined Instruction, Hyp Trap.

A8.8.372 VQDMULH

Vector Saturating Doubling Multiply Returning High Half multiplies corresponding elements in two vectors, doubles the results, and places the most significant half of the final results in the destination vector. The results are truncated (for rounded results see *VQRDMULH* on page A8-1008).

The second operand can be a scalar instead of a vector. For more information about scalars see *Advanced SIMD scalars* on page A7-260.

If any of the results overflow, they are saturated. The cumulative saturation bit, FPSCR.QC, is set if saturation occurs. For details see *Pseudocode details of saturation* on page A2-44.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page B1-1232 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see *Conditional execution* on page A8-288.

        if sat then FPSCR.QC = '1';
```

Exceptions

Undefined Instruction, Hyp Trap.

A8.8.374 VQMOVN, VQMOVUN

Vector Saturating Move and Narrow copies each element of the operand vector to the corresponding element of the destination vector.

The operand is a quadword vector. The elements can be any one of:

- 16-bit, 32-bit, or 64-bit signed integers
- 16-bit, 32-bit, or 64-bit unsigned integers.

The result is a doubleword vector. The elements are half the length of the operand vector elements. If the operand is unsigned, the results are unsigned. If the operand is signed, the results can be signed or unsigned.

If any of the results overflow, they are saturated. The cumulative saturation bit, FPSCR.QC, is set if saturation occurs. For details see *Pseudocode details of saturation* on page A2-44.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page B1-1232 summarizes these controls.

```

Assembler syntax

```
VQMOV{U}N{<c>}{<q>}.<type><size>  <Dd>, <Qm>
```

where:

`U` If present, specifies that the operation produces unsigned results, even though the operands are signed. Encoded as op = `0b01`.

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287. An ARM `VQMOVN` or `VQMOVUN` instruction must be unconditional. ARM strongly recommends that a Thumb `VQMOVN` or `VQMOVUN` instruction is unconditional, see *Conditional execution* on page A8-288.

`<type>` The data type for the elements of the operand. It must be one of:

- `S` Encoded as:
  - op = `0b10` for `VQMOVN`.
  - op = `0b01` for `VQMOVUN`.
- `U` Encoded as op = `0b11`. Not available for `VQMOVUN`.

`<size>` The data size for the elements of the operand. It must be one of:

- `16` Encoded as size = `0b00`.
- `32` Encoded as size = `0b01`.
- `64` Encoded as size = `0b10`.

`<Dd>, <Qm>` The destination vector and the operand vector.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for e = 0 to elements-1
        operand = Int(Elem[Qin[m>>1],e,2*esize], src_unsigned);
        (Elem[D[d],e,esize], sat) = SatQ(operand, esize, dest_unsigned);
        if sat then FPSCR.QC = '1';
```

Exceptions

Undefined Instruction, Hyp Trap.

A8.8.375 VQNEG

Vector Saturating Negate negates each element in a vector, and places the results in the destination vector.

If any of the results overflow, they are saturated. The cumulative saturation bit, FPSCR.QC, is set if saturation occurs. For details see *Pseudocode details of saturation* on page A2-44.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page B1-1232 summarizes these controls.

`VQRDMULH{<c>}{<q>}.<dt>  {<Dd>,} <Dn>, <Dm[x]>`	Encoding T2/A2, encoded as Q = 0

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287. An ARM `VQRDMULH` instruction must be unconditional. ARM strongly recommends that a Thumb `VQRDMULH` instruction is unconditional, see *Conditional execution* on page A8-288.

`<dt>` The data type for the elements of the operands. It must be one of:

- `S16` Encoded as size = `0b01`.
- `S32` Encoded as size = `0b10`.

`<Qd>, <Qn>` The destination vector and the first operand vector, for a quadword operation.

`<Dd>, <Dn>` The destination vector and the first operand vector, for a doubleword operation.

`<Qm>` The second operand vector, for a quadword all vector operation.

`<Dm>` The second operand vector, for a doubleword all vector operation.

`<Dm[x]>` The scalar for either a quadword or a doubleword scalar operation. If `<dt>` is `S16`, `Dm` is restricted to D0-D7. If `<dt>` is `S32`, `Dm` is restricted to D0-D15.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    round_const = 1 << (esize-1);
    if scalar_form then op2 = SInt(Elem[D[m],index,esize]);
    for r = 0 to regs-1
        for e = 0 to elements-1
            op1 = SInt(Elem[D[n+r],e,esize]);
            if !scalar_form then op2 = SInt(Elem[D[m+r],e,esize]);
            (result, sat) = SignedSatQ((2*op1*op2 + round_const) >> esize, esize);
            Elem[D[d+r],e,esize] = result;
            if sat then FPSCR.QC = '1';
```

Exceptions

Undefined Instruction, Hyp Trap.

A8.8.377 VQRSHL

Vector Saturating Rounding Shift Left takes each element in a vector, shifts them by a value from the least significant byte of the corresponding element of a second vector, and places the results in the destination vector. If the shift value is positive, the operation is a left shift. Otherwise, it is a right shift.

For truncated results see *VQSHL (register)* on page A8-1014.

The first operand and result elements are the same data type, and can be any one of:

- 8-bit, 16-bit, 32-bit, or 64-bit signed integers
- 8-bit, 16-bit, 32-bit, or 64-bit unsigned integers.

The second operand is a signed integer of the same size.

If any of the results overflow, they are saturated. The cumulative saturation bit, FPSCR.QC, is set if saturation occurs. For details see *Pseudocode details of saturation* on page A2-44.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page B1-1232 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see *Conditional execution* on page A8-288.

VQSUB{<c>}{<q>}.<type><size>  {<Dd>,} <Dn>, <Dm>        Encoded as Q = 0
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287. An ARM `VQSUB` instruction must be unconditional. ARM strongly recommends that a Thumb `VQSUB` instruction is unconditional, see *Conditional execution* on page A8-288.

`<type>` The data type for the elements of the vectors. It must be one of:

- `S` Signed, encoded as U = 0.
- `U` Unsigned, encoded as U = 1.

`<size>` The data size for the elements of the vectors. It must be one of:

- `8` Encoded as size = `0b00`.
- `16` Encoded as size = `0b01`.
- `32` Encoded as size = `0b10`.
- `64` Encoded as size = `0b11`.

`<Qd>, <Qn>, <Qm>` The destination vector and the operand vectors, for a quadword operation.

`<Dd>, <Dn>, <Dm>` The destination vector and the operand vectors, for a doubleword operation.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        for e = 0 to elements-1
            diff = Int(Elem[D[n+r],e,esize], unsigned) - Int(Elem[D[m+r],e,esize], unsigned);
            (Elem[D[d+r],e,esize], sat) = SatQ(diff, esize, unsigned);
            if sat then FPSCR.QC = '1';
```

Exceptions

Undefined Instruction, Hyp Trap.

A8.8.383 VRADDHN

Vector Rounding Add and Narrow, returning High Half adds corresponding elements in two quadword vectors, and places the most significant half of each result in a doubleword vector. The results are rounded. (For truncated results, see *VADDHN* on page A8-832.)

The operand elements can be 16-bit, 32-bit, or 64-bit integers. There is no distinction between signed and unsigned integers.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page B1-1232 summarizes these controls.

`<dt>` The data type for the elements of the operands. It must be one of:

- `I16` Encoded as size = `0b00`.
- `I32` Encoded as size = `0b01`.
- `I64` Encoded as size = `0b10`.

`<Dd>, <Qn>, <Qm>` The destination vector and the operand vectors.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    round_const = 1 << (esize-1);
    for e = 0 to elements-1
        result = Elem[Qin[n>>1],e,2*esize] + Elem[Qin[m>>1],e,2*esize] + round_const;
        Elem[D[d],e,esize] = result<2*esize-1:esize>;
```

Exceptions

Undefined Instruction, Hyp Trap.

A8.8.384 VRECPE

Vector Reciprocal Estimate finds an approximate reciprocal of each element in the operand vector, and places the results in the destination vector.

The operand and result elements are the same type, and can be 32-bit floating-point numbers, or 32-bit unsigned integers.

For details of the operation performed by this instruction see *Floating-point reciprocal estimate and step* on page A2-85.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page B1-1232 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see *Conditional execution* on page A8-288.

A8.8.386 VREV16, VREV32, VREV64

VREV16 (Vector Reverse in halfwords) reverses the order of 8-bit elements in each halfword of the vector, and places the result in the corresponding destination vector.

VREV32 (Vector Reverse in words) reverses the order of 8-bit or 16-bit elements in each word of the vector, and places the result in the corresponding destination vector.

VREV64 (Vector Reverse in doublewords) reverses the order of 8-bit, 16-bit, or 32-bit elements in each doubleword of the vector, and places the result in the corresponding destination vector.

There is no distinction between data types, other than size.

Figure A8-6 shows two examples of the operation of VREV.

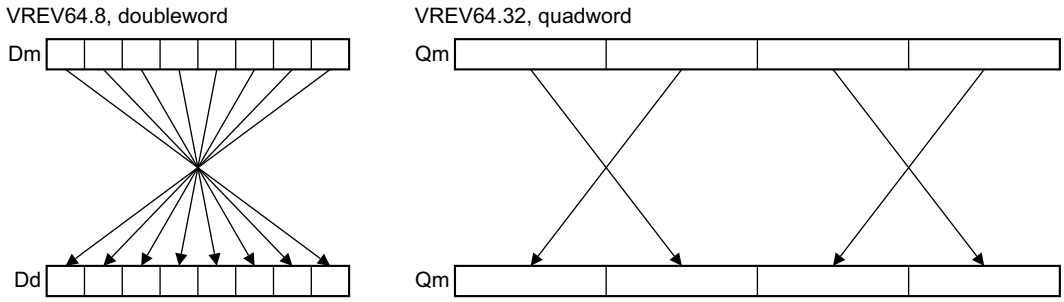

Figure A8-6 VREV operation examples

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page B1-1232 summarizes these controls.

`U32`	Encoded as size = `0b10`, U = 1.

`<Qd>, <Qn>, <Qm>` The destination vector and the operand vectors, for a quadword operation.

`<Dd>, <Dn>, <Dm>` The destination vector and the operand vectors, for a doubleword operation.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        for e = 0 to elements-1
            op1 = Int(Elem[D[n+r],e,esize], unsigned);
            op2 = Int(Elem[D[m+r],e,esize], unsigned);
            result = op1 + op2 + 1;
            Elem[D[d+r],e,esize] = result<esize:1>;
```

Exceptions

Undefined Instruction, Hyp Trap.

A8.8.388 VRSHL

Vector Rounding Shift Left takes each element in a vector, shifts them by a value from the least significant byte of the corresponding element of a second vector, and places the results in the destination vector. If the shift value is positive, the operation is a left shift. If the shift value is negative, it is a rounding right shift. (For a truncating shift, see *VSHL (register)* on page A8-1048).

The first operand and result elements are the same data type, and can be any one of:

- 8-bit, 16-bit, 32-bit, or 64-bit signed integers
- 8-bit, 16-bit, 32-bit, or 64-bit unsigned integers.

The second operand is always a signed integer of the same size.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page B1-1232 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see *Conditional execution* on page A8-288.

```

Related encodings See *One register and a modified immediate value* on page A7-269.

Assembler syntax

```
VRSHR{<c>}{<q>}.<type><size>  {<Qd>,} <Qm>, #<imm>        Encoded as Q = 1
VRSHR{<c>}{<q>}.<type><size>  {<Dd>,} <Dm>, #<imm>        Encoded as Q = 0
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287. An ARM `VRSHR` instruction must be unconditional. ARM strongly recommends that a Thumb `VRSHR` instruction is unconditional, see *Conditional execution* on page A8-288.

`<type>` The data type for the elements of the vectors. It must be one of:

- `S` Signed, encoded as U = 0
- `U` Unsigned, encoded as U = 1.

`<size>` The data size for the elements of the vectors. It must be one of:

- `8` Encoded as L = 0, imm6<5:3> = `0b001`. (8 – `<imm>`) is encoded in imm6<2:0>.
- `16` Encoded as L = 0, imm6<5:4> = `0b01`. (16 – `<imm>`) is encoded in imm6<3:0>.
- `32` Encoded as L = 0, imm6<5> = `0b1`. (32 – `<imm>`) is encoded in imm6<4:0>.
- `64` Encoded as L = 1. (64 – `<imm>`) is encoded in imm6<5:0>.

`<Qd>, <Qm>` The destination vector, and the operand vector, for a quadword operation.

`<Dd>, <Dm>` The destination vector, and the operand vector, for a doubleword operation.

`<imm>` The immediate value, in the range 1 to `<size>`. See the description of `<size>` for how `<imm>` is encoded.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    round_const = 1 << (shift_amount - 1);
    for r = 0 to regs-1
        for e = 0 to elements-1
            result = (Int(Elem[D[m+r],e,esize], unsigned) + round_const) >> shift_amount;
            Elem[D[d+r],e,esize] = result<esize-1:0>;
```

Exceptions

Undefined Instruction, Hyp Trap.

Pseudo-instructions

```
VRSHR.<type><size>  <Qd>, <Qm>, #0      is a synonym for    VMOV <Qd>, <Qm>
VRSHR.<type><size>  <Dd>, <Dm>, #0      is a synonym for    VMOV <Dd>, <Dm>
```

For details see *VMOV (register)* on page A8-938.

A8.8.390 VRSHRN

Vector Rounding Shift Right and Narrow takes each element in a vector, right shifts them by an immediate value, and places the rounded results in the destination vector. For truncated results, see *VSHRN* on page A8-1054.

The operand elements can be 16-bit, 32-bit, or 64-bit integers. There is no distinction between signed and unsigned integers. The destination elements are half the size of the source elements.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page B1-1232 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see *Conditional execution* on page A8-288.

Encoding T1/A1 Advanced SIMD

```

Related encodings See *One register and a modified immediate value* on page A7-269.

Assembler syntax

```
VRSHRN{<c>}{<q>}.I<size>  <Dd>, <Qm>, #<imm>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287. An ARM `VRSHRN` instruction must be unconditional. ARM strongly recommends that a Thumb `VRSHRN` instruction is unconditional, see *Conditional execution* on page A8-288.

`<size>` The data size for the elements of the vectors. It must be one of:

- `16` Encoded as imm6<5:3> = `0b001`. (8 – <imm>) is encoded in imm6<2:0>.
- `32` Encoded as imm6<5:4> = `0b01`. (16 – <imm>) is encoded in imm6<3:0>.
- `64` Encoded as imm6<5> = `0b1`. (32 – <imm>) is encoded in imm6<4:0>.

`<Dd>, <Qm>` The destination vector, and the operand vector.

`<imm>` The immediate value, in the range 1 to <size>/2. See the description of <size> for how <imm> is encoded.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    round_const = 1 << (shift_amount-1);
    for e = 0 to elements-1
        result = LSR(Elem[Qin[m>>1],e,2*esize] + round_const, shift_amount);
        Elem[D[d],e,esize] = result<esize-1:0>;
```

Exceptions

Undefined Instruction, Hyp Trap.

Pseudo-instructions

`VRSHRN.I<size>  <Dd>, <Qm>, #0` is a synonym for `VMOVN.I<size> <Dd>, <Qm>`

For details see *VMOVN* on page A8-952.

A8.8.391 VRSQRTE

Vector Reciprocal Square Root Estimate finds an approximate reciprocal square root of each element in a vector, and places the results in a second vector.

The operand and result elements are the same type, and can be 32-bit floating-point numbers, or 32-bit unsigned integers.

For details of the operation performed by this instruction see *Floating-point reciprocal square root estimate and step* on page A2-87.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page B1-1232 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see *Conditional execution* on page A8-288.

Encoding T1/A1

            else
                Elem[D[d+r],e,esize] = UnsignedRSqrtEstimate(Elem[D[m+r],e,esize]);
```

Exceptions

Undefined Instruction, Hyp Trap.

Floating-point exceptions

Input Denormal, Invalid Operation, Division by Zero.

Newton-Raphson iteration

For details of the operation performed and how it can be used in a Newton-Raphson iteration to calculate the reciprocal of the square root of a number, see *Floating-point reciprocal square root estimate and step* on page A2-87.

A8.8.392 VRSQRTS

Vector Reciprocal Square Root Step multiplies the elements of one vector by the corresponding elements of another vector, subtracts each of the products from 3.0, divides these results by 2.0, and places the results into the elements of the destination vector.

The operand and result elements are 32-bit floating-point numbers.

For details of the operation performed by this instruction see *Floating-point reciprocal square root estimate and step* on page A2-87.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page B1-1232 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see *Conditional execution* on page A8-288.

Newton-Raphson iteration

For details of the operation performed and how it can be used in a Newton-Raphson iteration to calculate the reciprocal of the square root of a number, see *Floating-point reciprocal square root estimate and step* on page A2-87.

A8.8.393 VRSRA

Vector Rounding Shift Right and Accumulate takes each element in a vector, right shifts them by an immediate value, and accumulates the rounded results into the destination vector. (For truncated results, see *VSRA* on page A8-1060.)

The operand and result elements must all be the same type, and can be any one of:

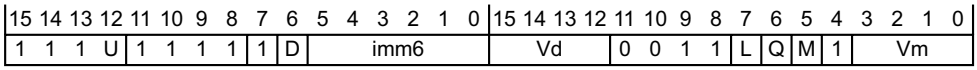
- 8-bit, 16-bit, 32-bit, or 64-bit signed integers.
- 8-bit, 16-bit, 32-bit, or 64-bit unsigned integers.

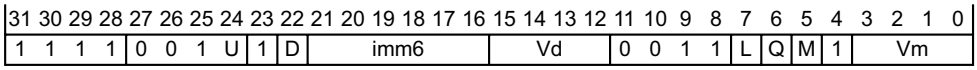
Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page B1-1232 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see *Conditional execution* on page A8-288.

Encoding T1/A1 Advanced SIMD

```
VRSRA<c>.<type><size> <Qd>, <Qm>, #<imm>
VRSRA<c>.<type><size> <Dd>, <Dm>, #<imm>
```





```
if (L:imm6) IN "0000xxx" then SEE "Related encodings";
if Q == '1' && (Vd<0> == '1' || Vm<0> == '1') then UNDEFINED;
case L:imm6 of
    when "0001xxx"  esize = 8;  elements = 8;  shift_amount = 16 - UInt(imm6);
    when "001xxxx"  esize = 16;  elements = 4;  shift_amount = 32 - UInt(imm6);
    when "01xxxxx"  esize = 32;  elements = 2;  shift_amount = 64 - UInt(imm6);
    when "1xxxxxx"  esize = 64;  elements = 1;  shift_amount = 64 - UInt(imm6);
unsigned = (U == '1');  d = UInt(D:Vd);  m = UInt(M:Vm);  regs = if Q == '0' then 1 else 2;
```

Related encodings See *One register and a modified immediate value* on page A7-269.

Assembler syntax

`VRSRA{<c>}{<q>}.<type><size>  {<Qd>,} <Qm>, #<imm>`	Encoded as Q = 1
`VRSRA{<c>}{<q>}.<type><size>  {<Dd>,} <Dm>, #<imm>`	Encoded as Q = 0

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287. An ARM `VRSRA` instruction must be unconditional. ARM strongly recommends that a Thumb `VRSRA` instruction is unconditional, see *Conditional execution* on page A8-288.

`<type>` The data type for the elements of the vectors. It must be one of:

- `S` Signed, encoded as U = 0.
- `U` Unsigned, encoded as U = 1.

`<size>` The data size for the elements of the vectors. It must be one of:

- `8` Encoded as L = 0, imm6<5:3> = `0b001`. (8 – `<imm>`) is encoded in imm6<2:0>.
- `16` Encoded as L = 0, imm6<5:4> = `0b01`. (16 – `<imm>`) is encoded in imm6<3:0>.
- `32` Encoded as L = 0, imm6<5> = `0b1`. (32 – `<imm>`) is encoded in imm6<4:0>.
- `64` Encoded as L = 1. (64 – `<imm>`) is encoded in imm6<5:0>.

`<Qd>, <Qm>` The destination vector, and the operand vector, for a quadword operation.

`<Dd>, <Dm>` The destination vector, and the operand vector, for a doubleword operation.

`<imm>` The immediate value, in the range 1 to `<size>`. See the description of `<size>` for how `<imm>` is encoded.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    round_const = 1 << (shift_amount - 1);
    for r = 0 to regs-1
        for e = 0 to elements-1
            result = (Int(Elem[D[m+r],e,esize], unsigned) + round_const) >> shift_amount;
            Elem[D[d+r],e,esize] = Elem[D[d+r],e,esize] + result;
```

Exceptions

Undefined Instruction, Hyp Trap.

A8.8.394 VRSUBHN

Vector Rounding Subtract and Narrow, returning High Half subtracts the elements of one quadword vector from the corresponding elements of another quadword vector takes the most significant half of each result, and places the final results in a doubleword vector. The results are rounded. (For truncated results, see *VSUBHN* on page A8-1088.)

The operand elements can be 16-bit, 32-bit, or 64-bit integers. There is no distinction between signed and unsigned integers.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page B1-1232 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see *Conditional execution* on page A8-288.

Encoding T1/A1 Advanced SIMD

- `64` Encoded as L = 1. `<imm>` is encoded in imm6<5:0>.

`<Qd>, <Qm>` The destination vector, and the operand vector, for a quadword operation.

`<Dd>, <Dm>` The destination vector, and the operand vector, for a doubleword operation.

`<imm>` The immediate value, in the range 0 to `<size>`-1. See the description of `<size>` for how `<imm>` is encoded.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        for e = 0 to elements-1
            Elem[D[d+r],e,esize] = LSL(Elem[D[m+r],e,esize], shift_amount);
```

Exceptions

Undefined Instruction, Hyp Trap.

A8.8.396 VSHL (register)

Vector Shift Left (register) takes each element in a vector, shifts them by a value from the least significant byte of the corresponding element of a second vector, and places the results in the destination vector. If the shift value is positive, the operation is a left shift. If the shift value is negative, it is a truncating right shift.

Note

For a rounding shift, see *VRSHL* on page A8-1032.

The first operand and result elements are the same data type, and can be any one of:

- 8-bit, 16-bit, 32-bit, or 64-bit signed integers
- 8-bit, 16-bit, 32-bit, or 64-bit unsigned integers.

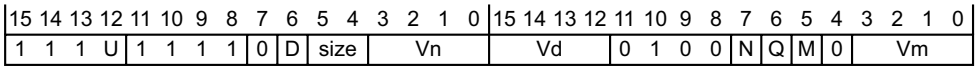
The second operand is always a signed integer of the same size.

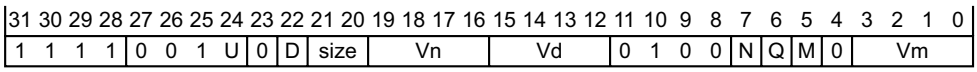
Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page B1-1232 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see *Conditional execution* on page A8-288.

Encoding T1/A1 Advanced SIMD

```
VSHL<c>.<type><size> <Qd>, <Qm>, <Qn>
VSHL<c>.<type><size> <Dd>, <Dm>, <Dn>
```





```
if Q == '1' && (Vd<0> == '1' || Vm<0> == '1' || Vn<0> == '1') then UNDEFINED;
unsigned = (U == '1');
esize = 8 << UInt(size);  elements = 64 DIV esize;
d = UInt(D:Vd);  m = UInt(M:Vm);  n = UInt(N:Vn);  regs = if Q == '0' then 1 else 2;
```

Assembler syntax

`VSHL{<c>}{<q>}.<type><size>  {<Qd>,} <Qm>, <Qn>`	Encoded as Q = 1
`VSHL{<c>}{<q>}.<type><size>  {<Dd>,} <Dm>, <Dn>`	Encoded as Q = 0

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287. An ARM `VSHL` instruction must be unconditional. ARM strongly recommends that a Thumb `VSHL` instruction is unconditional, see *Conditional execution* on page A8-288.

`<type>` The data type for the elements of the vectors. It must be one of:

- `S` Signed, encoded as U = 0.
- `U` Unsigned, encoded as U = 1.

Together with the `<size>` field, this indicates the data type and size of the first operand and the result.

`<size>` The data size for the elements of the vectors. It must be one of:

- `8` Encoded as size = `0b00`.
- `16` Encoded as size = `0b01`.
- `32` Encoded as size = `0b10`.
- `64` Encoded as size = `0b11`.

`<Qd>, <Qm>, <Qn>` The destination vector and the operand vectors, for a quadword operation.

`<Dd>, <Dm>, <Dn>` The destination vector and the operand vectors, for a doubleword operation.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        for e = 0 to elements-1
            shift = SInt(Elem[D[n+r],e,esize]<7:0>);
            result = Int(Elem[D[m+r],e,esize], unsigned) << shift;
            Elem[D[d+r],e,esize] = result<esize-1:0>;
```

Exceptions

Undefined Instruction, Hyp Trap.

A8.8.397 VSHLL

Vector Shift Left Long takes each element in a doubleword vector, left shifts them by an immediate value, and places the results in a quadword vector.

The operand elements can be:

- 8-bit, 16-bit, or 32-bit signed integers
- 8-bit, 16-bit, or 32-bit unsigned integers
- 8-bit, 16-bit, or 32-bit untyped integers (maximum shift only).

The result elements are twice the length of the operand elements.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page B1-1232 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see *Conditional execution* on page A8-288.

Encoding T1/A1 Advanced SIMD

d = UInt(D:Vd);  m = UInt(M:Vm);
```

Related encodings See *One register and a modified immediate value* on page A7-269.

Assembler syntax

```
VSHLL{<c>}{<q>}.<type><size>  <Qd>, <Dm>, #<imm>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287. An ARM `VSHLL` instruction must be unconditional. ARM strongly recommends that a Thumb `VSHLL` instruction is unconditional, see *Conditional execution* on page A8-288.

`<type>` The data type for the elements of the operand. It must be one of:

- `S` Signed. In encoding T1/A1, encoded as U = 0.
- `U` Unsigned. In encoding T1/A1, encoded as U = 1.
- `I` Untyped integer, Available only in encoding T2/A2.

`<size>` The data size for the elements of the operand. Table A8-8 shows the permitted values and their encodings:

Table A8-8 VSHLL <size> field encoding

<size>	Encoding T1/A1	Encoding T2/A2
8	Encoded as imm6<5:3> = 0b001	Encoded as size = 0b00
16	Encoded as imm6<5:4> = 0b01	Encoded as size = 0b01
32	Encoded as imm6<5> = 1	Encoded as size = 0b10

`<Qd>, <Dm>` The destination vector and the operand vector.

`<imm>` The immediate value. `<imm>` must lie in the range 1 to `<size>`, and:

- if `<size>` == `<imm>`, the encoding is T2/A2
- otherwise, the encoding is T1/A1, and:
  - if `<size>` == 8, `<imm>` is encoded in imm6<2:0>
  - if `<size>` == 16, `<imm>` is encoded in imm6<3:0>
  - if `<size>` == 32, `<imm>` is encoded in imm6<4:0>.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for e = 0 to elements-1
        result = Int(Elem[Din[m],e,esize], unsigned) << shift_amount;
        Elem[Q[d>>1],e,2*esize] = result<2*esize-1:0>;
```

Exceptions

Undefined Instruction, Hyp Trap.

A8.8.398 VSHR

Vector Shift Right takes each element in a vector, right shifts them by an immediate value, and places the truncated results in the destination vector. For rounded results, see *VRSHR* on page A8-1034.

The operand and result elements must be the same size, and can be any one of:

- 8-bit, 16-bit, 32-bit, or 64-bit signed integers.
- 8-bit, 16-bit, 32-bit, or 64-bit unsigned integers.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page B1-1232 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see *Conditional execution* on page A8-288.

    when "1xxxxx"  esize = 32;  elements = 2;  shift_amount = 64 - UInt(imm6);
d = UInt(D:Vd);  m = UInt(M:Vm);
```

Related encodings See *One register and a modified immediate value* on page A7-269.

Assembler syntax

```
VSHRN{<c>}{<q>}.I<size>  <Dd>, <Qm>, #<imm>
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287. An ARM `VSHRN` instruction must be unconditional. ARM strongly recommends that a Thumb `VSHRN` instruction is unconditional, see *Conditional execution* on page A8-288.

`<size>` The data size for the elements of the vectors. It must be one of:

- `16` Encoded as imm6<5:3> = `0b001`. (8 – `<imm>`) is encoded in imm6<2:0>.
- `32` Encoded as imm6<5:4> = `0b01`. (16 – `<imm>`) is encoded in imm6<3:0>.
- `64` Encoded as imm6<5> = `0b1`. (32 – `<imm>`) is encoded in imm6<4:0>.

`<Dd>, <Qm>` The destination vector, and the operand vector.

`<imm>` The immediate value, in the range 1 to `<size>`/2. See the description of `<size>` for how `<imm>` is encoded.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for e = 0 to elements-1
        result = LSR(Elem[Qin[m>>1],e,2*esize], shift_amount);
        Elem[D[d],e,esize] = result<esize-1:0>;
```

Exceptions

Undefined Instruction, Hyp Trap.

Pseudo-instructions

`VSHRN.I<size>  <Dd>, <Qm>, #0` is a synonym for `VMOVN.I<size> <Dd>, <Qm>`

For details see *VMOVN* on page A8-952.

A8.8.400 VSLI

Vector Shift Left and Insert takes each element in the operand vector, left shifts them by an immediate value, and inserts the results in the destination vector. Bits shifted out of the left of each element are lost.

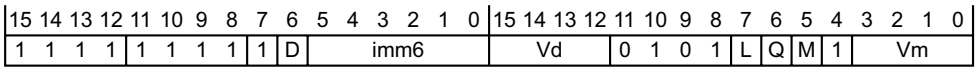
The elements must all be the same size, and can be 8-bit, 16-bit, 32-bit, or 64-bit. There is no distinction between data types.

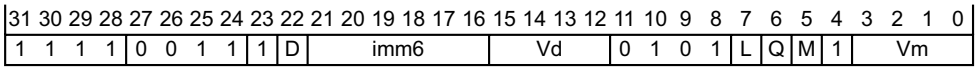
Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page B1-1232 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see *Conditional execution* on page A8-288.

Encoding T1/A1 Advanced SIMD

```
VSLI<c>.<size> <Qd>, <Qm>, #<imm>
VSLI<c>.<size> <Dd>, <Dm>, #<imm>
```





```
if (L:imm6) IN "0000xxx" then SEE "Related encodings";
if Q == '1' && (Vd<0> == '1' || Vm<0> == '1') then UNDEFINED;
case L:imm6 of
    when "0001xxx"  esize = 8;  elements = 8;  shift_amount = UInt(imm6) - 8;
    when "001xxxx"  esize = 16;  elements = 4;  shift_amount = UInt(imm6) - 16;
    when "01xxxxx"  esize = 32;  elements = 2;  shift_amount = UInt(imm6) - 32;
    when "1xxxxxx"  esize = 64;  elements = 1;  shift_amount = UInt(imm6);
d = UInt(D:Vd);  m = UInt(M:Vm);  regs = if Q == '0' then 1 else 2;
```

Related encodings See *One register and a modified immediate value* on page A7-269.

Assembler syntax

`VSLI{<c>}{<q>}.<size>  {<Qd>,} <Qm>, #<imm>`	Encoded as Q = 1
`VSLI{<c>}{<q>}.<size>  {<Dd>,} <Dm>, #<imm>`	Encoded as Q = 0

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287. An ARM `VSLI` instruction must be unconditional. ARM strongly recommends that a Thumb `VSLI` instruction is unconditional, see *Conditional execution* on page A8-288.

`<size>` The data size for the elements of the vectors. It must be one of:

- `8` Encoded as L = 0, imm6<5:3> = `0b001`. `<imm>` is encoded in imm6<2:0>.
- `16` Encoded as L = 0, imm6<5:4> = `0b01`. `<imm>` is encoded in imm6<3:0>.
- `32` Encoded as L = 0, imm6<5> = `0b1`. `<imm>` is encoded in imm6<4:0>.
- `64` Encoded as L = 1. `<imm>` is encoded in imm6<5:0>.

`<Qd>, <Qm>` The destination vector, and the operand vector, for a quadword operation.

`<Dd>, <Dm>` The destination vector, and the operand vector, for a doubleword operation.

`<imm>` The immediate value, in the range 0 to `<size>`-1. See the description of `<size>` for how `<imm>` is encoded.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    mask = LSL(Ones(esize), shift_amount);
    for r = 0 to regs-1
        for e = 0 to elements-1
            shifted_op = LSL(Elem[D[m+r],e,esize], shift_amount);
            Elem[D[d+r],e,esize] = (Elem[D[d+r],e,esize] AND NOT(mask)) OR shifted_op;
```

Exceptions

Undefined Instruction, Hyp Trap.

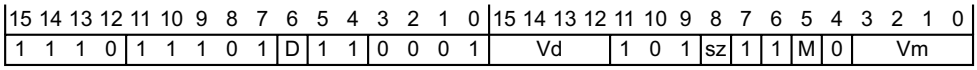
A8.8.401 VSQRT

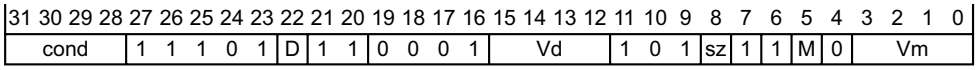
This instruction calculates the square root of the value in a floating-point register and writes the result to another floating-point register.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of general controls of CP10 and CP11 functionality* on page B1-1230 summarizes these controls.

Encoding T1/A1 VFPv2, VFPv3, VFPv4 (sz = 1 UNDEFINED in single-precision only variants)

```
VSQRT<c>.F64 <Dd>, <Dm>
VSQRT<c>.F32 <Sd>, <Sm>
```





```
if FPSCR.Len != '000' || FPSCR.Stride != '00' then SEE "VFP vectors";
dp_operation = (sz == '1');
d = if dp_operation then UInt(D:Vd) else UInt(Vd:D);
m = if dp_operation then UInt(M:Vm) else UInt(Vm:M);
```

VFP vectors This instruction can operate on VFP vectors under control of the FPSCR.{Len, Stride} fields. For details see Appendix K *VFP Vector Operation Support*.

Assembler syntax

`VSQRT{<c>}{<q>}.F64  <Dd>, <Dm>`	Encoded as sz = 1
`VSQRT{<c>}{<q>}.F32  <Sd>, <Sm>`	Encoded as sz = 0

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287.

`<Dd>, <Dm>` The destination vector and the operand vector, for a double-precision operation.

`<Sd>, <Sm>` The destination vector and the operand vector, for a single-precision operation.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckVFPEnabled(TRUE);
    if dp_operation then
        D[d] = FPSqrt(D[m]);
    else
        S[d] = FPSqrt(S[m]);
```

Exceptions

Undefined Instruction, Hyp Trap.

Floating-point exceptions

Invalid Operation, Inexact, Input Denormal.

A8.8.402 VSRA

Vector Shift Right and Accumulate takes each element in a vector, right shifts them by an immediate value, and accumulates the truncated results into the destination vector. (For rounded results, see *VRSRA* on page A8-1042.)

The operand and result elements must all be the same type, and can be any one of:

- 8-bit, 16-bit, 32-bit, or 64-bit signed integers.
- 8-bit, 16-bit, 32-bit, or 64-bit unsigned integers.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page B1-1232 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see *Conditional execution* on page A8-288.

```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287. An ARM `VSRA` instruction must be unconditional. ARM strongly recommends that a Thumb `VSRA` instruction is unconditional, see *Conditional execution* on page A8-288.

`<type>` The data type for the elements of the vectors. It must be one of:

- `S` Signed, encoded as U = 0.
- `U` Unsigned, encoded as U = 1.

`<size>` The data size for the elements of the vectors. It must be one of:

- `8` Encoded as L = 0, imm6<5:3> = `0b001`. (8 – `<imm>`) is encoded in imm6<2:0>.
- `16` Encoded as L = 0, imm6<5:4> = `0b01`. (16 – `<imm>`) is encoded in imm6<3:0>.
- `32` Encoded as L = 0, imm6<5> = `0b1`. (32 – `<imm>`) is encoded in imm6<4:0>.
- `64` Encoded as L = 1. (64 – `<imm>`) is encoded in imm6<5:0>.

`<Qd>, <Qm>` The destination vector, and the operand vector, for a quadword operation.

`<Dd>, <Dm>` The destination vector, and the operand vector, for a doubleword operation.

`<imm>` The immediate value, in the range 1 to `<size>`. See the description of `<size>` for how `<imm>` is encoded.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        for e = 0 to elements-1
            result = Int(Elem[D[m+r],e,esize], unsigned) >> shift_amount;
            Elem[D[d+r],e,esize] = Elem[D[d+r],e,esize] + result;
```

Exceptions

Undefined Instruction, Hyp Trap.

A8.8.403 VSRI

Vector Shift Right and Insert takes each element in the operand vector, right shifts them by an immediate value, and inserts the results in the destination vector. Bits shifted out of the right of each element are lost.

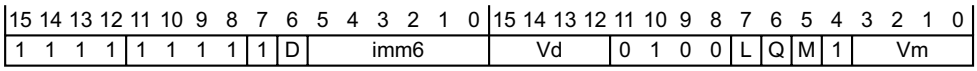
The elements must all be the same size, and can be 8-bit, 16-bit, 32-bit, or 64-bit. There is no distinction between data types.

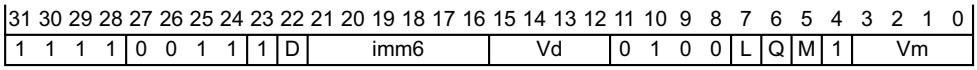
Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page B1-1232 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see *Conditional execution* on page A8-288.

Encoding T1/A1 Advanced SIMD

```
VSRI<c>.<size> <Qd>, <Qm>, #<imm>
VSRI<c>.<size> <Dd>, <Dm>, #<imm>
```





```
if (L:imm6) IN "0000xxx" then SEE "Related encodings";

case L:imm6 of
    when "0001xxx"  esize = 8;  elements = 8;  shift_amount = 16 - UInt(imm6);
    when "001xxxx"  esize = 16;  elements = 4;  shift_amount = 32 - UInt(imm6);
    when "01xxxxx"  esize = 32;  elements = 2;  shift_amount = 64 - UInt(imm6);
    when "1xxxxxx"  esize = 64;  elements = 1;  shift_amount = 64 - UInt(imm6);
d = UInt(D:Vd);  m = UInt(M:Vm);  regs = if Q == '0' then 1 else 2;
```

Related encodings See *One register and a modified immediate value* on page A7-269.

Assembler syntax

`VSRI{<c>}{<q>}.<size>  {<Qd>,} <Qm>, #<imm>`	Encoded as Q = 1
`VSRI{<c>}{<q>}.<size>  {<Dd>,} <Dm>, #<imm>`	Encoded as Q = 0

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287. An ARM `VSRI` instruction must be unconditional. ARM strongly recommends that a Thumb `VSRI` instruction is unconditional, see *Conditional execution* on page A8-288.

`<size>` The data size for the elements of the vectors. It must be one of:

- `8` Encoded as L = 0, imm6<5:3> = `0b001`. (8 – `<imm>`) is encoded in imm6<2:0>.
- `16` Encoded as L = 0, imm6<5:4> = `0b01`. (16 – `<imm>`) is encoded in imm6<3:0>.
- `32` Encoded as L = 0, imm6<5> = `0b1`. (32 – `<imm>`) is encoded in imm6<4:0>.
- `64` Encoded as L = 1. (64 – `<imm>`) is encoded in imm6<5:0>.

`<Qd>, <Qm>` The destination vector, and the operand vector, for a quadword operation.

`<Dd>, <Dm>` The destination vector, and the operand vector, for a doubleword operation.

`<imm>` The immediate value, in the range 1 to `<size>`. See the description of `<size>` for how `<imm>` is encoded.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    mask = LSR(Ones(esize), shift_amount);
    for r = 0 to regs-1
        for e = 0 to elements-1
            shifted_op = LSR(Elem[D[m+r],e,esize], shift_amount);
            Elem[D[d+r],e,esize] = (Elem[D[d+r],e,esize] AND NOT(mask)) OR shifted_op;
```

Exceptions

Undefined Instruction, Hyp Trap.

A8.8.404 VST1 (multiple single elements)

Vector Store (multiple single elements) stores elements to memory from one, two, three, or four registers, without interleaving. Every element of each register is stored. For details of the addressing mode see *Advanced SIMD addressing mode* on page A7-277.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page B1-1232 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see *Conditional execution* on page A8-288.

Encoding T1/A1 Advanced SIMD

`<list>` The registers containing the structure. Encoded with D:Vd = `<Dd>`. It must be one of:

- `{<Dd[x]>, <Dd+1[x]>}` Single-spaced registers, see Table A8-10 on page A8-1071.
- `{<Dd[x]>, <Dd+2[x]>}` Double-spaced registers, see Table A8-10 on page A8-1071. This is not available if `<size>` == 8.

<Rn> Contains the base address for the access.

<align> The alignment. It can be one of:

16 2-byte alignment, available only if <size> is 8

32 4-byte alignment, available only if <size> is 16

64 8-byte alignment, available only if <size> is 32

omitted Standard alignment, see *Unaligned data access* on page A3-108.

: is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see *Advanced SIMD addressing mode* on page A7-277.

! If present, specifies writeback.

<Rm> Contains an address offset applied after the access.

For more information about <Rn>, !, and <Rm>, see *Advanced SIMD addressing mode* on page A7-277.

Table A8-10 Encoding of index, alignment, and register spacing

	<size> == 8	<size> == 16	<size> == 32
Index	index_align[3:1] = x	index_align[3:2] = x	index_align[3] = x
Single-spacing	-	index_align[1] = 0	index_align[2] = 0
Double-spacing	-	index_align[1] = 1	index_align[2] = 1
<align> omitted	index_align[0] = 0	index_align[0] = 0	index_align[1:0] = '00'
<align> == 16	index_align[0] = 1	-	-
<align> == 32	-	index_align[0] = 1	-
<align> == 64	-	-	index_align[1:0] = '01'

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();  NullCheckIfThumbEE(n);
    address = R[n];  if (address MOD alignment) != 0 then GenerateAlignmentException();
    if wback then R[n] = R[n] + (if register_index then R[m] else 2*ebytes);
    MemU[address,ebytes] = Elem[D[d],index,esize];
    MemU[address+ebytes,ebytes] = Elem[D[d2],index,esize];
```

Exceptions

Undefined Instruction, Hyp Trap, Data Abort.

A8.8.408 VST3 (multiple 3-element structures)

This instruction stores multiple 3-element structures to memory from three registers, with interleaving. For more information, see *Element and structure load/store instructions* on page A4-181. Every element of each register is saved. For details of the addressing mode see *Advanced SIMD addressing mode* on page A7-277.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page B1-1232 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see *Conditional execution* on page A8-288.

Assembler syntax

`VST3{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]`	Encoded as Rm = `0b1111`
`VST3{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]!`	Encoded as Rm = `0b1101`
`VST3{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}], <Rm>`	Rm cannot be `0b11x1`

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287. An ARM `VST3` instruction must be unconditional. ARM strongly recommends that a Thumb `VST3` instruction is unconditional, see *Conditional execution* on page A8-288.

`<size>` The data size. It must be one of:

- `8` Encoded as size = `0b00`.
- `16` Encoded as size = `0b01`.
- `32` Encoded as size = `0b10`.

`<list>` The list of registers to store. It must be one of:

- `{<Dd>, <Dd+1>, <Dd+2>}` Encoded as D:Vd = `<Dd>`, type = `0b0100`.
- `{<Dd>, <Dd+2>, <Dd+4>}` Encoded as D:Vd = `<Dd>`, type = `0b0101`.

`<Rn>` Contains the base address for the access.

`<align>` The alignment. It can be:

- `64` 8-byte alignment, encoded as align = `0b01`.
- **omitted** Standard alignment, see *Unaligned data access* on page A3-108. Encoded as align = `0b00`.

: is the preferred separator before the `<align>` value, but the alignment can be specified as `@<align>`, see *Advanced SIMD addressing mode* on page A7-277.

`!` If present, specifies writeback.

`<Rm>` Contains an address offset applied after the access.

For more information about `<Rn>`, `!`, and `<Rm>`, see *Advanced SIMD addressing mode* on page A7-277.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();  NullCheckIfThumbEE(n);
    address = R[n];  if (address MOD alignment) != 0 then GenerateAlignmentException();
    if wback then R[n] = R[n] + (if register_index then R[m] else 24);
    for e = 0 to elements-1
        MemU[address,ebytes] = Elem[D[d],e,esize];
        MemU[address+ebytes,ebytes] = Elem[D[d2],e,esize];
        MemU[address+2*ebytes,ebytes] = Elem[D[d3],e,esize];
        address = address + 3*ebytes;
```

Exceptions

Undefined Instruction, Hyp Trap, Data Abort.

A8.8.409 VST3 (single 3-element structure from one lane)

This instruction stores one 3-element structure to memory from corresponding elements of three registers. For details of the addressing mode see *Advanced SIMD addressing mode* on page A7-277.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page B1-1232 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see *Conditional execution* on page A8-288.

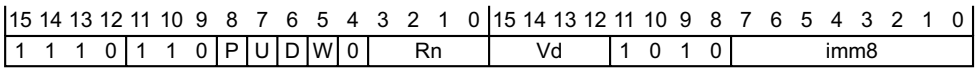
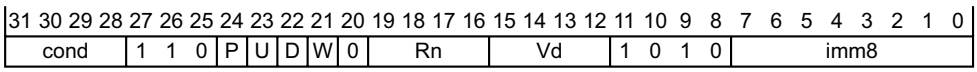
single_regs = FALSE;  add = (U == '1');  wback = (W == '1');
d = UInt(D:Vd);  n = UInt(Rn);  imm32 = ZeroExtend(imm8:'00', 32);
regs = UInt(imm8) DIV 2;  // If UInt(imm8) is odd, see "FSTMX".
if n == 15 && (wback || CurrentInstrSet() != InstrSet_ARM) then UNPREDICTABLE;
if regs == 0 || regs > 16 || (d+regs) > 32 then UNPREDICTABLE;
if VFPSmallRegisterBank() && (d+regs) > 16 then UNPREDICTABLE;
```

Encoding T2/A2 VFPv2, VFPv3, VFPv4

`VSTM{mode}<c> <Rn>{!}, <list>` `<list>` is consecutive 32-bit registers





```
if P == '0' && U == '0' && W == '0' then SEE "Related encodings";
if P == '1' && U == '0' && W == '1' && Rn == '1101' then SEE VPUSH;
if P == '1' && W == '0' then SEE VSTR;
if P == U && W == '1' then UNDEFINED;
// Remaining combinations are PUW = 010 (IA without !), 011 (IA with !), 101 (DB with !)
single_regs = TRUE;  add = (U == '1');  wback = (W == '1');  d = UInt(Vd:D);  n = UInt(Rn);
imm32 = ZeroExtend(imm8:'00', 32);  regs = UInt(imm8);
if n == 15 && (wback || CurrentInstrSet() != InstrSet_ARM) then UNPREDICTABLE;
if regs == 0 || (d+regs) > 32 then UNPREDICTABLE;
```

Related encodings See *64-bit transfers between ARM core and extension registers* on page A7-279.

FSTMX Encoding T1/A1 behaves as described by the pseudocode if imm8 is odd. However, there is no UAL syntax for such encodings and ARM deprecates their use. For more information, see *FLDMX, FSTMX* on page A8-388.

Assembler syntax

```
VSTM{<mode>}{<c>}{<q>}{.<size>}  <Rn>{!}, <list>
```

where:

`<mode>` The addressing mode:

- `IA` Increment After. The consecutive addresses start at the address specified in `<Rn>`. This is the default and can be omitted. Encoded as P = 0, U = 1.
- `DB` Decrement Before. The consecutive addresses end just before the address specified in `<Rn>`. Encoded as P = 1, U = 0.

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287.

`<size>` An optional data size specifier. If present, it must be equal to the size in bits, 32 or 64, of the registers in `<list>`.

`<Rn>` The base register. The SP can be used. In the ARM instruction set, if `!` is not specified the PC can be used. However, ARM deprecates use of the PC.

`!` Causes the instruction to write a modified value back to `<Rn>`. Required if <mode> == `DB`. Encoded as W = 1.

If `!` is omitted, the instruction does not change `<Rn>` in this way. Encoded as W = 0.

`<list>` The extension registers to be stored, as a list of consecutively numbered doubleword (encoding T1/A1) or singleword (encoding T2/A2) registers, separated by commas and surrounded by brackets. It is encoded in the instruction by setting D and Vd to specify the first register in the list, and imm8 to twice the number of registers in the list (encoding T1/A1) or the number of registers (encoding T2/A2). `<list>` must contain at least one register. If it contains doubleword registers it must not contain more than 16 registers.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckVFPEnabled(TRUE);  NullCheckIfThumbEE(n);
    address = if add then R[n] else R[n]-imm32;
    if wback then R[n] = if add then R[n]+imm32 else R[n]-imm32;
    for r = 0 to regs-1
        if single_regs then
            MemA[address,4] = S[d+r];  address = address+4;
        else
            // Store as two word-aligned words in the correct order for current endianness.
            MemA[address,4] = if BigEndian() then D[d+r]<63:32> else D[d+r]<31:0>;
            MemA[address+4,4] = if BigEndian() then D[d+r]<31:0> else D[d+r]<63:32>;
            address = address+8;
```

Exceptions

Undefined Instruction, Hyp Trap, Data Abort.

A8.8.413 VSTR

This instruction stores a single extension register to memory, using an address from an ARM core register, with an optional offset.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of general controls of CP10 and CP11 functionality* on page B1-1230 and *Summary of access controls for Advanced SIMD functionality* on page B1-1232 summarize these controls.

Encoding T1/A1 VFPv2, VFPv3, VFPv4, Advanced SIMD

Assembler syntax

```
VSTR{<c>}{<q>}{.64}  <Dd>, [<Rn>{, #+/-<imm>}]          Encoding T1/A1
VSTR{<c>}{<q>}{.32}  <Sd>, [<Rn>{, #+/-<imm>}]          Encoding T2/A2
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287.

`.32, .64` Optional data size specifiers.

`<Dd>` The source register for a doubleword store.

`<Sd>` The source register for a singleword store.

`<Rn>` The base register. The SP can be used. In the ARM instruction set the PC can be used. However, ARM deprecates use of the PC.

`+/-` Is + or omitted if the immediate offset is to be added to the base register value (`add == TRUE`), or – if it is to be subtracted (`add == FALSE`). `#0` and `#-0` generate different instructions.

`<imm>` The immediate offset used for forming the address. Values are multiples of 4 in the range 0-1020. `<imm>` can be omitted, meaning an offset of +0.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckVFPEnabled(TRUE);  NullCheckIfThumbEE(n);
    address = if add then (R[n] + imm32) else (R[n] - imm32);
    if single_reg then
        MemA[address,4] = S[d];
    else
        // Store as two word-aligned words in the correct order for current endianness.
        MemA[address,4] = if BigEndian() then D[d]<63:32> else D[d]<31:0>;
        MemA[address+4,4] = if BigEndian() then D[d]<31:0> else D[d]<63:32>;
```

Exceptions

Undefined Instruction, Hyp Trap, Data Abort.

A8.8.414 VSUB (integer)

Vector Subtract subtracts the elements of one vector from the corresponding elements of another vector, and places the results in the destination vector.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page B1-1232 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see *Conditional execution* on page A8-288.

```

Assembler syntax

`VSWP{<c>}{<q>}{.<dt>}  <Qd>, <Qm>`	Encoded as Q = 1, size = `0b00`
`VSWP{<c>}{<q>}{.<dt>}  <Dd>, <Dm>`	Encoded as Q = 0, size = `0b00`

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287. An ARM `VSWP` instruction must be unconditional. ARM strongly recommends that a Thumb `VSWP` instruction is unconditional, see *Conditional execution* on page A8-288.

`<dt>` An optional data type. It is ignored by assemblers, and does not affect the encoding.

`<Qd>, <Qm>` The vectors for a quadword operation.

`<Dd>, <Dm>` The vectors for a doubleword operation.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        if d == m then
            D[d+r] = bits(64) UNKNOWN;
        else
            D[d+r] = Din[m+r];
            D[m+r] = Din[d+r];
```

Exceptions

Undefined Instruction, Hyp Trap.

A8.8.419 VTBL, VTBX

Vector Table Lookup uses byte indexes in a control vector to look up byte values in a table and generate a new vector. Indexes out of range return 0.

Vector Table Extension works in the same way, except that indexes out of range leave the destination element unchanged.

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page B1-1232 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see *Conditional execution* on page A8-288.

Encoding T1/A1 Advanced SIMD

```
V<op><c>.8 <Dd>, <list>, <Dm>
```

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

if n+length > 32 then UNPREDICTABLE;
```

Assembler syntax

```
V<op>{<c>}{<q>}.8  <Dd>, <list>, <Dm>
```

where:

<op> The operation. It must be one of:

- TBL Vector Table Lookup. Encoded as op = 0.
- TBX Vector Table Extension. Encoded as op = 1.

<c>, <q> See *Standard assembler syntax fields* on page A8-287. An ARM VTBL or VTBX instruction must be unconditional. ARM strongly recommends that a Thumb VTBL or VTBX instruction is unconditional, see *Conditional execution* on page A8-288.

<Dd> The destination vector.

<list> The vectors containing the table. It must be one of:

- {<Dn>} encoded as len = 0b00.
- {<Dn>, <Dn+1>} encoded as len = 0b01.
- {<Dn>, <Dn+1>, <Dn+2>} encoded as len = 0b10.
- {<Dn>, <Dn+1>, <Dn+2>, <Dn+3>} encoded as len = 0b11.

<Dm> The index vector.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();

    // Create 256-bit = 32-byte table variable, with zeros in entries that will not be used.
    table3 = if length == 4 then D[n+3] else Zeros(64);
    table2 = if length >= 3 then D[n+2] else Zeros(64);
    table1 = if length >= 2 then D[n+1] else Zeros(64);
    table = table3 : table2 : table1 : D[n];

    for i = 0 to 7
        index = UInt(Elem[D[m],i,8]);
        if index < 8*length then
            Elem[D[d],i,8] = Elem[table,index,8];
        else
            if is_vtbl then
                Elem[D[d],i,8] = Zeros(8);
            // else Elem[D[d],i,8] unchanged
```

Exceptions

Undefined Instruction, Hyp Trap.

A8.8.420 VTRN

Vector Transpose treats the elements of its operand vectors as elements of 2 × 2 matrices, and transposes the matrices.

The elements of the vectors can be 8-bit, 16-bit, or 32-bit. There is no distinction between data types.

Figure A8-7 shows the operation of doubleword VTRN. Quadword VTRN performs the same operation as doubleword VTRN twice, once on the upper halves of the quadword vectors, and once on the lower halves

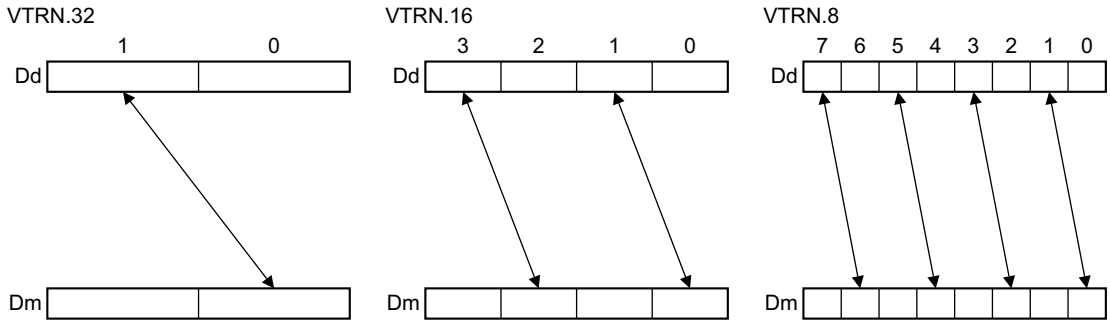

Figure A8-7 VTRN doubleword operation

Depending on settings in the CPACR, NSACR, and HCPTR registers, and the security state and mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. *Summary of access controls for Advanced SIMD functionality* on page B1-1232 summarizes these controls.

ARM deprecates the conditional execution of any Advanced SIMD instruction encoding that is not also available as a VFP instruction encoding, see *Conditional execution* on page A8-288.

Encoding T1/A1 Advanced SIMD

Pseudo-instructions

`VZIP.32 <Dd>, <Dm>` is a synonym for `VTRN.32 <Dd>, <Dm>`. For details see *VTRN* on page A8-1096.

A8.8.424 WFE

Wait For Event is a hint instruction that permits the processor to enter a low-power state until one of a number of events occurs, including events signaled by executing the SEV instruction on any processor in the multiprocessor system. For more information, see *Wait For Event and Send Event* on page B1-1199.

In an implementation that includes the Virtualization Extensions, if HCR.TWE is set to 1, execution of a WFE instruction in a Non-secure mode other than Hyp mode generates a Hyp Trap exception if, ignoring the value of the HCR.TWE bit, conditions permit the processor to suspend execution. For more information see *Trapping use of the WFI and WFE instructions* on page B1-1255.

Encoding T1 ARMv7 (executes as NOP in ARMv6T2)

```

Exceptions

Hyp Trap.

A8.8.425 WFI

Wait For Interrupt is a hint instruction that permits the processor to enter a low-power state until one of a number of asynchronous events occurs. For more information, see *Wait For Interrupt* on page B1-1202.

In an implementation that includes the Virtualization Extensions, if HCR.TWI is set to 1, execution of a `WFI` instruction in a Non-secure mode other than Hyp mode generates a Hyp Trap exception if, ignoring the value of the HCR.TWI bit, conditions permit the processor to suspend execution. For more information see *Trapping use of the WFI and WFE instructions* on page B1-1255.

A8.8.426 YIELD

YIELD is a hint instruction. Software with a multithreading capability can use a YIELD instruction to indicate to the hardware that it is performing a task, for example a spin-lock, that could be swapped out to improve overall system performance. Hardware can use this hint to suspend and resume multiple software threads if it supports the capability.

For more information about the recommended use of this instruction see *The Yield instruction* on page A4-178.

Chapter A9
The ThumbEE Instruction Set

This chapter describes the ThumbEE instruction set. It contains the following sections:

- *About the ThumbEE instruction set* on page A9-1112
- *ThumbEE instruction set encoding* on page A9-1115
- *Additional instructions in Thumb and ThumbEE instruction sets* on page A9-1116
- *ThumbEE instructions with modified behavior* on page A9-1117
- *Additional ThumbEE instructions* on page A9-1123.

A9.1 About the ThumbEE instruction set

In general, instructions in ThumbEE are identical to Thumb instructions, with the following exceptions:

- A small number of instructions are affected by modifications to transitions from ThumbEE state. For more information, see *ThumbEE state transitions*.
- A substantial number of instructions have a null check on the base register before any other operation takes place, but are identical (or almost identical) in all other respects. For more information, see *Null checking* on page A9-1113.
- A small number of instructions are modified in additional ways. See *Instructions with modifications* on page A9-1113.
- Three Thumb instructions, `BLX` (immediate), 16-bit `LDM`, and 16-bit `STM`, are removed in ThumbEE state.

  The encoding corresponding to `BLX` (immediate) in Thumb is UNDEFINED in ThumbEE state.

  16-bit `LDM` and `STM` are replaced by new instructions, for details see *Additional ThumbEE instructions* on page A9-1123.
- Two new 32-bit instructions, `ENTERX` and `LEAVEX`, are introduced in both the Thumb instruction set and the ThumbEE instruction set. See *Additional instructions in Thumb and ThumbEE instruction sets* on page A9-1116. These instructions use previously UNDEFINED encodings.

Attempting to execute ThumbEE instructions at PL2 is UNPREDICTABLE.

From the publication of issue C.a of this manual, ARM deprecates any use of the ThumbEE instruction set.

A9.1.1 ThumbEE state transitions

Instruction set state transitions to ThumbEE state can occur implicitly as part of a return from exception, or explicitly on execution of an `ENTERX` instruction.

Instruction set state transitions from ThumbEE state can only occur due to an exception, or due to a transition to Thumb state using the `LEAVEX` instruction. Return from exception instructions (`RFE` and `SUBS PC, LR, #imm`) are UNPREDICTABLE in ThumbEE state.

Any other Thumb instructions that can update the PC in ThumbEE state are UNPREDICTABLE if they attempt to change to ARM state. Interworking of ARM and Thumb instructions is not supported in ThumbEE state. The instructions affected are:

- `LDR`, `LDM`, and `POP` instructions that write to the PC, if bit[0] of the value loaded to the PC is 0
- `BLX` (register), `BX`, and `BXJ`, where `Rm` bit[0] == 0.

Note

`SVC`, `BKPT`, and UNDEFINED instructions cause an exception to occur.

If a `BXJ <Rm>` instruction is executed in ThumbEE state, with Rm bit[0] == 1, it does not enter Jazelle state. Instead, it behaves like the corresponding `BX <Rm>` instruction and remains in ThumbEE state.

Debug state is a special case. For the rules governing changes to CPSR state bits and Debug state, see *Executing instructions in Debug state* on page C5-2096.

A9.1.2 Null checking

A *null check* is performed for all load/store instructions when they are executed in ThumbEE state. If the value in the base register is zero, execution branches to the NullCheck handler at HandlerBase – 4.

For most load/store instructions, this is the only difference from normal Thumb operation. Exceptions to this rule are described in this chapter.

Note

- The null check examines the value in the base register, not any calculated value offset from the base register.
- If the base register is the SP or the PC, a zero value in the base register results in UNPREDICTABLE behavior.
- RFE and SRS instructions do not require null checking because they have UNPREDICTABLE behavior when executed in ThumbEE state.

The instructions affected by null checking are:

- all instructions whose mnemonic starts with LD, ST, VLD or VST
- POP, PUSH, TBB, TBH, VPOP, and VPUSH.

For each of these instructions, the pseudocode shown in the Operation section uses the following function:

```
// NullCheckIfThumbEE()
// ====================

NullCheckIfThumbEE(integer n)
    if CurrentInstrSet() == InstrSet_ThumbEE then
        if n == 15 then
            if IsZero(Align(PC,4)) then UNPREDICTABLE;
        elsif n == 13 then
            if IsZero(SP) then UNPREDICTABLE;
        else
            if IsZero(R[n]) then
                LR = PC<31:1> : '1';  // PC holds this instruction's address plus 4
                ITSTATE.IT = '00000000';
                BranchWritePC(TEEHBR - 4);
                EndOfInstruction();
    return;
```

A9.1.3 Instructions with modifications

In addition to the instructions described in *ThumbEE state transitions* on page A9-1112 and *Null checking*, Table A9-1 shows other instructions that are modified in ThumbEE state. The pseudocode, including the null check if any, is given in *ThumbEE instructions with modified behavior* on page A9-1117.

Table A9-1 Modified instructions

Instructions	Rbase	Modification
LDR (register)	Rn	Rm multiplied by 4, null check
LDRH (register)	Rn	Rm multiplied by 2, null check
LDRSH (register)	Rn	Rm multiplied by 2, null check
STR (register)	Rn	Rm multiplied by 4, null check
STRH (register)	Rn	Rm multiplied by 2, null check

A9.1.4 IT block and check handlers

CHKA, stores, and loads can occur anywhere in an IT block, except that a load to the PC is permitted only as the last instruction in the block. If one of these instructions results in a branch to the null pointer or array index handlers, the IT state bits in ITSTATE are cleared. This provides unconditional execution from the start of the handler.

The original IT state bits are not preserved.

A9.2 ThumbEE instruction set encoding

In general, instructions in the ThumbEE instruction set are encoded in exactly the same way as Thumb instructions described in Chapter A6 *Thumb Instruction Set Encoding*. The differences are as follows:

- There are no 16-bit `LDM` or `STM` instructions in the ThumbEE instruction set.
- The 16-bit encodings used for `LDM` and `STM` in the Thumb instruction set are used for different 16-bit instructions in the ThumbEE instruction set. For details, see *16-bit ThumbEE instructions*.
- There are two new 32-bit instructions in both Thumb state and ThumbEE state. For details, see *Additional instructions in Thumb and ThumbEE instruction sets* on page A9-1116.

A9.2.1 16-bit ThumbEE instructions

The encoding of 16-bit ThumbEE instructions is:

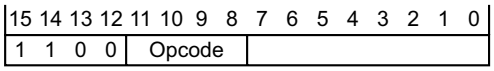

Table A9-2 shows the allocation of encodings in this space.

Table A9-2 16-bit ThumbEE instructions

Opcode	Instruction	See
0000	Handler Branch with Parameter	*HBP* on page A9-1127
0001	UNDEFINED	-
001x	Handler Branch, Handler Branch with Link	*HB, HBL* on page A9-1125
01xx	Handler Branch with Link and Parameter	*HBLP* on page A9-1126
100x	Load Register from a frame	*LDR (immediate)* on page A9-1128
1010	Check Array	*CHKA* on page A9-1124
1011	Load Register from a literal pool	*LDR (immediate)* on page A9-1128
110x	Load Register (array operations)	*LDR (immediate)* on page A9-1128
111x	Store Register to a frame	*STR (immediate)* on page A9-1130

A9.3 Additional instructions in Thumb and ThumbEE instruction sets

On a processor with the ThumbEE Extension, there are two additional 32-bit instructions, ENTERX and LEAVEX. These are available in both Thumb state and ThumbEE state.

A9.3.1 ENTERX, LEAVEX

ENTERX causes a change from Thumb state to ThumbEE state, or has no effect in ThumbEE state.

ENTERX is UNDEFINED in Hyp mode.

LEAVEX causes a change from ThumbEE state to Thumb state, or has no effect in Thumb state.

Encoding T1 ThumbEE

ENTERX	Not permitted in IT block.
LEAVEX	Not permitted in IT block.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	0	0	1	1	1	0	1	1	(1)	(1)	(1)	(1)	1	0	(0)	0	(1)	(1)	(1)	(1)	0	0	0	J	(1)	(1)	(1)	(1)

```
is_enterx = (J == '1');
if InITBlock() then UNPREDICTABLE;
```

Assembler syntax

ENTERX{<q>}	Encoded as J = 1
LEAVEX{<q>}	Encoded as J = 0

where:

<q> See *Standard assembler syntax fields* on page A8-287. An ENTERX or LEAVEX instruction must be unconditional.

Operation

```
if is_enterx then
    if CurrentModeIsHyp() then
        UNDEFINED;
    else
        SelectInstrSet(InstrSet_ThumbEE);
else
    SelectInstrSet(InstrSet_Thumb);
```

Exceptions

None.

A9.4 ThumbEE instructions with modified behavior

The 16-bit encodings of the following Thumb instructions have changed functionality in ThumbEE:

- *LDR (register)* on page A9-1118
- *LDRH (register)* on page A9-1119
- *LDRSH (register)* on page A9-1120
- *STR (register)* on page A9-1121
- *STRH (register)* on page A9-1122.

In ThumbEE state there are the following changes in the behavior of instructions:

- All load/store instructions perform null checks on their base register values, as described in *Null checking* on page A9-1113. The pseudocode for these instructions in Chapter A8 *Instruction Details* describes this by calling the `NullCheckIfThumbEE()` pseudocode procedure.
- Instructions that attempt to enter ARM state are UNPREDICTABLE, as described in *ThumbEE state transitions* on page A9-1112. The pseudocode for these instructions in Chapter A8 *Instruction Details* describes this by calling the `SelectInstrSet()` or `BXWritePC()` pseudocode procedure.
- The `BXJ` instruction behaves like the `BX` instruction, as described in *ThumbEE state transitions* on page A9-1112. The pseudocode for the instruction, in *BXJ* on page A8-354, describes this directly.

A9.4.1 LDR (register)

Load Register (register) calculates an address from a base register value and an offset register value, loads a word from memory, and writes it to a register. The offset register value is shifted left by 2 bits. For information about memory accesses see *Memory accesses* on page A8-294.

The similar Thumb instruction does not have a left shift.

Encoding T1 ThumbEE

```
LDR<c> <Rt>, [<Rn>, <, <Rm>, LSL #2]
```

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	0	1	1	0	0	Rm			Rn			Rt		

```
t = UInt(Rt);  n = UInt(Rn);  m = UInt(Rm);
```

Assembler syntax

```
LDR{<c>}{<q>}  <Rt>, [<Rn>, <Rm>, LSL #2]
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287.

`<Rt>` The destination register.

`<Rn>` The base register.

`<Rm>` Contains the offset that is shifted and applied to the value of `<Rn>` to form the address.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  NullCheckIfThumbEE(n);
    address = R[n] + LSL(R[m],2);
    R[t] = MemU[address,4];
```

Exceptions and checks

Data Abort, NullCheck.

A9.4.2 LDRH (register)

Load Register Halfword (register) calculates an address from a base register value and an offset register value, loads a halfword from memory, zero-extends it to form a 32-bit word, and writes it to a register. The offset register value is shifted left by 1 bit. For information about memory accesses see *Memory accesses* on page A8-294.

The similar Thumb instruction does not have a left shift.

Encoding T1 ThumbEE

```
LDRH<c> <Rt>, [<Rn>, <, <Rm>, LSL #1]
```

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	0	1	1	0	1	Rm			Rn			Rt		

```
t = UInt(Rt);  n = UInt(Rn);  m = UInt(Rm);
```

Assembler syntax

```
LDRH{<c>}{<q>}  <Rt>, [<Rn>, <Rm>, LSL #1]
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287.

`<Rt>` The destination register.

`<Rn>` The base register.

`<Rm>` Contains the offset that is shifted and applied to the value of `<Rn>` to form the address.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  NullCheckIfThumbEE(n);
    address = R[n] + LSL(R[m],1);
    R[t] = ZeroExtend(MemU[address,2], 32);
```

Exceptions and checks

Data Abort, NullCheck.

A9.4.3 LDRSH (register)

Load Register Signed Halfword (register) calculates an address from a base register value and an offset register value, loads a halfword from memory, sign-extends it to form a 32-bit word, and writes it to a register. The offset register value is shifted left by 1 bit. For information about memory accesses see *Memory accesses* on page A8-294.

The similar Thumb instruction does not have a left shift.

Encoding T1 ThumbEE

```
LDRSH<c> <Rt>, [<Rn>, <Rm>, LSL #1]
```

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	0	1	1	1	1	Rm			Rn			Rt		

```
t = UInt(Rt);  n = UInt(Rn);  m = UInt(Rm);
```

Assembler syntax

```
LDRSH{<c>}{<q>}  <Rt>, [<Rn>, <Rm>, LSL #1]
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287.

`<Rt>` The destination register.

`<Rn>` The base register.

`<Rm>` Contains the offset that is shifted and applied to the value of `<Rn>` to form the address.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  NullCheckIfThumbEE(n);
    address = R[n] + LSL(R[m],1);
    R[t] = SignExtend(MemU[address,2], 32);
```

Exceptions and checks

Data Abort, NullCheck.

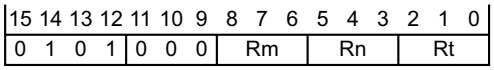
A9.4.4 STR (register)

Store Register (register) calculates an address from a base register value and an offset register value, and stores a word from a register to memory. The offset register value is shifted left by 2 bits. For information about memory accesses see *Memory accesses* on page A8-294.

The similar Thumb instruction does not have a left shift.

Encoding T1 ThumbEE

```
STR<c> <Rt>, [<Rn>, <Rm>, LSL #2]
```



```
t = UInt(Rt);  n = UInt(Rn);  m = UInt(Rm);
```

Assembler syntax

```
STR{<c>}{<q>}  <Rt>, [<Rn>, <Rm>, LSL #2]
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287.

`<Rt>` The source register.

`<Rn>` The base register.

`<Rm>` Contains the offset that is shifted and applied to the value of `<Rn>` to form the address.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  NullCheckIfThumbEE(n);
    address = R[n] + LSL(R[m],2);
    MemU[address,4] = R[t];
```

Exceptions and checks

Data Abort, NullCheck.

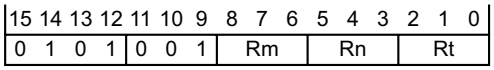
A9.4.5 STRH (register)

Store Register Halfword (register) calculates an address from a base register value and an offset register value, and stores a halfword from a register to memory. The offset register value is shifted left by 1 bit. For information about memory accesses see *Memory accesses* on page A8-294.

The similar Thumb instruction does not have a left shift.

Encoding T1 ThumbEE

```
STRH<c> <Rt>, [<Rn>, <Rm>, LSL #1]
```



```
t = UInt(Rt);  n = UInt(Rn);  m = UInt(Rm);
```

Assembler syntax

```
STRH{<c>}{<q>}  <Rt>, [<Rn>, <Rm>, LSL #1]
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287.

`<Rt>` The source register.

`<Rn>` The base register.

`<Rm>` Contains the offset that is shifted and applied to the value of `<Rn>` to form the address.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  NullCheckIfThumbEE(n);
    address = R[n] + LSL(R[m],1);
    MemU[address,2] = R[t]<15:0>;
```

Exceptions and checks

Data Abort, NullCheck.

A9.5 Additional ThumbEE instructions

The following instructions are available in ThumbEE state, but not in Thumb state:

- *CHKA* on page A9-1124
- *HB, HBL* on page A9-1125
- *HBLP* on page A9-1126
- *HBP* on page A9-1127
- *LDR (immediate)* on page A9-1128
- *STR (immediate)* on page A9-1130.

These are 16-bit instructions. They occupy the instruction encoding space that `STMIA` and `LDMIA` occupy in Thumb state.

A9.5.1 CHKA

CHKA (Check Array) compares the unsigned values in two registers. If the first is lower than, or the same as, the second, it copies the PC to the LR, and causes a branch to the IndexCheck handler.

Encoding E1 ThumbEE

```
CHKA<c> <Rn>, <Rm>
```

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	0	0	1	0	1	0	N	Rm				Rn		

```
n = UInt(N:Rn);  m = UInt(Rm);
if n == 15 || m IN {13,15} then UNPREDICTABLE;
```

Assembler syntax

```
CHKA{<c>}{<q>}  <Rn>, <Rm>
```

where:

<c>, <q> See *Standard assembler syntax fields* on page A8-287.

<Rn> The first operand register. This contains the array size. Use of the SP is permitted.

<Rm> The second operand register. This contains the array index.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if UInt(R[n]) <= UInt(R[m]) then
        LR = PC<31:1> : '1';  // PC holds this instruction's address + 4
        ITSTATE.IT = '00000000';
        BranchWritePC(TEEHBR - 8);
```

Exceptions and checks

IndexCheck.

Usage

Use CHKA to check that an array index is in bounds.

CHKA does not modify the APSR condition flags.

A9.5.2 HB, HBL

Handler Branch branches to a specified handler.

Handler Branch with Link saves a return address to the LR, and then branches to a specified handler.

Encoding E1 ThumbEE

`HB{L}<c> #<HandlerID>` Outside or last in IT block

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	0	0	0	0	1	L	handler							

```
generate_link = (L == '1');  handler_offset = ZeroExtend(handler:'00000', 32);
if InITBlock() && !LastInITBlock() then UNPREDICTABLE;
```

Assembler syntax

`HB{<c>}{<q>}  #<HandlerID>`	Encoded as L = 0
`HBL{<c>}{<q>}  #<HandlerID>`	Encoded as L = 1

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287.

`<HandlerID>` The index number of the handler to be called, in the range 0-255.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if generate_link then
        next_instr_addr = PC - 2;
        LR = next_instr_addr<31:1> : '1';
    BranchWritePC(TEEHBR + handler_offset);
```

Exceptions

None.

Usage

`HB{L}` makes a large number of handlers available.

A9.5.3 HBLP

HBLP (Handler Branch with Link and Parameter) saves a return address to the LR, and then branches to a specified handler. It passes a 5-bit parameter to the handler in R8.

Encoding E1 ThumbEE

HBLP<c> #<imm>, #<HandlerID> Outside or last in IT block

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	0	0	0	1	imm5					handler				

```
imm32 = ZeroExtend(imm5, 32);  handler_offset = ZeroExtend(handler:'00000', 32);
if InITBlock() && !LastInITBlock() then UNPREDICTABLE;
```

Assembler syntax

```
HBLP{<c>}{<q>}  #<imm>, #<HandlerID>
```

where:

<c>, <q> See *Standard assembler syntax fields* on page A8-287.

<imm> The parameter to pass to the handler, in the range 0-31.

<HandlerID> The index number of the handler to be called, in the range 0-31.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    R[8] = imm32;
    next_instr_addr = PC - 2;
    LR = next_instr_addr<31:1> : '1';
    BranchWritePC(TEEHBR + handler_offset);
```

Exceptions

None.

A9.5.4 HBP

HBP (Handler Branch with Parameter) causes a branch to a specified handler. It passes a 3-bit parameter to the handler in R8.

Encoding E1 ThumbEE

HBP<c> #<imm>, #<HandlerID> — Outside or last in IT block

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	0	0	0	0	0	0	imm3			handler				

```
imm32 = ZeroExtend(imm3, 32);  handler_offset = ZeroExtend(handler:'00000', 32);
if InITBlock() && !LastInITBlock() then UNPREDICTABLE;
```

Assembler syntax

```
HBP{<c>}{<q>}  #<imm>, #<HandlerID>
```

where:

<c>, <q> — See *Standard assembler syntax fields* on page A8-287.

<imm> — The parameter to pass to the handler, in the range 0-7.

<HandlerID> — The index number of the handler to be called, in the range 0-31.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    R[8] = imm32;
    BranchWritePC(TEEHBR + handler_offset);
```

Exceptions

None.

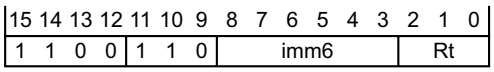
A9.5.5 LDR (immediate)

Load Register (immediate) provides 16-bit instructions to load words using:

- R9 as base register, with a positive offset of up to 63 words, for loading from a frame
- R10 as base register, with a positive offset of up to 31 words, for loading from a literal pool
- R0-R7 as base register, with a negative offset of up to 7 words, for array operations.

Encoding E1 ThumbEE

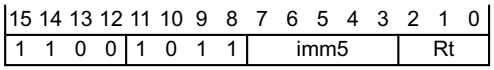
```
LDR<c> <Rt>, [R9{, #<imm>}]
```



```
t = UInt(Rt);  n = 9;  imm32 = ZeroExtend(imm6:'00', 32);  add = TRUE;
```

Encoding E2 ThumbEE

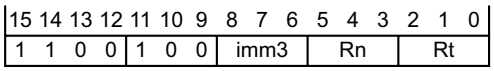
```
LDR<c> <Rt>, [R10{, #<imm>}]
```



```
t = UInt(Rt);  n = 10;  imm32 = ZeroExtend(imm5:'00', 32);  add = TRUE;
```

Encoding E3 ThumbEE

```
LDR<c> <Rt>, [<Rn>{, #-<imm>}]
```



```
t = UInt(Rt);  n = UInt(Rn);  imm32 = ZeroExtend(imm3:'00', 32);  add = FALSE;
```

Assembler syntax

```
LDR{<c>}{<q>}  <Rt>, [<Rn>{, #<imm>}]
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287.

`<Rt>` The destination register.

`<Rn>` The base register. This register is:

- R9 for encoding E1
- R10 for encoding E2
- any of R0-R7 for encoding E3.

`<imm>` The immediate offset used for forming the address. Values are multiples of 4 in the range:

`0-252` encoding E1

`0-124` encoding E2

`-28-0` encoding E3.

`<imm>` can be omitted, meaning an offset of 0.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  NullCheckIfThumbEE(n);
    address = if add then (R[n] + imm32) else (R[n] - imm32);
    R[t] = MemU[address,4];
```

Exceptions and checks

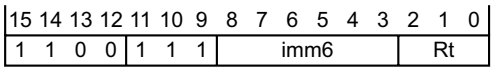
Data Abort, NullCheck.

A9.5.6 STR (immediate)

Store Register (immediate) provides a 16-bit word store instruction using R9 as base register, with a positive offset of up to 63 words, for storing to a frame.

Encoding E1 ThumbEE

```
STR<c> <Rt>, [R9, #<imm>]
```



```
t = UInt(Rt);  imm32 = ZeroExtend(imm6:'00', 32);
```

Assembler syntax

```
STR{<c>}{<q>}  <Rt>, [R9, #<imm>]
```

where:

`<c>, <q>` See *Standard assembler syntax fields* on page A8-287.

`<Rt>` The source register.

`<imm>` The immediate offset applied to the value of R9 to form the address. Values are multiples of 4 in the range 0-252.

`<imm>` can be omitted, meaning an offset of 0.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  NullCheckIfThumbEE(9);
    address = R[9] + imm32;
    MemU[address,4] = R[t];
```

Exceptions and checks

Data Abort, NullCheck.

Part B

System Level Architecture

Chapter B1
The System Level Programmers' Model

This chapter provides a system level view of the programmers' model. It contains the following sections:

- *About the System level programmers' model* on page B1-1134
- *System level concepts and terminology* on page B1-1135
- *ARM processor modes and ARM core registers* on page B1-1139
- *Instruction set states* on page B1-1155
- *The Security Extensions* on page B1-1156
- *The Large Physical Address Extension* on page B1-1159
- *The Virtualization Extensions* on page B1-1161
- *Exception handling* on page B1-1164
- *Exception descriptions* on page B1-1204
- *Coprocessors and system control* on page B1-1225
- *Advanced SIMD and floating-point support* on page B1-1228
- *Thumb Execution Environment* on page B1-1239
- *Jazelle direct bytecode execution* on page B1-1240
- *Traps to the hypervisor* on page B1-1247.

Note

In this chapter, system register names usually link to the description of the register in Chapter B4 *System Control Registers in a VMSA implementation*, for example SCTLR. If the register is included in a PMSA implementation, then it is also described in Chapter B6 *System Control Registers in a PMSA implementation*.

B1.1 About the System level programmers' model

An application programmer has only a restricted view of the system. The System level programmers' model supports this application level view of the system, and includes features required for an operating system (OS) to provide the programming environment seen by an application.

The system level programmers' model includes all of the system features required to support operating systems and to handle hardware events.

System level concepts and terminology on page B1-1135 gives a system level introduction to the basic concepts of the ARM architecture, and the terminology used for describing the architecture. The rest of this chapter describes the system level programmers' model.

The other chapters in this part describe:

- The memory system architectures:
  - Chapter B2 *Common Memory System Architecture Features* describes common features of the memory system architectures
  - Chapter B3 *Virtual Memory System Architecture (VMSA)* describes the *Virtual Memory System Architecture* (VMSA) used in the ARMv7-A profile
  - Chapter B5 *Protected Memory System Architecture (PMSA)* describes the *Protected Memory System Architecture* (PMSA) used in the ARMv7-R profile.
- The CPUID mechanism, that an OS can use to determine the capabilities of the processor it is running on. See Chapter B7 *The CPUID Identification Scheme*.
- The instructions that provide system level functionality, such as returning from an exception. See Chapter B9 *System Instructions*.

B1.2 System level concepts and terminology

The following sections introduce a number of concepts that are critical to understanding the system level description of the architecture:

- *Mode, state, and privilege level*
- *Exceptions* on page B1-1136.

The Virtualization Extensions, described in *The Virtualization Extensions* on page B1-1161, significantly affect some areas of ARM terminology. For consistency, this manual applies these changes across all ARMv7 implementations.

B1.2.1 Mode, state, and privilege level

Mode, state, and privilege level are key concepts in the ARM architecture.

Mode

The ARM architecture A and R profiles provide a set of modes that support normal software execution and handle exceptions. The current mode determines:

- the set of registers that are available to the processor
- the privilege level of the executing software.

For more information, see *ARM processor modes and ARM core registers* on page B1-1139.

State

In the ARM architecture, *state* describes the following distinct concepts:

Instruction set state

ARMv7 provides four instruction set states. The instruction set state determines the instruction set that is being executed, and is one of ARM state, Thumb state, Jazelle state, or ThumbEE state. *Instruction set state register, ISETSTATE* on page A2-50 gives more information about these states.

Execution state

The execution state consists of the instruction set state and some control bits that modify how the instruction stream is decoded. For details, see *Execution state registers* on page A2-50 and *Program Status Registers (PSRs)* on page B1-1147.

Security state In the ARM architecture, the number of security states depends on whether an implementation includes the Security Extensions:

- An implementation that includes the Security Extensions provides two security states, Secure state and Non-secure state. Each security state has its own system registers and memory address space.

  The security state is largely independent of the processor mode. The only exceptions to this independence of security state and processor mode are:

  — Monitor mode, that exists only in the Secure state, and supports transitions between Secure and Non-secure state

  — Hyp mode, part of the Virtualization Extensions, that exits only in the Non-secure state, because the Virtualization Extensions only support virtualization of the Non-secure state.

  Some system control resources are only accessible from the Secure state.

  For more information, see *The Security Extensions* on page B1-1156.

- An implementation that does not include the Security Extensions provides only a single security state.

In this manual:

- *Secure software* means software running in Secure state
- *Non-secure software* means software running in Non-secure state.

Debug state Debug state refers to the processor being halted for debug purposes, because a debug event has occurred when the processor is configured to Halting debug-mode. See *Invasive debug* on page C1-2021.

When the processor is not in Debug state it is described as being in Non-debug state.

Except where explicitly stated otherwise, parts A and B of this manual describe processor behavior and instruction execution in Non-debug state. Chapter C5 *Debug State* describes the differences in Debug state.

Privilege level

Privilege level is an attribute of software execution, in a particular security state, determined by the processor mode, as follows:

Secure state In Secure state there are two privilege levels:

PL0 Software executed in User mode executes at PL0.

PL1 Software executed in any mode other than User mode executes at PL1.

Non-secure state

In Non-secure state there are two or three privilege levels:

PL0 Software executed in User mode executes at PL0.

PL1 Software executed in any mode other than User or Hyp mode executes at PL1.

PL2 In an implementation that includes the Virtualization Extensions, software executed in Hyp mode executes at PL2.

Software execution at PL0 is sometimes described as unprivileged execution. A mode associated with a particular privilege level, PL*n*, can be described as a PL*n* mode.

Note

- The privilege level defines the ability to access resources in the current security state, and does not imply anything about the ability to access resources in the other security state.
- An implementation that does not include the Virtualization Extensions has no Non-secure resources that can be accessed only from the PL2 privilege level.

For more information see *Processor privilege levels, execution privilege, and access privilege* on page A3-141.

B1.2.2 Exceptions

An exception is a condition that changes the normal flow of control in a program. The change of flow switches execution to an exception handler, and the state of the system at the point where the exception occurred is presented to the exception handler. A key component of the state presented to the handler is the return address, that indicates the point in the instruction stream from which the exception was taken.

The ARM architecture provides a number of different exceptions as described in *Exception handling* on page B1-1164. The architecture defines the mode each exception is taken to. The Security Extensions and Virtualization Extensions add configuration settings that can determine the mode to which an exception is taken.

Terminology for describing exceptions

In this manual, a number of terms have specific meanings when describing exceptions:

- An exception is *generated* in one of the following ways:
  - Directly as a result of the execution or attempted execution of the instruction stream. For example, an exception is generated as a result of an undefined instruction.
  - Indirectly, as a result of something in the state of the system. For example, an exception is generated as a result of an interrupt signaled by a peripheral.
- An exception is *taken* by a processor at the point where it causes a change to the normal flow of control in the program.

  The mode in use immediately before an exception is taken is described as the mode the exception is *taken from*. The mode that is used on taking the exception is described as the mode the exception is *taken to*.

  The mode an exception is taken to is determined by:
  - the type of exception
  - the mode the exception is taken from
  - configuration settings in the Security Extensions and Virtualization Extensions.

  In an implementation that does not include the Security Extensions, the architecture defines the mode to which each exception is taken. This is called the *default mode* for that exception.
- An exception is described as *synchronous* if both of the following apply:
  - the exception is generated as a result of direct execution or attempted execution of the instruction stream
  - the return address presented to the exception handler is guaranteed to indicate the instruction that caused the exception.
- An exception is described as *asynchronous* if either of the following applies:
  - the exception is not generated as a result of direct execution or attempted execution of the instruction stream
  - the return address presented to the exception handler is not guaranteed to indicate the instruction that caused the exception.

Note

For a synchronous exception, the exception is taken from the mode in which it was generated. However, for an asynchronous exception, the processor mode might change after the exception is generated and before it is taken.

Asynchronous exceptions are classified as:

Precise asynchronous exceptions

The state presented to the exception handler is guaranteed to be consistent with the state at an identifiable instruction boundary in the execution stream from which the exception was taken.

Imprecise asynchronous exceptions

The state presented to the exception handler is not guaranteed to be consistent with any point in the execution stream from which the exception was taken.

Exceptions, privilege, and security state

ARMv7 has the following security state and privilege requirements for exception handling:

- Exceptions must be taken to a mode with a privilege level of PL1 or higher.
- Within a particular security state:
  - an exception must be taken to a mode with a privilege level greater than or equal to the privilege level of the mode the exception is taken from
  - exception return must be made to a mode with a privilege level less than or equal to the privilege level at which the exception handler is executing.

  In an implementation that does not include the Security Extensions, this requirement applies to the single security state of the processor.
- In an implementation that includes the Security Extensions:
  - An exception can be taken from any Non-secure mode, including Hyp mode, to Secure Monitor mode.

    Note

    In ARMv7, privilege levels are defined independently in each security state. Therefore, the rule about privilege levels is not relevant to taking an exception from a Non-secure mode to a Secure mode.
  - An exception can never be taken from a Secure mode to a Non-secure mode.

One effect of these requirements is that an exception taken from Non-secure Hyp mode must be taken to either:

- Non-secure Hyp mode
- Secure Monitor mode.

B1.3 ARM processor modes and ARM core registers

The following sections describe the ARM processor modes and the ARM core registers:

- *ARM processor modes*
- *ARM core registers* on page B1-1143
- *Program Status Registers (PSRs)* on page B1-1147
- *ELR_hyp* on page B1-1154.

B1.3.1 ARM processor modes

Table B1-1 shows the processor modes defined by the ARM architecture. In this table:

- the *Processor mode* column gives the name of each mode and the abbreviation used, for example, in the ARM core register name suffixes used in *ARM core registers* on page B1-1143
- the *Privilege level* column gives the privilege level of software executing in that mode, see *Privilege level* on page B1-1136
- the *Encoding* column gives the corresponding CPSR.M field
- the *Security state* column applies only to processors that implement the Security Extensions.

Table B1-1 ARM processor modes

Processor mode		Encoding	Privilege level	Implemented	Security state
User	usr	10000	PL0	Always	Both
FIQ	fiq	10001	PL1	Always	Both
IRQ	irq	10010	PL1	Always	Both
Supervisor	svc	10011	PL1	Always	Both
Monitor	mon	10110	PL1	With Security Extensions	Secure only
Abort	abt	10111	PL1	Always	Both
Hyp	hyp	11010	PL2	With Virtualization Extensions	Non-secure only
Undefined	und	11011	PL1	Always	Both
System	sys	11111	PL1	Always	Both

Mode changes can be made under software control, or can be caused by an external or internal exception.

Notes on the ARM processor modes

User mode An operating system runs applications in User mode to restrict the use of system resources. Software executing in User mode executes at PL0. Execution in User mode is sometimes described as unprivileged execution. Application programs normally execute in User mode, and any program executed in User mode:

- makes only unprivileged accesses to system resources, meaning it cannot access protected system resources
- makes only unprivileged access to memory
- cannot change mode except by causing an exception, see *Exception handling* on page B1-1164.

System mode Software executing in System mode executes at PL1. System mode has the same registers available as User mode, and is not entered by any exception.

Supervisor mode

Supervisor mode is the default mode to which a Supervisor Call exception is taken.

Executing a SVC (Supervisor Call) instruction generates an Supervisor Call exception, that is taken to Supervisor mode.

A processor enters Supervisor mode on Reset.

Abort mode Abort mode is the default mode to which a Data Abort exception or Prefetch Abort exception is taken.

Undefined mode

Undefined mode is the default mode to which an instruction-related exception, including any attempt to execute an UNDEFINED instruction, is taken.

FIQ mode FIQ mode is the default mode to which an FIQ interrupt is taken.

IRQ mode IRQ mode is the default mode to which an IRQ interrupt is taken.

Hyp mode Hyp mode is the Non-secure PL2 mode, implemented as part of the Virtualization Extensions. Hyp mode is entered on taking an exception from Non-secure state that must be taken to PL2

The Hypervisor Call exception and Hyp Trap exception are exceptions that are implemented as part of the Virtualization Extensions, and that are always taken in Hyp mode.

Note

This means that Hypervisor Call exceptions and Hyp Trap exceptions cannot be taken from Secure state.

In a Non-secure PL1 mode, executing a HVC (Hypervisor Call) instruction generates a Hypervisor Call exception.

For more information, see *Hyp mode* on page B1-1141.

Monitor mode

Monitor mode is the mode to which a Secure Monitor Call exception is taken.

In a PL1 mode, executing an SMC (Secure Monitor Call) instruction generates a Secure Monitor Call exception.

Monitor mode is a Secure mode, meaning it is always in the Secure state, regardless of the value of the SCR.NS bit.

Software running in Monitor mode has access to both the Secure and Non-secure copies of system registers. This means Monitor mode provides the normal method of changing between the Secure and Non-secure security states.

Note

It is important to distinguish between:

Monitor mode

This is a processor mode that is only available when an implementation includes the Security Extensions. It is used in normal operation, as a mechanism to transfer between Secure and Non-secure state, as described in this section.

Monitor debug-mode

This is a debug mode and is available regardless of whether the implementation includes the Security Extensions. For more information, see *About the ARM Debug architecture* on page C1-2021.

Monitor mode is implemented only as part of the Security Extensions. For more information, see *The Security Extensions* on page B1-1156.

Secure and Non-secure modes

In a processor that implements the Security Extensions, most mode names can be qualified as Secure or Non-secure, to indicate whether the processor is also in Secure state or Non-secure state. For example:

- if a processor is in Supervisor mode and Secure state, it is in *Secure Supervisor mode*
- if a processor is in User mode and Non-secure state, it is in *Non-secure User mode*.

Note

As indicated in the appropriate Mode descriptions:

- Monitor mode is a Secure mode, meaning it is always in the Secure state
- Hyp mode is a Non-secure mode, meaning it is accessible only in Non-secure state.

Figure B1-1 shows the modes, privilege levels, and security states, for an implementation that includes the Security Extensions and the Virtualization Extensions.

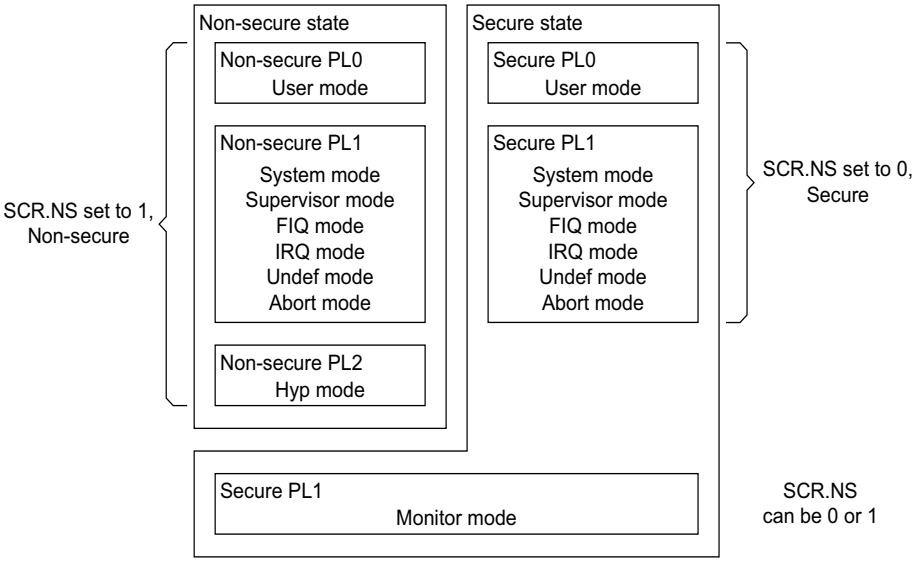


Figure B1-1 Modes, privilege levels, and security states

Hyp mode

Hyp mode is a Non-secure mode, implemented only as part of the Virtualization Extensions. It provides the usual method of controlling almost all of the functionality of the Virtualization Extensions.

Note

The alternative method of controlling this functionality is by accessing the Hyp mode controls from Secure Monitor mode, with the SCR.NS bit set to 1.

This section summarizes how Hyp mode differs from the other modes, and references where the features of Hyp mode are described in more detail:

- Software executing in Hyp mode executes at PL2, see *Mode, state, and privilege level* on page B1-1135.
- Hyp mode is accessible only in Non-secure state. When the processor is in Secure state, setting CPSR.M to `0b11010`, the encoding for Hyp mode, has no meaning. Therefore, in Secure state, the effect of attempting to set CPSR.M to `0b11010` is UNPREDICTABLE. For more information see *The Current Program Status Register (CPSR)* on page B1-1147.

- In Non-debug state, the only mechanisms for changing to Hyp mode are:
  - an exception taken from a Non-secure PL1 or PL0 mode
  - an exception return from Secure Monitor mode.
- In Hyp mode, the only exception return is execution of an ERET instruction, see *ERET* on page B9-1980.
- In Hyp mode, the CPACR has no effect on the execution of coprocessor, floating-point, or Advanced SIMD instructions. The HCPTR controls execution of these instructions in Hyp mode.
- If software running in Hyp mode executes an SVC instruction, the Supervisor Call exception generated by the instruction is taken to Hyp mode, see *SVC (previously SWI)* on page A8-720.
- The effect of an exception return with the restored CPSR specifying Hyp mode is UNPREDICTABLE if either:
  - SCR.NS is set to 0
  - the return is from a Non-secure PL1 mode.
- The instructions described in the following sections are UNDEFINED if executed in Hyp mode:
  - *SRS (Thumb)* on page B9-2002
  - *SRS (ARM)* on page B9-2004
  - *RFE* on page B9-1998
  - *LDM (exception return)* on page B9-1984
  - *LDM (User registers)* on page B9-1986
  - *STM (User registers)* on page B9-2006
  - *SUBS PC, LR and related instructions (ARM)* on page B9-2010.
  - *SUBS PC, LR (Thumb)* on page B9-2008, when executed with a nonzero constant.

    Note

    In Thumb state, ERET is encoded as `SUBS PC, LR, #0`, and therefore this is a valid instruction.
- The unprivileged Load unprivileged and Store unprivileged instructions LDRT, LDRSHT, LDRHT, LDRBT, STRT, STRHT, and STRBT, are UNPREDICTABLE if executed in Hyp mode.

From reset, the HVC instruction is UNDEFINED in Non-secure PL1 modes, meaning entry to Hyp mode is disabled by default. To permit entry to Hyp mode using the Hypervisor Call exception, Secure software must enable use of the HVC instruction by setting the SCR.HCE bit to 1. In addition, when SCR.HCE is set to 0, HVC is UNPREDICTABLE in Hyp mode.

Pseudocode details of mode operations

The BadMode() function tests whether a 5-bit mode number corresponds to one of the permitted modes:

```
// BadMode()
// =========

boolean BadMode(bits(5) mode)
    case mode of
        when '10000'  result = FALSE;               // User mode
        when '10001'  result = FALSE;               // FIQ mode
        when '10010'  result = FALSE;               // IRQ mode
        when '10011'  result = FALSE;               // Supervisor mode
        when '10110'  result = !HaveSecurityExt();  // Monitor mode
        when '10111'  result = FALSE;               // Abort mode
        when '11010'  result = !HaveVirtExt();      // Hyp mode
        when '11011'  result = FALSE;               // Undefined mode
        when '11111'  result = FALSE;               // System mode
        otherwise     result = TRUE;
    return result;
```

The following pseudocode functions provide information about the current mode:

```
// CurrentModeIsNotUser()
// ======================

boolean CurrentModeIsNotUser()
    if BadMode(CPSR.M) then UNPREDICTABLE;
    if CPSR.M == '10000' then return FALSE;  // User mode
    return TRUE;                             // Other modes
// CurrentModeIsUserOrSystem()
// ===========================

boolean CurrentModeIsUserOrSystem()
    if BadMode(CPSR.M) then UNPREDICTABLE;
    if CPSR.M == '10000' then return TRUE;  // User mode
    if CPSR.M == '11111' then return TRUE;  // System mode
    return FALSE;                           // Other modes

// CurrentModeIsHyp()
// ==================

boolean CurrentModeIsHyp()
    if BadMode(CPSR.M) then UNPREDICTABLE;
    if CPSR.M == '11010' then return TRUE;   // Hyp mode
    return FALSE;                            // Other modes
```

B1.3.2 ARM core registers

ARM core registers on page A2-45 describes the application level view of the ARM core registers. This view provides 16 ARM core registers, R0 to R12, the *stack pointer* (SP), the *link register* (LR), and the *program counter* (PC). These registers are selected from a larger set of registers, that includes *Banked* copies of some registers, with the current register selected by the execution mode. The implementation and banking of the ARM core registers depends on whether or not the implementation includes the Security Extensions, or the Virtualization Extensions. Figure B1-2 on page B1-1144 shows the full set of Banked ARM core registers, the Program Status Registers CPSR and SPSR, and the ELR_hyp Special register.

Note

- The architecture uses system level register names, such as R0_usr, R8_usr, and R8_fiq, when it must identify a specific register. The application level names refer to the registers for the current mode, and usually are sufficient to identify a register.
- The Security Extensions and Virtualization Extensions are supported only in the ARMv7-A architecture profile.
- The Virtualization Extensions require implementation of the Security Extensions.

Application level view	System level view								
	User	System	Hyp †	Supervisor	Abort	Undefined	Monitor ‡	IRQ	FIQ
R0	R0_usr								
R1	R1_usr								
R2	R2_usr								
R3	R3_usr								
R4	R4_usr								
R5	R5_usr								
R6	R6_usr								
R7	R7_usr								
R8	R8_usr								R8_fiq
R9	R9_usr								R9_fiq
R10	R10_usr								R10_fiq

Cells with no entry indicate that the User mode register is used.

Figure B1-2 ARM core registers, PSRs, and ELR_hyp, showing register banking

As described in *Processor mode for taking exceptions* on page B1-1172, on taking an exception the processor changes mode, unless it is already in the mode to which it must take the exception. Each mode that the processor might enter in this way has:

- A Banked copy of the stack pointer, for example SP_irq and SP_hyp.
- A register that holds a preferred return address for the exception. This is:
  - for each PL1 mode, a Banked copy of the link register, for example LR_und and LR_mon
  - for the PL2 mode, Hyp mode, the special register ELR_hyp.
- A saved copy of the CPSR, made on exception entry, for example SPSR_irq and SPSR_hyp.

In addition FIQ mode has Banked copies of the ARM core registers R8 to R12.

User mode and System mode share the same ARM core registers.

User mode, System mode, and Hyp mode share the same LR.

For more information about the application level view of the SP, LR, and PC, and the alternative descriptions of them as R13, R14 and R15, see *ARM core registers* on page A2-45.

Pseudocode details of ARM core register operations

The following pseudocode gives access to the ARM core registers:

```
// The names of the Banked core registers.

enumeration RName {RName_0usr, RName_1usr, RName_2usr, RName_3usr, RName_4usr, RName_5usr,
                   RName_6usr, RName_7usr, RName_8usr, RName_8fiq, RName_9usr, RName_9fiq,
                   RName_10usr, RName_10fiq, RName_11usr, RName_11fiq, RName_12usr, RName_12fiq,
                   RName_SPusr, RName_SPfiq, RName_SPirq, RName_SPsvc,
                   RName_SPabt, RName_SPund, RName_SPmon, RName_SPhyp,
                   RName_LRusr, RName_LRfiq, RName_LRirq, RName_LRsvc,
```

```
                  RName_LRabt, RName_LRund, RName_LRmon,
                  RName_PC};
// The physical array of Banked core registers.
//
// _R[RName_PC] is defined to be the address of the current instruction. The
// offset of 4 or 8 bytes is applied to it by the register access functions.

array bits(32) _R[RName];

// RBankSelect()
// =============

RName RBankSelect(bits(5) mode, RName usr, RName fiq, RName irq,
                  RName svc, RName abt, RName und, RName mon, RName hyp)
    if BadMode(mode) then
        UNPREDICTABLE;
    else
        case mode of
            when '10000'  result = usr;  // User mode

B1.3.3 Program Status Registers (PSRs)

The Application level programmers' model provides the Application Program Status Register, see *The Application Program Status Register (APSR)* on page A2-49. This is an application level alias for the *Current Program Status Register* (CPSR). The system level view of the CPSR extends the register, adding system level information.

Every mode that an exception can be taken to has its own saved copy of the CPSR, the *Saved Program Status Register* (SPSR), as shown in Figure B1-2 on page B1-1144. For example, the SPSR for Monitor mode is called SPSR_mon.

The Current Program Status Register (CPSR)

The *Current Program Status Register* (CPSR) holds processor status and control information:

- the APSR, see *The Application Program Status Register (APSR)* on page A2-49
- the current instruction set state, see *Instruction set state register, ISETSTATE* on page A2-50
- the execution state bits for the Thumb If-Then instruction, see *IT block state register, ITSTATE* on page A2-51
- the current endianness, see *Endianness mapping register, ENDIANSTATE* on page A2-53
- the current processor mode
- interrupt and asynchronous abort disable bits.

The non-APSR bits of the CPSR have defined reset values. These are shown in the `TakeReset()` pseudocode function, see *Reset* on page B1-1204.

Writes to the CPSR have side-effects on various aspects of processor operation. All of these side-effects, except for those on memory accesses associated with fetching instructions, are synchronous to the CPSR write. This means they are guaranteed:

- not to be visible to earlier instructions in the execution stream
- to be visible to later instructions in the execution stream.

The privilege level and address space of memory accesses associated with fetching instructions depend on the current privilege level and security state. Writes to CPSR.M can change one of both of the privilege level and security state. The effect, on memory accesses associated with fetching instructions, of a change of privilege level or security state is:

- Synchronous to the change of privilege level or security state, if that change is caused by an exception entry or exception return.
- Guaranteed not to be visible to any memory access caused by fetching an earlier instruction in the execution stream.
- Guaranteed to be visible to any memory access caused by fetching any instruction after the next context synchronization operation in the execution stream.

Note

See *Context synchronization operation* for the definition of this term.

- Might or might not affect memory accesses caused by fetching instructions between the mode change instruction and the point where the mode change is guaranteed to be visible.

See *Exception return* on page B1-1193 for the definition of exception return instructions.

The Saved Program Status Registers (SPSRs)

The purpose of an SPSR is to record the pre-exception value of the CPSR. On taking an exception, the CPSR is copied to the SPSR of the mode to which the exception is taken. Saving this value means the exception handler can:

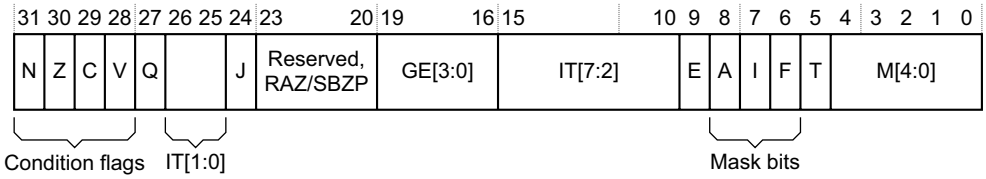
- on exception return, restore the CPSR to the value it had immediately before the exception was taken
- examine the value that the CPSR had when the exception was taken, for example to determine the instruction set state and privilege level in which the instruction that caused an Undefined Instruction exception was executed.

Figure B1-2 on page B1-1144 shows the banking of the SPSRs.

The SPSRs are UNKNOWN on reset. Any operation in a Non-secure PL1 or PL0 mode makes SPSR_hyp UNKNOWN.

Format of the CPSR and SPSRs

The CPSR and SPSR bit assignments are:



Condition flags, bits[31:28]

Set on the result of instruction execution. The flags are:

N, bit[31] Negative condition flag

Z, bit[30] Zero condition flag

C, bit[29] Carry condition flag

V, bit[28] Overflow condition flag.

The condition flags can be read or written in any mode, and are described in *The Application Program Status Register (APSR)* on page A2-49.

Q, bit[27] Cumulative saturation bit. This bit can be read or written in any mode, and is described in *The Application Program Status Register (APSR)* on page A2-49.

IT[7:0], bits[15:10, 26:25]

If-Then execution state bits for the Thumb `IT` (If-Then) instruction. *IT block state register, ITSTATE* on page A2-51 describes the encoding of these bits. CPSR.IT[7:0] are the IT[7:0] bits described there. For more information, see *IT* on page A8-390.

For details of how these bits can be accessed see *Accessing the execution state bits* on page B1-1150.

J, bit[24] Jazelle bit, see the description of the T bit, bit[5].

Bits[23:20] Reserved. RAZ/SBZP.

GE[3:0], bits[19:16]

Greater than or Equal flags, for the parallel addition and subtraction (SIMD) instructions described in *Parallel addition and subtraction instructions* on page A4-171.

The GE[3:0] field can be read or written in any mode, and is described in *The Application Program Status Register (APSR)* on page A2-49.

E, bit[9] Endianness execution state bit. Controls the load and store endianness for data accesses:

0 Little-endian operation

1 Big-endian operation.

Instruction fetches ignore this bit.

Endianness mapping register, ENDIANSTATE on page A2-53 describes the encoding of this bit. CPSR.E is the ENDIANSTATE bit described there.

For details of how this bit can be accessed see *Accessing the execution state bits* on page B1-1150.

When the reset value of the SCTLR.EE bit is defined by a configuration input signal, that value also applies to the CPSR.E bit on reset, and therefore applies to software execution from reset.

Mask bits, bits[8:6]

These bits are:

A, bit[8] Asynchronous abort mask bit.

I, bit[7] IRQ mask bit.

F, bit[6] FIQ mask bit.

The possible values of each bit are:

0 Exception not masked.

1 Exception masked.

The A bit has no effect on any Data Abort exception generated by a Watchpoint debug event, even if that exception is asynchronous. For more information see *Debug exception on Watchpoint debug event* on page C4-2089.

In an implementation that does not include the Security Extensions, setting a mask bit masks the corresponding exception, meaning it cannot be taken. However, the Security Extensions and Virtualization Extensions significantly alter the behavior and effect of these bits, see *Effects of the Security Extensions on the CPSR A and F bits* on page B1-1151 and *Asynchronous exception masking* on page B1-1183.

The mask bits can be written only at PL1 or higher. Their values can be read in any mode, but ARM deprecates any use of their values, or attempt to change them, by software executing at PL0.

Updates to the F bit are restricted if *Non-maskable FIQs* (NMFIs) are supported, see *Non-maskable FIQs* on page B1-1151.

T, bit[5] Thumb execution state bit. This bit and the J execution state bit, bit[24], determine the instruction set state of the processor, ARM, Thumb, Jazelle, or ThumbEE. *Instruction set state register, ISETSTATE* on page A2-50 describes the encoding of these bits. CPSR.J and CPSR.T are the same bits as ISETSTATE.J and ISETSTATE.T respectively. For more information, see *Instruction set states* on page B1-1155.

For details of how these bits can be accessed see *Accessing the execution state bits* on page B1-1150.

M[4:0], bits[4:0]

Mode field. This field determines the current mode of the processor. The permitted values of this field are listed in Table B1-1 on page B1-1139. All other values of M[4:0] are reserved. The effect of setting M[4:0] to a reserved value is UNPREDICTABLE.

Note

See the entry for *UNPREDICTABLE* in the Glossary for the restrictions on UNPREDICTABLE behavior. These restrictions mean that, for any CPSR.M value that is defined as UNPREDICTABLE in Non-secure state, the UNPREDICTABLE behavior must not cause entry to Secure state, or to any mode that the current configuration settings mean is not accessible in Non-secure state.

For more information about the processor modes see *ARM processor modes* on page B1-1139. Figure B1-2 on page B1-1144 shows the registers that can be accessed in each mode.

This field can be written only at PL1 or higher. Its value can be read in any mode, but ARM deprecates software executing at PL0 making any use of its value, or attempting to change it.

In an implementation that includes the Security Extensions, except as a result of an exception entry or exception return:

- Attempting to change CPSR.M to enter Monitor mode from Non-secure state is UNPREDICTABLE.
- When NSACR.RFR is set to 1, attempting to change CPSR.M to enter FIQ mode from Non-secure state is UNPREDICTABLE.

  From the introduction of the Virtualization Extensions, ARM deprecates any use of NSACR.RFR.

In an implementation that includes the Virtualization Extensions, except as a result of an exception entry or exception return:

- attempting to change CPSR.M to enter Hyp mode from any mode other than Hyp mode is UNPREDICTABLE
- attempting to change CPSR.M to enter any mode other than Hyp mode from Hyp mode is UNPREDICTABLE.

See *Exception return* on page B1-1193 for more information about constraints on the CPSR.M value on an exception return.

Accessing the execution state bits

The execution state bits are the IT[7:0], J, E, and T bits. If the current mode has an SPSR, software can read or write these bits in the SPSR.

In the CPSR, unless the processor is in Debug state:

- The execution state bits, other than the E bit, are RAZ when read by an `MRS` instruction.
- Writes to the execution state bits, other than the E bit, by an `MSR` instruction are:
  - For ARMv7 and ARMv6T2, ignored in all modes.
  - For architecture variants before ARMv6T2, ignored in User mode and required to write zeros in other modes. If a nonzero value is written at PL1, behavior is UNPREDICTABLE.

Instructions other than `MRS` and `MSR` that access the execution state bits can read and write them in any mode.

Unlike the other execution state bits in the CPSR, CPSR.E can be read by an `MRS` instruction and written by an `MSR` instruction. However, ARM deprecates:

- using the CPSR.E value read by an `MRS` instruction
- using an `MSR` instruction to change the value of CPSR.E.

Note

- Software can use the SETEND instruction to change the current endianness.
- To determine the current endianness, software can use an LDR instruction to load a word of memory with a known value that differs if the endianness is reversed. For example, using an LDR (literal) instruction to load a word whose four bytes are 0x01, 0x00, 0x00, and 0x00 in ascending order of memory address loads the destination register with:
  - 0x00000001 if the current endianness is little-endian
  - 0x01000000 if the current endianness is big-endian.

For more information about the behavior of these bits in Debug state see *Behavior of MRS and MSR instructions that access the CPSR in Debug state* on page C5-2097.

Non-maskable FIQs

Some ARMv7 implementations can be configured so that the CPSR.F bit cannot be set to 1 by an MSR or CPS instruction. This is defined as *Non-maskable FIQ* (NMFI) operation. In such an implementation, this configuration is controlled by a configuration input signal, that is asserted HIGH to enable NMFI operation.

Note

There is no software control of NMFI operation.

The Virtualization Extensions do not support NMFIs. Otherwise, it is IMPLEMENTATION DEFINED whether an ARMv7 processor supports NMFIs. In all cases, software can detect whether FIQs are maskable by reading the SCTLR.NMFI bit:

NMFI == 0 Software can mask FIQs by setting the CPSR.F bit to 1.

NMFI == 1 Software cannot set the CPSR.F bit to 1. This means software cannot mask FIQs.

For more information see either:

- *SCTLR, System Control Register, VMSA* on page B4-1705
- *SCTLR, System Control Register, PMSA* on page B6-1930.

When the SCTLR.NMFI bit is 1:

- an instruction writing 0 to the CPSR.F bit clears it to 0, but an instruction attempting to write 1 to it leaves it unchanged.
- CPSR.F can be set to 1 only by exception entries, as described in *CPSR.{A, I, F, M} values on exception entry* on page B1-1182.

In an implementation that includes the Security Extensions, this restriction on accessing CPSR.F interacts with the SCR.FW control, as described in *Effects of the Security Extensions on the CPSR A and F bits*.

Effects of the Security Extensions on the CPSR A and F bits

In an implementation that includes the Security Extensions:

- If the implementation does not include the Virtualization Extensions, when the processor is in Non-secure state:
  - the CPSR.F bit cannot be changed if the SCR.FW bit is set to 0
  - the CPSR.A bit cannot be changed if the SCR.AW bit is set to 0.
- If the implementation includes the Virtualization Extensions, clearing the SCR.FW and SCR.AW bits to 0 does not affect the ability to change the CPSR.F and CPSR.A bits, but does prevent those bit from masking exceptions in some situations.

For more information see *Asynchronous exception masking* on page B1-1183.

Note

For an implementation that includes the Security Extensions but not the Virtualization Extensions, when the processor is in the Non-secure state, software executing at PL1 can change the SPSR.F and SPSR.A bits even if the corresponding bits in the SCR are set to 0. However, when the SPSR is copied to the CPSR the CPSR.F and CPSR.A bits are not updated if the corresponding bits in the SCR are set to 0.

For an implementation that includes the Security Extensions but not the Virtualization Extensions, Table B1-2 shows how, in Non-secure state, SCR.FW interacts with SCTLR.NMFI to control possible updates to CPSR.F bit. The table includes the SCTLR.NMFI controls in Secure state.

Table B1-2 NMFI behavior, Security Extensions implemented without the Virtualization Extensions

Security state	SCR.FW bit	SCTLR.NMFI bit	CPSR.F bit properties
Secure	x	0	F bit can be written to 0 or 1
		1	F bit can be written to 0 but not to 1
Non-secure	0	x	F bit cannot be written
	1	0	F bit can be written to 0 or 1
		1	F bit can be written to 0 but not to 1

Note

The SCTLR.NMFI bit is common to the Secure and Non-secure versions of the SCTLR, because it is a read-only bit that reflects the value of a configuration input signal.

The Virtualization Extensions do not support NMFIs. In an implementation that includes the Virtualization Extensions, SCTLR.NMFI is RAZ.

Pseudocode details of PSR operations

The following pseudocode gives access to the PSRs:

```
bits(32) CPSR, SPSR_fiq, SPSR_irq, SPSR_svc, SPSR_mon, SPSR_abt, SPSR_und, SPSR_hyp;
// SPSR[] - non-assignment form
// ============================

        CPSR<9> = value<9>;                 // E bit is user-writable
        if privileged && (IsSecure() || SCR.AW == '1' || HaveVirtExt()) then
            CPSR<8> = value<8>;             // A interrupt mask

    if bytemask<0> == '1' then
        if privileged then
            CPSR<7> = value<7>;             // I interrupt mask
        if privileged && (!nmfi || value<6> == '0') &&
           (IsSecure() || SCR.FW == '1' || HaveVirtExt()) then
            CPSR<6> = value<6>;             // F interrupt mask
        if is_excpt_return then
            CPSR<5> = value<5>;             // T execution state bit
        if privileged then
            if BadMode(value<4:0>) then
                UNPREDICTABLE;
            else
                // Check for attempts to enter modes only permitted in Secure state from
                // Non-secure state. These are Monitor mode ('10110'), and FIQ mode ('10001')
                // if the Security Extensions have reserved it. The definition of UNPREDICTABLE
                // does not permit the resulting behavior to be a security hole.
                if !IsSecure() && value<4:0> == '10110' then UNPREDICTABLE;
                if !IsSecure() && value<4:0> == '10001' && NSACR.RFR == '1' then UNPREDICTABLE;
                // There is no Hyp mode ('11010') in Secure state, so that is UNPREDICTABLE
                if SCR.NS == '0' && value<4:0> == '11010' then UNPREDICTABLE;
                // Cannot move into Hyp mode directly from a Non-secure PL1 mode
                if !IsSecure() && CPSR.M != '11010' && value<4:0> == '11010' then
                    UNPREDICTABLE;
                // Cannot move out of Hyp mode with this function except on an exception return
                if CPSR.M == '11010' && value<4:0> != '11010' && !is_excpt_return then
                    UNPREDICTABLE;

                CPSR.M = value<4:0>;        // CPSR<4:0>, mode bits

    return;
```

```
// SPSRWriteByInstr()
// ==================

SPSRWriteByInstr(bits(32) value, bits(4) bytemask)

    if CurrentModeIsUserOrSystem() then UNPREDICTABLE;

    if bytemask<3> == '1' then
        SPSR[]<31:24> = value<31:24>;  // N,Z,C,V,Q flags, IT<1:0>,J execution state bits

    if bytemask<2> == '1' then
        // bits <23:20> are reserved SBZP bits
        SPSR[]<19:16> = value<19:16>;  // GE<3:0> flags

    if bytemask<1> == '1' then
        SPSR[]<15:8> = value<15:8>;    // IT<7:2> execution state bits, E bit, A interrupt mask

    if bytemask<0> == '1' then
        SPSR[]<7:5> = value<7:5>;      // I,F interrupt masks, T execution state bit
        if BadMode(value<4:0>) then    // Mode bits
            UNPREDICTABLE;
        else
            SPSR[]<4:0> = value<4:0>;

    return;
```

B1.3.4 ELR_hyp

Hyp mode does not provide its own Banked copy of LR. Instead, on taking an exception to Hyp mode, the preferred return address is stored in ELR_hyp, a 32-bit Special register implemented for this purpose.

ELR_hyp is implemented only as part of the Virtualization Extensions.

ELR_hyp can be accessed explicitly only by executing:

- an MRS or MSR instruction that targets ELR_hyp, see:
  - *MRS (Banked register)* on page B9-1990
  - *MSR (Banked register)* on page B9-1992.

The ERET instruction uses the value in ELR_hyp as the return address for the exception. For more information, see *ERET* on page B9-1980.

Software execution in any Non-secure PL1 or PL0 mode makes ELR_hyp UNKNOWN.

For more information about the use of ELR_hyp see *Exceptions* on page B1-1136.

B1.4 Instruction set states

The instruction set states are described in Chapter A2 *Application Level Programmers' Model* and application level operations on them are described there. This section supplies more information about how they interact with system level functionality, in the sections:

- *Exceptions and instruction set state*.
- *Unimplemented instruction sets*.

B1.4.1 Exceptions and instruction set state

If an exception is taken to a PL1 mode, the SCTLR.TE bit for the security state the exception is taken to determines the processor instruction set state that handles the exception, and if necessary, the processor changes to this instruction set state on exception entry.

If the exception is taken to Hyp mode, the HSCTLR.TE bit determines the processor instruction set state that handles the exception, and if necessary, the processor changes to this instruction set state on exception entry.

On coming out of reset, the processor starts execution in Supervisor mode, in the instruction set state determined by the reset value of SCTLR.TE.

For more information see:

- for a VMSA implementation:
  - *SCTLR, System Control Register, VMSA* on page B4-1705
  - *HSCTLR, Hyp System Control Register, Virtualization Extensions* on page B4-1590
- for a PMSA implementation, *SCTLR, System Control Register, PMSA* on page B6-1930.

For more information about exception entry see *Overview of exception entry* on page B1-1170.

B1.4.2 Unimplemented instruction sets

The CPSR.J and CPSR.T bits define the current instruction set state, see *Instruction set state register, ISETSTATE* on page A2-50.

In the ARMv7 architecture:

- The Jazelle state:
  - Before the introduction of the Virtualization Extensions, is optional. ARM does not recommend support for Jazelle state in any ARMv7 implementation.
  - Is obsoleted by the introduction of the Virtualization Extensions. An ARMv7-A implementation that includes the Virtualization Extensions cannot support Jazelle state.
- The ThumbEE state is optional in the ARMv7-R architecture. ARM does not recommend support for ThumbEE state in any ARMv7-R implementation.

Some system instructions permit setting CPSR.{J, T} to values that select an unimplemented instruction set state, for example setting CPSR.J to 1 and CPSR.T to 0 on an processor that does not implement the Jazelle state. If such values are written to CPSR.{J, T}, the implementation behaves in one of these ways:

- Sets CPSR.{J, T} to the requested values and causes the next instruction to generate an Undefined Instruction exception, as described in *Exception return to an unimplemented instruction set state* on page B1-1196.
- Does not set CPSR.{J, T} to the requested values. The processor might change the value of one or both of the bits in such a way that the new values correspond to an implemented instruction set state. If this is done then the instruction set state changes to this new state. The detailed behavior of the attempt to change to an unimplemented state is IMPLEMENTATION DEFINED.

B1.5 The Security Extensions

The Security Extensions are an OPTIONAL extension to the ARMv7-A architecture profile. When implemented, the Security Extensions integrate hardware security features into the architecture, to facilitate the development of secure applications. Many features of the architecture are extended to integrate with the Security Extensions, and because of this integration of the Security Extensions into the architecture, features of the Security Extensions are described in many sections of this manual.

Note

The Security Extensions are also permitted as an extension to the ARMv6K architecture. The resulting combination is sometimes called the ARMv6Z or ARMv6KZ architecture.

The following sections give general information about the Security Extensions:

- *Security states*
- *Impact of the Security Extensions on the modes and exception model* on page B1-1157
- *Security Extensions features added by the Virtualization Extensions* on page B1-1158
- *Classification of system control registers* on page B3-1451.

B1.5.1 Security states

The Security Extensions define two security states, Secure state and Non-secure state. All instruction execution takes place either in Secure state or in Non-secure state:

- Each security state operates in its own virtual memory address space, with its own *translation regime*.

  Note

  Figure B3-1 on page B3-1309 shows the different translation regimes.

- Many system controls can be set independently in each of the security states.
- All of the processor modes that are available in a system that does not implement the Security Extensions are available in each of the security states. However:
  - in any implementation that includes the Security Extensions, Monitor mode is available only in Secure state
  - in an implementation that also includes the Virtualization Extensions, Hyp mode is available only in Non-secure state.

The Security Extensions also define an additional processor mode, Monitor mode, that provides a bridge between software running in Non-secure state and software running in Secure state, see *Changing from Secure to Non-secure state* on page B1-1157.

The following features mean the two security states can provide more security than is typically provided by systems using the split between the different levels of execution privilege:

- the memory system provides mechanisms that prevent the Non-secure state accessing regions of the physical memory designated as Secure
- system controls that apply to the Secure state are not accessible from the Non-secure state
- entry to the Secure state from the Non-secure state is provided only by a small number of exceptions
- exit from the Secure state to the Non-secure state is provided only by a small number of mechanisms
- many operating system and hypervisor exceptions can be handled without changing security state.

The fundamental mechanism that determines the security state is the SCR.NS bit:

- For all modes other than Monitor mode and Hyp mode, the SCR.NS bit determines the security state for software execution.
- In an implementation that includes the Virtualization Extensions, Hyp mode is available only in Non-secure state, meaning it is available only when the SCR.NS bit is set to 1.
- Software executing in Monitor mode executes in the Secure state regardless of the value of the SCR.NS bit.

The ARM core registers and the processor status registers are not Banked between the Secure and the Non-secure states. ARM expects that, when switching execution between the Non-secure and Secure states, a kernel running mostly in Monitor mode will switch the values of these registers.

The registers LR_mon and SPSR_mon are UNKNOWN when executing in Non-secure state.

Many of the system registers referred to in *Coprocessors and system control* on page B1-1225 are Banked between the Secure and Non-secure security states. A Banked copy of a register applies only to execution in the appropriate security state. A small number of system registers are not Banked but apply to both the Secure and Non-secure security states. The registers that are not Banked relate to global system configuration options that ARM expects to be common to the two security states.

Changing from Secure to Non-secure state

Monitor mode is provided to support switching between Secure and Non-secure states. Except in Monitor mode and Hyp mode, the security state is controlled by the SCR.NS bit. Software executing in a Secure PL1 mode can change the SCR, but ARM strongly recommends that software obeys the following rules for changing SCR.NS:

- To avoid security holes, software must not:
  - Change from Secure to Non-secure state by using an `MSR` or `CPS` instruction to switch from Monitor mode to some other mode while SCR.NS is 1.
  - Use an `MCR` instruction that writes SCR.NS to change from Secure to Non-secure state. This means ARM recommends that software does not alter SCR.NS in any mode except Monitor mode. ARM deprecates changing SCR.NS in any other mode.
- The usual mechanism for changing from Secure to Non-secure state is an exception return.To return to Non-secure state, software executing in Monitor mode sets SCR.NS to 1 and then performs the exception return.

Pseudocode details of Secure state operations

The `HaveSecurityExt()` function returns TRUE if the implementation includes the Security Extensions, and FALSE otherwise.

The `IsSecure()` function returns TRUE if the processor is in Secure state, or if the implementation does not include the Security Extensions, and FALSE otherwise.

```
// IsSecure()
// ==========

boolean IsSecure()
    return !HaveSecurityExt() || SCR.NS == '0' || CPSR.M == '10110'; // Monitor mode
```

B1.5.2 Impact of the Security Extensions on the modes and exception model

This section gives an overview of the effect of the Security Extensions on the modes and exception model:

- Monitor mode is implemented only as part of the Security Extensions. For more information, see *ARM processor modes* on page B1-1139 and *Security states* on page B1-1156.
- The *Secure Monitor Call* (SMC) exception is implemented only as part of the Security Extensions. The `SMC` instruction generates this exception. For more information, see *Secure Monitor Call (SMC) exception* on page B1-1210 and *SMC (previously SMI)* on page B9-2000.

- For exceptions taken to any PL1 mode, because the SCTLR is Banked between the Secure and Non-secure states, the V and VE bits are defined independently for the Secure and Non-secure states. For each state:
  - the SCTLR.V bit controls whether the low or the high exception vectors are used
  - for the IRQ and FIQ exceptions, the SCTLR.VE bit controls whether the IRQ and FIQ vectors are IMPLEMENTATION DEFINED.

  For more information, see *Exception vectors and the exception base address* on page B1-1164.
- For exceptions taken to any PL1 mode, the base address for the low exception vectors is held in a register that is Banked between the two security states, meaning this base address is defined independently for each security state.

  Another register holds the base address for exceptions taken to Monitor mode.

  For more information, see *Exception vectors and the exception base address* on page B1-1164.
- Setting bits in the SCR to 1 causes one or more of external aborts, IRQs and FIQs to be taken to Monitor mode and to use the Monitor exception base address, see *Asynchronous exception routing controls* on page B1-1174.
- When an exception is taken from Monitor mode in Non-debug state, SCR.NS is set to zero, to ensure that the exception is taken to Secure state. However, if an exception is taken from Monitor mode in Debug state, the exception entry does not change the value of SCR.NS.

  Note

  Many uses of the Security Extensions can be simplified if the system is designed so that exceptions cannot be taken from Monitor mode.
- Clearing bits in the SCR to 0 prevents software executing in Non-secure state from being able to mask one or both of asynchronous aborts and FIQs. The mechanism to do this depends on whether the implementation includes the Virtualization Extensions, see *Asynchronous exception masking* on page B1-1183. With either mechanism:
  - clearing the SCR.AW bit to 0 prevents Non-secure masking of asynchronous aborts that are taken to Monitor mode
  - clearing the SCR.FW bit to 0 prevents Non-secure masking of FIQs that are taken to Monitor mode.

B1.5.3 Security Extensions features added by the Virtualization Extensions

In an implementation that includes the Virtualization Extensions, the following features are added to the Security Extensions:

- When the SCR.SIF bit is set to 1, any instruction fetched from Non-secure physical memory cannot be executed in Secure state. For more information, see *Restriction on Secure instruction fetch* on page B3-1361.
- SCTLR and HSCTLR include WXN bits that, when set to 1, prevent instruction execution from writable memory regions.

  Similarly, setting SCTLR.UWXN to 1 prevents instruction execution from any memory region that unprivileged software can write to.

  For more information see *Preventing execution from writable locations* on page B3-1361.
- When the SCR.SCD bit is set to 1, entry to Secure state by taking a Secure Monitor Call exception is disabled. This means that, when SCR.SCD is set to 1:
  - an `SMC` instruction executed in Non-secure state, and not trapped by the HCR.TSC mechanism described in *Trapping use of the SMC instruction* on page B1-1254, is UNDEFINED
  - an `SMC` instruction executed in a Secure PL1 mode is UNPREDICTABLE.

  For more information, see *SMC (previously SMI)* on page B9-2000.

B1.6 The Large Physical Address Extension

The Large Physical Address Extension is an OPTIONAL extension to the ARMv7-A architecture profile. Any implementation that includes the Large Physical Address Extension must also include the Multiprocessing Extensions.

The Large Physical Address Extension adds a new translation table format:

- the format used in an implementation that does not include the Large Physical Address Extension is now called the Short-descriptor format, see *Short-descriptor translation table format* on page B3-1324
- the format added by the Large Physical Address Extension is the Long-descriptor format, see *Long-descriptor translation table format* on page B3-1338.

An implementation that includes the Large Physical Address Extension must support both translation table formats.

Other effects of the Large Physical Address Extension are described throughout this manual, and include:

- Changes to the permitted attributes for Device memory regions, see *Summary of ARMv7 memory attributes* on page A3-126 and *Device and Strongly-ordered memory shareability, Large Physical Address Extension* on page A3-137.

  Note

  The ordering requirements for Device accesses are identical to those for Strongly-ordered accesses, see *Ordering requirements for memory accesses* on page A3-148.

- The addition of a requirement that `LDRD` and `STRD` accesses to 64-bit aligned locations are 64-bit single-copy atomic as seen by translation table walks and accesses to translation tables, see *Single-copy atomicity* on page A3-127.
- Requiring the Short-descriptor translation table format to include the *Privileged execute-never* (PXN) attribute, see *Memory attributes in the Short-descriptor translation table format descriptors* on page B3-1328.

  Note

  — In an implementation that does not include the Large Physical Address Extension, the inclusion of the PXN attribute in the Short-descriptor translation table format is OPTIONAL.

  — The Long-descriptor translation table format always includes the PXN attribute.

- An implementation that includes the Large Physical Address Extension must implement the Multiprocessing Extensions and therefore cannot include the FCSE, see *Use of the Fast Context Switch Extension* on page AppxI-2475.
- The Large Physical Address Extension:
  — Extends the DBGDRAR and DBGDSAR to 64 bits, to hold PAs of up to 40 bits.
  — Defines new formats for the DFSR, IFSR, and TTBCR, for use with the Long-descriptor translation table format.
  — Adds bits to the DFSR and IFSR formats used with the Long-descriptor translation table format. DFSR.CM indicates when a fault is caused by a cache maintenance or address translation operation. DFSR.LPAE and IFSR.LPAE indicate the translation table format in use when the fault was generated.
  — Extends the PAR to 64 bits, to hold PAs of up to 40 bits.
  — Extends TTBR0 and TTBR1 to 64 bits, to support the Long-descriptor translation table format.
  — Defines two *Memory Attribute Indirection Registers*, MAIR0 and MAIR1, to replace PRRR and NMRR when using the Long-descriptor translation table format.
  — Provides two IMPLEMENTATION DEFINED Auxiliary Memory Attribute Indirection Registers 0 AMAIR0 and AMAIR1.

- The introduction of the Large Physical Address Extension changes:
  - some terminology used for MMU faults, see *VMSAv7 MMU fault terminology* on page B3-1398
  - the naming of the address translation operations, see *Naming of the address translation operations, and operation summary* on page B3-1438.

B1.7 The Virtualization Extensions

The Virtualization Extensions are an OPTIONAL extension to the ARMv7-A architecture profile. Any implementation that includes the Virtualization Extensions must include the Security Extensions, the Large Physical Address Extension, and the Multiprocessing Extensions.

When implemented, the Virtualization Extensions provide a set of hardware features that support virtualizing the Non-secure state of an ARM VMSAv7 implementation. The basic model of a virtualized system involves:

- a hypervisor, running in Non-secure Hyp mode, that is responsible for switching Guest operating systems
- a number of Guest operating systems, each of which runs in the Non-secure PL1 and PL0 modes
- for each Guest operating system, applications, that usually run in User mode.

Note

A Guest OS runs on a *virtual machine*. However, its own view is that it is running on an ARM processor. Normally, a Guest OS is completely unaware:

- that it is running on a virtual machine
- of any other Guest OS.

Another way of describing virtualization is that:

- a Guest operating system, including all applications and tasks running under that operating system, runs on a virtual machine
- a hypervisor switches between virtual machines.

Each virtual machine is identified by a *virtual machine identifier* (VMID), assigned by the hypervisor.

Many features of the architecture are extended to integrate with the Virtualization Extensions, and because of this integration of the Virtualization Extensions into the architecture, features of the Virtualization Extensions are described in many sections of this manual. The key features are:

- Hyp mode is implemented only in Non-secure state, to support Guest OS management. Hyp mode operates in its own Non-secure virtual address space, that is different from the Non-secure virtual address space accessed from Non-secure PL0 and PL1 modes.
- The Virtualization Extensions provide controls to:
  - Define virtual values for a small number of identification registers. A read of the identification register by a Guest OS or its applications returns the virtual value.
  - Trap various other operations, including accesses to many other registers, and memory management operations. A trapped operation generates an exception that is taken to Hyp mode.

  These controls are configured by software executing in Hyp mode.
- With the Security Extensions, the Virtualization Extensions control the routing of interrupts and asynchronous Data Abort exceptions to the appropriate one of:
  - the current Guest OS
  - a Guest OS that is not currently running
  - the hypervisor
  - the Secure monitor.
- When an implementation includes the Virtualization Extensions, it provides independent *translation regimes* for memory accesses from:
  - Secure modes, the Secure PL1&0 translation regime
  - Non-secure Hyp mode, the Non-secure PL2 translation regime
  - Non-secure PL1 and PL0 modes, the Non-secure PL1&0 translation regime.

  Figure B3-1 on page B3-1309 shows these translation regimes.

- In the Non-secure PL1&0 translation regime, address translation occurs in two stages:
  - Stage 1 maps the *Virtual Address* (VA) to an *Intermediate Physical Address* (IPA). Typically, the Guest OS configures and controls this stage, and believes that the IPA is the *Physical Address* (PA)
  - Stage 2 maps the IPA to the PA. Typically, the hypervisor controls this stage, and a Guest OS is completely unaware of this translation.

  For more information, see *About address translation* on page B3-1311.

Impact of the Virtualization Extensions on the modes and exception model gives more information about many of these features.

B1.7.1 Impact of the Virtualization Extensions on the modes and exception model

This section summarizes the effect of the Virtualization Extensions on the modes and exception model. An implementation that includes the Virtualization Extensions:

- Implements a new Non-secure mode, Hyp mode. *Hyp mode* on page B1-1141 summarizes how Hyp mode differs from the other processor modes.
- Implements new exceptions, see:
  - *Hypervisor Call (HVC) exception* on page B1-1211
  - *Hyp Trap exception* on page B1-1208
  - *Virtual IRQ exception* on page B1-1220
  - *Virtual FIQ exception* on page B1-1222
  - *Virtual Abort exception* on page B1-1217.

  The Hypervisor Call and Hyp Trap exceptions are always taken to Hyp mode. The virtual exceptions are taken to Non-secure IRQ, FIQ, or Abort mode, see *The virtual exceptions* on page B1-1163.
- Implements a new register that holds the exception vector base address for exceptions taken to Hyp mode, the HVBAR.
- Provides controls that can be used to route IRQs, FIQs, and asynchronous aborts, to Hyp mode. This is possible only if Secure software has not routed the exception to Monitor mode, and applies only to exceptions taken from a Non-secure mode.

  For more information see *Asynchronous exception routing controls* on page B1-1174.
- Provides controls that can be used to route some synchronous exceptions, taken from Non-secure modes, to Hyp mode. For more information see *Routing general exceptions to Hyp mode* on page B1-1191 and *Routing Debug exceptions to Hyp mode* on page B1-1193.
- Provide mechanisms to trap processor functions to Hyp mode, using the Hyp Trap exception, see *Traps to the hypervisor* on page B1-1247.

  When an operation is trapped to Hyp mode, the hypervisor typically either:
  - emulates the required operation, so the application running in the Guest OS is unaware of the trap to Hyp mode
  - returns an error to the Guest OS.
- Implements enhanced exception reporting for exceptions taken to Hyp mode, see *Reporting exceptions taken to the Non-secure PL2 mode* on page B3-1420. These exceptions are reported using the HSR, see *Use of the HSR* on page B3-1424,
- Implements a new exception return instruction, `ERET`, for return from Hyp mode. For more information see *Hyp mode* on page B1-1141.

The virtual exceptions

The Virtualization Extensions introduce three virtual exceptions:

- the Virtual IRQ exception, that corresponds to the physical IRQ exception
- the Virtual FIQ exception, that corresponds to the physical FIQ exception
- the Virtual Abort exception, that corresponds to a physical Data Abort or Prefetch Abort exception.

Software executing in Hyp mode can use these to signal exceptions to the other Non-secure modes. A Non-secure PL1 or PL0 mode cannot distinguish a virtual exception from the corresponding physical exception.

A usage model for these exceptions is that physical IRQs, FIQs and asynchronous aborts that occur when the processor is in a Non-secure PL1 or PL0 mode are routed to Hyp mode. The exception handler, executing in Hyp mode, determines whether the exception can be handled in Hyp mode or requires routing to a Guest OS. When an exception requires handling by a Guest OS it is marked as pending for that Guest OS. When the hypervisor switches to a particular Guest OS, it uses the appropriate virtual exception to signal any pending virtual exception to that Guest OS.

For more information see *Virtual exceptions in the Virtualization Extensions* on page B1-1196.

B1.8 Exception handling

An exception causes the processor to suspend program execution to handle an event, such as an externally generated interrupt or an attempt to execute an undefined instruction. Exceptions can be generated by internal and external sources.

Normally, when an exception is taken the processor state is preserved immediately, before handling the exception. This means that, when the event has been handled, the original state can be restored and program execution resumed from the point where the exception was taken.

More than one exception might be generated at the same time, and a new exception can be generated while the processor is handling an exception.

The following sections describe exception handling:

- *Exception vectors and the exception base address*
- *Exception priority order* on page B1-1168
- *Overview of exception entry* on page B1-1170
- *Processor mode for taking exceptions* on page B1-1172
- *Processor state on exception entry* on page B1-1181
- *Asynchronous exception masking* on page B1-1183
- *Summaries of asynchronous exception behavior* on page B1-1185
- *Routing general exceptions to Hyp mode* on page B1-1191
- *Routing Debug exceptions to Hyp mode* on page B1-1193
- *Exception return* on page B1-1193
- *Virtual exceptions in the Virtualization Extensions* on page B1-1196
- *Low interrupt latency configuration* on page B1-1197.
- *Wait For Event and Send Event* on page B1-1199
- *Wait For Interrupt* on page B1-1202.

Exception descriptions on page B1-1204 then describes each exception.

B1.8.1 Exception vectors and the exception base address

When an exception is taken, processor execution is forced to an address that corresponds to the type of exception. This address is called the *exception vector* for that exception.

A set of exception vectors comprises eight consecutive word-aligned memory addresses, starting at an *exception base address*. These eight vectors form a *vector table*. For the IRQ and FIQ exceptions only, when the exceptions are taken to IRQ mode and FIQ mode, software can change the exception vectors from the vector table values by setting the SCTLR.VE bit to 1, see *Vectored interrupt support* on page B1-1167.

The number of possible exception base addresses, and therefore the number of vector tables, depends on the implemented architecture profile and extensions, as follows:

Implementation that does not include the Security Extensions

This section applied to all ARMv7-R implementations.

An implementation that does not include the Security Extensions has a single vector table, the base address of which is selected by SCTLR.V, see *SCTLR, System Control Register, VMSA* on page B4-1705 or *SCTLR, System Control Register, PMSA* on page B6-1930:

V == 0 Exception base address = `0x00000000`. This setting is referred to as normal vectors, or as low vectors.

V == 1 Exception base address = `0xFFFF0000`. This setting is referred to as high vectors, or *Hivecs*.

Note

ARM deprecates using the Hivecs setting, SCTLR.V == 1, in ARMv7-R. ARM recommends that Hivecs is used only in ARMv7-A implementations.

Implementation that includes the Security Extensions

Any implementation that includes the Security Extensions has the following vector tables:

- One for exceptions taken to Secure Monitor mode. This is the Monitor vector table, and is in the address space of the Secure PL1&0 translation regime.
- One for exceptions taken to Secure PL1 modes other than Monitor mode. This is the Secure vector table, and is in the address space of the Secure PL1&0 translation regime.
- One for exceptions taken to Non-secure PL1 modes. This is the Non-secure vector table, and is in the address space of the Non-secure PL1&0 translation regime.

For the Monitor vector table, MVBAR holds the Exception base address.

For the Secure vector table:

- the Secure SCTLR.V bit determines the Exception base address:

  V == 0 The Secure VBAR holds the Exception base address.

  V == 1 Exception base address = `0xFFFF0000`, the Hivecs setting.

For the Non-secure vector table:

- the Non-secure SCTLR.V bit determines the Exception base address:

  V == 0 The Non-secure VBAR holds the Exception base address.

  V == 1 Exception base address = `0xFFFF0000`, the Hivecs setting.

Implementation that includes the Virtualization Extensions

An implementation that includes the Virtualization Extensions must include the Security Extensions, and also includes an additional vector table. Therefore, it has the following vector tables:

- One for exceptions taken to Secure Monitor mode. This is the Monitor vector table, and is in the address space of the Secure PL1&0 translation regime.
- One for exceptions taken to Secure PL1 modes other than Monitor mode. This is the Secure vector table, and is in the address space of the Secure PL1&0 translation regime.
- One for exceptions taken to Hyp mode, the Non-secure PL2 mode. This is the Hyp vector table, and is in the address space of the Non-secure PL2 translation regime.
- One for exceptions taken to Non-secure PL1 modes. This is the Non-secure vector table, and is in the address space of the Non-secure PL1&0 translation regime.

The Exception base addresses of the Monitor vector table, the Secure vector table, and the Non-secure vector table are determined in the same way as for an implementation that includes the Security extensions but not the Virtualization extensions.

For the Hyp vector table, HVBAR holds the Exception base address.

The following subsections give more information:

- *The vector tables and exception offsets*
- *Vectored interrupt support* on page B1-1167
- *Pseudocode determination of the exception base address* on page B1-1167.

The vector tables and exception offsets

Table B1-3 on page B1-1166 defines the vector table entries. In this table:

- The *Hyp mode* column defines the vector table entries for exceptions taken to Hyp mode.
- The *Monitor mode* column defines the vector table entries for exceptions taken to Monitor mode.
- The *Secure* and *Non-secure* columns define the Secure and Non-secure vector table entries, that are used for exceptions taken to PL1 modes other than Monitor mode. Table B1-4 on page B1-1166 shows the mode to which each of these exceptions is taken. Each of these modes is described as the *default* mode for taking the corresponding exception.

For more information about determining the mode to which an exception is taken, see *Processor mode for taking exceptions* on page B1-1172.

The Virtualization Extensions provide a number of additional exceptions, some of which are not shown explicitly in the vector tables. For more information, see *Offsets of exceptions introduced by the Virtualization Extensions*.

Table B1-3 The vector tables

Offset	Vector tables			
	Hyp[a]	Monitor[b]	Secure	Non-secure
0x00	Not used	Not used	Reset	Not used
0x04	Undefined Instruction, from Hyp mode	Not used	Undefined Instruction	Undefined Instruction
0x08	Hypervisor Call, from Hyp mode	Secure Monitor Call	Supervisor Call	Supervisor Call
0x0C	Prefetch Abort, from Hyp mode	Prefetch Abort	Prefetch Abort	Prefetch Abort
0x10	Data Abort, from Hyp mode	Data Abort	Data Abort	Data Abort
0x14	Hyp Trap, or Hyp mode entry[c]	Not used	Not used	Not used
0x18	IRQ interrupt	IRQ interrupt	IRQ interrupt	IRQ interrupt
0x1C	FIQ interrupt	FIQ interrupt	FIQ interrupt	FIQ interrupt

a. Non-secure state only. Implemented only if the implementation includes the Virtualization Extensions.
b. Secure state only. Implemented only if the implementation includes the Security Extensions.
c. See *Use of offset 0x14 in the Hyp vector table* on page B1-1167.

Table B1-4 Modes for taking exceptions using the Secure or Non-secure vector table

Exception	PL1 Mode taken to
Reset	Supervisor
Undefined Instruction	Undefined
Supervisor Call	Supervisor
Prefetch Abort	Abort
Data Abort	Abort
IRQ interrupt	IRQ
FIQ interrupt	FIQ

For more information about use of the vector tables see *Overview of exception entry* on page B1-1170.

Offsets of exceptions introduced by the Virtualization Extensions

The Virtualization Extensions introduce the following new exceptions. The processor enters the handlers for these exceptions using the following vector table entries shown in Table B1-3:

Hypervisor Call
If taken from Hyp mode, shown explicitly in the Hyp mode vector table. Otherwise, see *Use of offset 0x14 in the Hyp vector table* on page B1-1167.

Hyp Trap Shown explicitly in the Hyp mode vector table.

Virtual Abort Entered through the Data Abort vector in the Non-secure vector table.

Virtual IRQ Entered through the IRQ vector in the Non-secure vector table.

Virtual FIQ Entered through the FIQ vector in the Non-secure vector table.

Note

The virtual exceptions on page B1-1163 summarizes these exceptions, and *Virtual exceptions in the Virtualization Extensions* on page B1-1196 gives more information.

Use of offset `0x14` in the Hyp vector table

The vector at offset `0x14` in the Hyp vector table is used for exceptions that cause entry to Hyp mode. This means it is:

- Always used for the Hyp Trap exception.
- Used for the following exceptions, when the exception is not taken from Hyp mode:
  - Hypervisor Call
  - Supervisor Call, when caused by execution of an `SVC` instruction in Non-secure User mode when HCR.TGE is set to 1
  - Undefined Instruction
  - Prefetch Abort
  - Data Abort.

  Table B1-3 on page B1-1166 shows the offsets used for these exceptions when they are taken from Hyp mode.
- Never used for IRQ exceptions, Virtual IRQ exceptions, FIQ exceptions, or Virtual FIQ exceptions.

For more information, see *Processor mode for taking exceptions* on page B1-1172.

Pseudocode determination of the exception base address

For an exception taken to a PL1 mode other than Monitor mode, the `ExcVectorBase()` function determines the exception base address:

```
// ExcVectorBase()
// ===============

bits(32) ExcVectorBase()
    if SCTLR.V == '1' then  // Hivecs selected, base = 0xFFFF0000
        return Ones(16):Zeros(16);
    elsif HaveSecurityExt() then
        return VBAR;
    else
        return Zeros(32);
```

Vectored interrupt support

At reset, any implemented vectored interrupt mechanism is disabled, and the IRQ and FIQ exception vectors are at fixed offsets from the exception base address that is being used. With this configuration, an FIQ or IRQ handler typically starts with an instruction sequence that determines the cause of the interrupt and then branches to an appropriate routine to handle it.

If an implementation supports vectored interrupts, enabling this feature means an interrupt controller can prioritize interrupts and provide the address of the required interrupt handler directly to the processor, for use as the interrupt vector. For interrupts taken to PL1 modes other than Monitor mode, vectored interrupt behavior is enabled by setting the SCTLR.VE bit to 1, see either:

- *SCTLR, System Control Register, VMSA* on page B4-1705
- *SCTLR, System Control Register, PMSA* on page B6-1930.

The hardware that supports vectored interrupts is IMPLEMENTATION DEFINED, and an implementation might not include any support for this operation.

In an implementation that includes the Security Extensions:

- The SCTLR.VE bit is Banked between Secure and Non-secure states to provide independent control of whether vectored interrupt support is enabled.
- Interrupts can be routed to Monitor mode, by setting either or both of the SCR.IRQ and SCR.FIQ bits to 1. When an interrupt is routed to Monitor mode it uses the vector in the vector table at the Monitor exception base address held in MVBAR, regardless of the value of either Banked copy of the SCTLR.VE bit.

The Virtualization Extensions do not support this vectoring of the IRQ and FIQ exceptions when these exceptions are routed to Hyp mode. When an interrupt is routed to Hyp mode, it uses the vector in the vector table at the Hyp exception base address held in HVBAR, regardless of the value of either Banked copy of the SCTLR.VE bit.

From the introduction of the Virtualization Extensions, ARM deprecates any use of the SCTLR.VE bit.

B1.8.2 Exception priority order

An instruction is not valid if it generates a synchronous Prefetch Abort exception. Therefore, if an instruction generates a Prefetch Abort exception, no other synchronous exception or debug event is generated on that instruction.

A Breakpoint debug event, or an address matching form of the Vector catch debug event, is associated with the instruction. This means the corresponding exception is taken before the instruction is executed. Therefore, when a Breakpoint or address matching Vector catch debug event occurs, no other synchronous exception or debug event, that might have occurred as a result of executing the instruction, can occur.

Note

- The Exception trapping form of the Vector catch debug event, introduced in v7.1 Debug, causes a debug event as a result of trapping an exception that has been prioritized as described in this section. This means it is outside the scope of the description in this section. For more information see *Vector catch debug events* on page C3-2065.
- In v7 Debug, the only supported Vector catch debug events are address matching Vector catch debug events.

Otherwise:

- An instruction that generates an Undefined Instruction exception or a Hyp Trap exception cannot cause any memory access, and therefore cannot cause a Data Abort exception.
- If an instruction generates both an Undefined Instruction exception and a Hyp Trap exception then, unless this manual explicitly states otherwise, the Undefined Instruction exception has priority.
- If a system call is configured to generate an Undefined Instruction exception or a Hyp Trap exception, then the Undefined Instruction exception or the Hyp Trap exception has priority over the system call. The system calls are the `SVC`, `HVC`, and `SMC` instructions.
- A memory access that generates an MMU fault, an MPU fault, or a synchronous Watchpoint debug event must not generate an external abort.
- All other synchronous exceptions are mutually exclusive and are derived from a decode of the instruction.

For more information, see:

- *Debug event prioritization* on page C3-2076 for information about the prioritization of debug events, including their prioritization relative to MMU faults, MPU faults, and synchronous external aborts
- *Prioritization of aborts* on page B3-1407, for information about:
  - the prioritization of aborts on a single memory access in a VMSA implementation
  - the prioritization of exceptions generated during address translation

- *Prioritization of aborts* on page B5-1766, for information about the prioritization of aborts on a single memory access in a PMSA implementation.

Architectural requirements for taking asynchronous exceptions

The ARM architecture does not define when asynchronous exceptions are taken, but sets the following limits on when they are taken:

- An asynchronous exception that is pending before one of the following context synchronizing events is taken before the first instruction after the context synchronizing event completes its execution, provided that the pending asynchronous event is not masked after the context synchronizing event. The context synchronizing events are:
  - Execution of an `ISB` instruction.
  - Taking an exception.
  - Return from an exception.
  - Exit from Debug state.

  The ISR identifies any pending asynchronous exceptions.

  Note

  If the first instruction after the context synchronizing event generates a synchronous exception, then the architecture does not define the order in which that synchronous exception and the asynchronous exception are taken.

- In the absence of an specific requirement to take an asynchronous exception, because of a context synchronizing event, the only requirement of the architecture is that an unmasked asynchronous exception is taken in finite time.

  Note

  The taking of an unmasked asynchronous exception in finite time must occur with all code sequences, including with a sequence that consists of unconditional loops.

Within these limits, the prioritization of asynchronous exceptions relative to other exceptions, both synchronous and asynchronous, is IMPLEMENTATION DEFINED.

Note

A special requirement applies to asynchronous watchpoints, see *Debug event prioritization* on page C3-2076.

The CPSR includes a mask bit for each type of asynchronous exception. Setting one of these bits to 1 can prevent the corresponding asynchronous exception from being taken, see *Summaries of asynchronous exception behavior* on page B1-1185.

Taking an exception sets an exception-dependent subset of these mask bits.

Note

The subset of the CPSR mask bits that is set on taking an exception can prioritize the execution of FIQ handlers over that of IRQ and asynchronous abort handlers.

B1.8.3 Overview of exception entry

On taking an exception:

1. The hardware determines the mode to which the exception must be taken, see *Processor mode for taking exceptions* on page B1-1172.
2. A link value, indicating the *preferred return address* for the exception, is saved. This is a possible return address for the exception handler, and depends on:
   - the exception type
   - whether the exception is taken to a PL1 mode or a PL2 mode
   - for some exceptions taken to a PL1 mode, the instruction set state when the exception is taken.

   Where the link value is saved depends on whether the exception is taken to a PL1 mode or a PL2 mode.

   For more information see *Link values saved on exception entry* on page B1-1171.
3. The value of the CPSR is saved in the SPSR for the mode to which the exception must be taken. The value saved in SPSR.IT[7:0] is always correct for the preferred return address.
4. In an implementation that includes the Security Exceptions:
   - if the exception taken from Monitor mode, SCR.NS is cleared to 0
   - otherwise, taking the exception leaves SCR.NS unchanged.
5. The CPSR is updated with new context information for the exception handler. This includes:
   - Setting CPSR.M to the processor mode to which the exception is taken.
   - Setting the appropriate CPSR mask bits. This can disable the corresponding exceptions, preventing uncontrolled nesting of exception handlers.
   - Setting the instruction set state to the state required for exception entry.
   - Setting the endianness to the required value for exception entry.
   - Clearing the CPSR.IT[7:0] bits to 0.

   For more information, see *Processor state on exception entry* on page B1-1181.
6. The appropriate exception vector is loaded into the PC, see *Exception vectors and the exception base address* on page B1-1164.
7. Execution continues from the address held in the PC.

For an exception taken to a PL1 mode, on exception entry, the exception handler can use the SRS instruction to store the return state onto the stack of any mode at the same privilege level, and the CPS instruction to change mode. For more information about the instructions, see *SRS (Thumb)* on page B9-2002, *SRS (ARM)* on page B9-2004, *CPS (Thumb)* on page B9-1976, and *CPS (ARM)* on page B9-1978.

Later sections of this chapter describe each of the possible exceptions, and each of these descriptions includes a pseudocode description of the processor state changes when it takes that exception. Table B1-5 gives an index to these descriptions:

Table B1-5 Pseudocode descriptions of exception entry

Exception	Description of exception entry
Reset	*Pseudocode description of taking the Reset exception* on page B1-1205
Undefined Instruction	*Pseudocode description of taking the Undefined Instruction exception* on page B1-1207
Supervisor Call	*Pseudocode description of taking the Supervisor Call exception* on page B1-1209
Secure Monitor Call	*Pseudocode description of taking the Secure Monitor Call exception* on page B1-1211
Hypervisor Call	*Pseudocode description of taking the Hypervisor Call exception* on page B1-1212
Prefetch Abort	*Pseudocode description of taking the Prefetch Abort exception* on page B1-1213

Table B1-5 Pseudocode descriptions of exception entry (continued)

Exception	Description of exception entry
Data Abort	*Pseudocode description of taking the Data Abort exception* on page B1-1215
IRQ	*Pseudocode description of taking the IRQ exception* on page B1-1219
FIQ	*Pseudocode description of taking the FIQ exception* on page B1-1221
Hyp Trap	*Pseudocode description of taking the Hyp Trap exception* on page B1-1209
Virtual Abort	*Pseudocode description of taking the Virtual Abort exception* on page B1-1217
Virtual IRQ	*Pseudocode description of taking the Virtual IRQ exception* on page B1-1220
Virtual FIQ	*Pseudocode description of taking the Virtual FIQ exception* on page B1-1223

The following sections give more information about the processor state changes, for different architecture implementations. However, you must refer to the pseudocode for a full description of the state changes:

- *Processor mode for taking exceptions* on page B1-1172
- *Processor state on exception entry* on page B1-1181.

Link values saved on exception entry

On exception entry, a link value for use on return from the exception, is saved. This link value is based on the *preferred return address for the exception*, as shown in Table B1-6:

Table B1-6 Exception return addresses

Exception	Preferred return address	Taken to a mode at
Undefined Instruction	Address of the UNDEFINED instruction	PL1[a], or PL2[b]
Supervisor Call	Address of the instruction after the SVC instruction	PL1[a] or PL2[b]
Secure Monitor Call	Address of the instruction after the SMC instruction	PL1, and only in Secure state
Hypervisor Call	Address of the instruction after the HVC instruction	PL2 only[b]
Prefetch Abort	Address of aborted instruction fetch	PL1[a] or PL2[b]
Data Abort	Address of instruction that generated the abort	PL1[a] or PL2[b]
Virtual Abort	Address of next instruction to execute	PL1, and only in Non-secure state
Hyp Trap	Address of the trapped instruction	PL2 only[b]
IRQ or FIQ	Address of next instruction to execute	PL1[a] or PL2[b]
Virtual IRQ or Virtual FIQ	Address of next instruction to execute	PL1, and only in Non-secure state

a. Secure or Non-secure.

b. PL2 is implemented only in Non-secure state. Therefore, an exception can be taken to PL2 mode only if it is taken from Non-secure state.

Note

- Although Reset is described as an exception, it differs significantly from other exceptions. The architecture has no concept of a return from a Reset and therefore it is not listed in this section.
- For each exception, the preferred return address is not affected by whether the exception is taken from a PL1 mode or from a PL0 mode.

However, the link value saved, and where it is saved, depend on whether the exception is taken to a PL1 mode, or to a PL2 mode, as follows:

Exception taken to a PL1 mode

The link value is saved in the LR for the mode to which the exception is taken.

The saved link value is the preferred return address for the exception, plus an offset that depends on the instruction set state when the exception was taken, as Table B1-7 shows:

Table B1-7 Offsets applied to Link value for exceptions taken to PL1 modes

Exception	Offset, for processor state of:		
	ARM	Thumb[a]	Jazelle
Undefined Instruction	+4	+2	-[b]
Supervisor Call	None	None	-[c]
Secure Monitor Call	None	None	-[c]
Prefetch Abort	+4	+4	+4
Data Abort	+8	+8	+8
Virtual Abort	+8	+8	+8
IRQ or FIQ	+4	+4	+4
Virtual IRQ or Virtual FIQ	+4	+4	+4

a. Thumb or ThumbEE state.
b. See *Undefined Instruction exception in Jazelle state* on page B1-1207.
c. Exception cannot occur in Jazelle state.

Exception taken to a PL2 mode

The link value is saved in the ELR_hyp Special register.

The saved link value is the preferred return address for the exception, as shown in Table B1-6 on page B1-1171, with no offset.

B1.8.4 Processor mode for taking exceptions

The following principles determine the mode to which an exception is taken:

- An exception cannot be taken to a PL0 mode.
- An exception is taken either:
  - at the privilege level at which the processor was executing when it took the exception
  - at a higher privilege level.

  This means that, in Secure state, an exception is always taken to a PL1 mode.
- Configuration options and other features provided by the Security Extensions and the Virtualization Extensions can determine the mode to which some exceptions are taken, as follows:

  In an implementation that does not include the Security Extensions

  An exception is always taken to the default mode for that exception.

  Note

  An implementation that includes the Virtualization Extensions must also include the Security Extensions.

In an implementation that includes the Security Extensions

A Secure Monitor Call exception is always taken to Secure Monitor mode.

IRQ, FIQ, and External abort exceptions can be configured to be taken to Secure Monitor mode.

Any exception taken from Secure state that is not taken to Secure Monitor mode is taken to Secure state in the default mode for that exception.

If the implementation does not include the Virtualization Extensions, any exception taken from Non-secure state that is not taken to Secure Monitor mode is taken to Non-secure state in the default mode for that exception.

In an implementation that includes the Virtualization Extensions

An exception taken from Non-secure state that is not taken to Secure Monitor mode is taken to Non-secure state and:

- if the exception is taken from Hyp mode then it is taken to Hyp mode
- otherwise, the exception is either taken to Hyp mode, as described in *Exceptions taken to Hyp mode*, or taken to the default mode for the exception.

Note

The Virtualization Extensions have no effect on the handling of exceptions taken from Secure state.

Table B1-4 on page B1-1166 shows the default mode to which each exception is taken.

Asynchronous exception routing controls on page B1-1174 describes the exception routing controls provided by the Security Extensions and the Virtualization Extensions.

For a VMSA implementation, *Routing of aborts* on page B3-1396 gives more information about the modes to which memory aborts are taken.

Summary of the possible modes for taking each exception on page B1-1174 shows all modes to which each exception might be taken, in any implementation. That is, it applies to implementations:

- that include neither the Security Extensions, nor the Virtualization Extensions
- that include the Security Extensions, but not the Virtualization Extensions
- that include both the Security Extensions and the Virtualization Extensions.

Exceptions taken to Hyp mode

In an implementation that includes the Virtualization Extensions:

- Any exception taken from Hyp mode, that is not routed to Secure Monitor Mode by the controls described in *Asynchronous exception routing controls* on page B1-1174, is taken to Hyp mode.
- The following exceptions, if taken from Non-secure state, are taken to Hyp mode:
  - An abort that *Routing of aborts* on page B3-1396 identifies as taken to Hyp mode.
  - A Hyp Trap exception, see *Traps to the hypervisor* on page B1-1247.
  - A Hypervisor Call exception. This is generated by executing a `HVC` instruction in a Non-secure mode.
  - An asynchronous abort, IRQ exception or FIQ exception that is not routed to Secure Monitor mode but is explicitly routed to Hyp mode, as described in *Asynchronous exception routing controls* on page B1-1174.
  - A synchronous external abort, Alignment fault, Undefined Instruction exception, or Supervisor Call exception taken from the Non-secure PL0 mode and explicitly routed to Hyp mode, as described in *Routing general exceptions to Hyp mode* on page B1-1191.

    Note

    A synchronous external abort can be routed to Hyp mode only if it not routed to Secure Monitor mode.

  - A debug exception that is explicitly routed to Hyp mode as described in *Routing Debug exceptions to Hyp mode* on page B1-1193.

Note

The virtual exceptions cannot be taken to Hyp mode. They are always taken to a Non-secure PL1 mode.

Asynchronous exception routing controls

In an implementation that includes the Security Extensions, the following bits in the SCR control the routing of asynchronous exceptions, and also the routing of synchronous external aborts:

SCR.EA When this bit is set to 1, any external abort is taken to Secure Monitor mode.

Note

- Unlike other controls described in this section, SCR.EA controls the routing of both synchronous and asynchronous external aborts.
- The other classes of abort cannot be routed to Monitor mode. For more information about the classification of aborts, see *VMSA memory aborts* on page B3-1395 or *PMSA memory aborts* on page B5-1763.

SCR.FIQ When this bit is set to 1, any FIQ exception is taken to Secure Monitor mode.

SCR.IRQ When this bit is set to 1, any IRQ exception is taken to Secure Monitor mode.

Only Secure software can change the values of these bits.

In an implementation that includes the Virtualization Extensions, the following bits in the HCR route asynchronous exceptions to Hyp mode, for exceptions that are both:

- taken from a Non-secure PL1 or PL0 mode
- not configured, by the SCR.{EA, FIQ, IRQ} controls, to be taken to Secure Monitor mode.

HCR.AMO If SCR.EA is set to 0, when this bit is set to 1, an asynchronous external abort taken from a Non-secure PL1 or PL0 mode is taken to Hyp mode, instead of to Non-secure Abort mode.

HCR.FMO If SCR.FIQ is set to 0, when this bit is set to 1, an FIQ exception taken from a Non-secure PL1 or PL0 mode is taken to Hyp mode, instead of to Non-secure FIQ mode.

HCR.IMO If SCR.IRQ is set to 0, when this bit is set to 1, an IRQ exceptions taken from a Non-secure PL1 or PL0 mode is taken to Hyp mode, instead of to Non-secure IRQ mode.

Only software executing in Hyp mode, or Secure software executing in Monitor mode when SCR.NS is set to 1, can change the values of these bits.

See also *Summaries of asynchronous exception behavior* on page B1-1185.

The HCR.{AMO, FMO, IMO} bits also affect the masking of asynchronous exceptions in Non-secure state, as described in *Asynchronous exception masking* on page B1-1183.

The SCR.{EA, FIQ, IRQ} and HCR.{AMO, FMO, IMO} bits have no effect on the routing of Virtual Abort, Virtual FIQ, and Virtual IRQ exceptions.

Summary of the possible modes for taking each exception

The following subsections describe the modes to which each exception can be taken:

- *Determining the mode to which the Undefined Instruction exception is taken* on page B1-1175
- *Determining the mode to which the Supervisor Call exception is taken* on page B1-1176
- *The mode to which the Secure Monitor Call exception is taken* on page B1-1176
- *The mode to which the Hypervisor Call exception is taken* on page B1-1176
- *The mode to which the Hyp Trap exception is taken* on page B1-1177
- *Determining the mode to which the Prefetch Abort exception is taken* on page B1-1177
- *Determining the mode to which the Data Abort exception is taken* on page B1-1178

- *The mode to which the Virtual Abort exception is taken* on page B1-1179
- *Determining the mode to which the IRQ exception is taken* on page B1-1179
- *The mode to which the Virtual IRQ exception is taken* on page B1-1179
- *Determining the mode to which the FIQ exception is taken* on page B1-1180
- *The mode to which the Virtual FIQ exception is taken* on page B1-1180.

These descriptions also show the vector offset for the exception entry for each mode.

For more information about:

- vector offsets, see *Exception vectors and the exception base address* on page B1-1164
- the routing of external aborts, IRQ and FIQ exceptions, and the virtual exceptions, see *Asynchronous exception routing controls* on page B1-1174.

Determining the mode to which the Undefined Instruction exception is taken

Figure B1-3 shows how the implementation, state, and configuration options determine the mode to which an Undefined Instruction exception is taken.

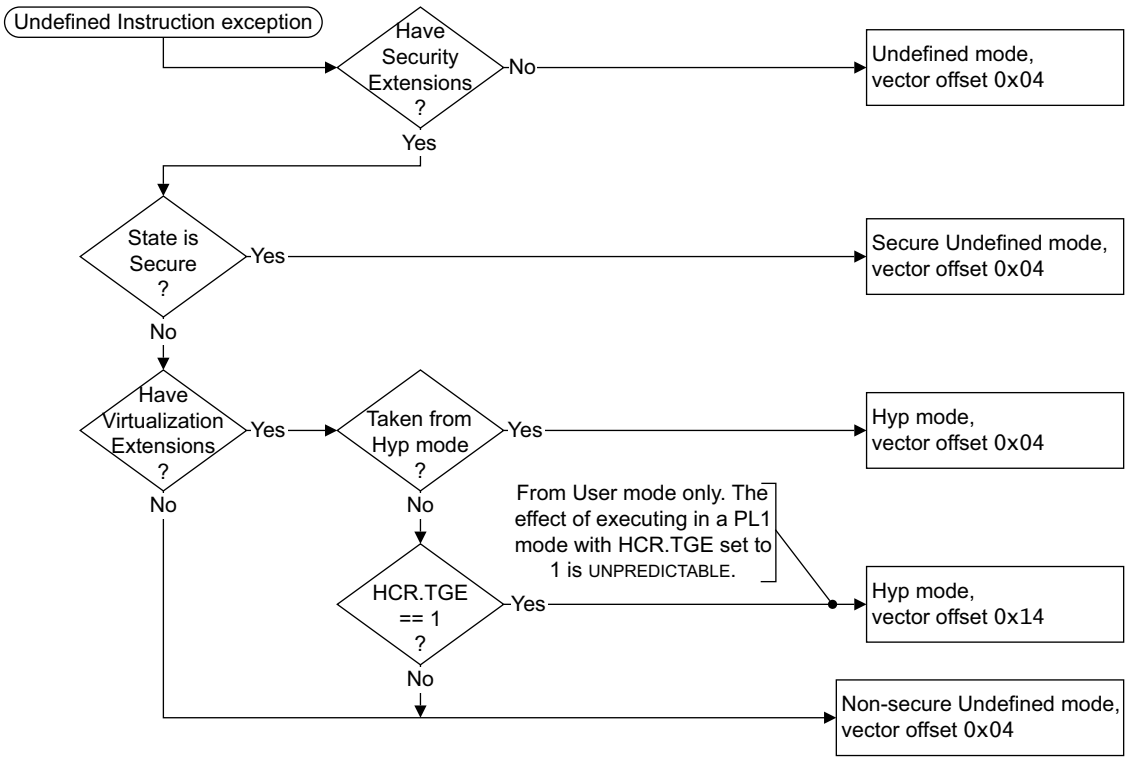

Figure B1-3 The mode the Undefined Instruction exception is taken to

Determining the mode to which the Supervisor Call exception is taken

Figure B1-4 shows how the implementation, state, and configuration options determine the mode to which a Supervisor Call exception is taken.

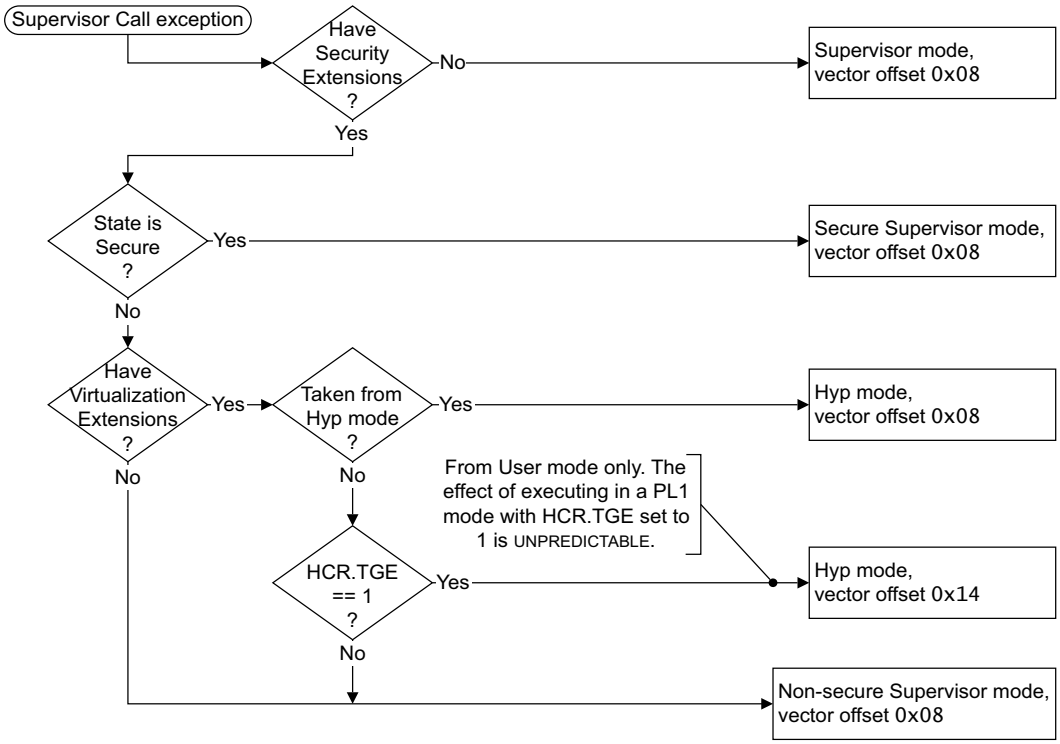

Figure B1-4 The mode the Supervisor Call exception is taken to

The mode to which the Secure Monitor Call exception is taken

The Secure Monitor Call exception is supported only as part of the Security Extensions. A Secure Monitor Call exception is taken to Monitor mode, using vector offset `0x08` from the Monitor exception base address.

Note

An `SMC` instruction that is trapped to Hyp mode because HCR.TSC is set to 1 generates a Hyp Trap exception, see *The mode to which the Hyp Trap exception is taken* on page B1-1177.

The mode to which the Hypervisor Call exception is taken

The Hypervisor Call exception is supported only as part of the Virtualization Extensions. A Hypervisor Call exception is taken to Hyp mode, using a vector offset that depends on the mode from which the exception is taken, as Figure B1-5 shows. This offset is from the Hyp exception base address.

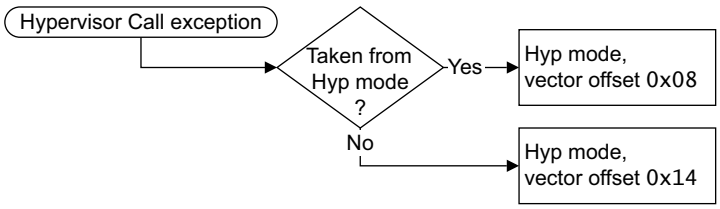

Figure B1-5 The mode the Hypervisor Call exception is taken to

The mode to which the Hyp Trap exception is taken

The Hyp Trap exception is supported only as part of the Virtualization Extensions. A Hyp Trap exception is taken to Hyp mode, using a vector offset of `0x14` from the Hyp exception base address.

Determining the mode to which the Prefetch Abort exception is taken

Figure B1-6 shows how the implementation, state, and configuration options determine the mode to which a Prefetch Abort exception is taken.

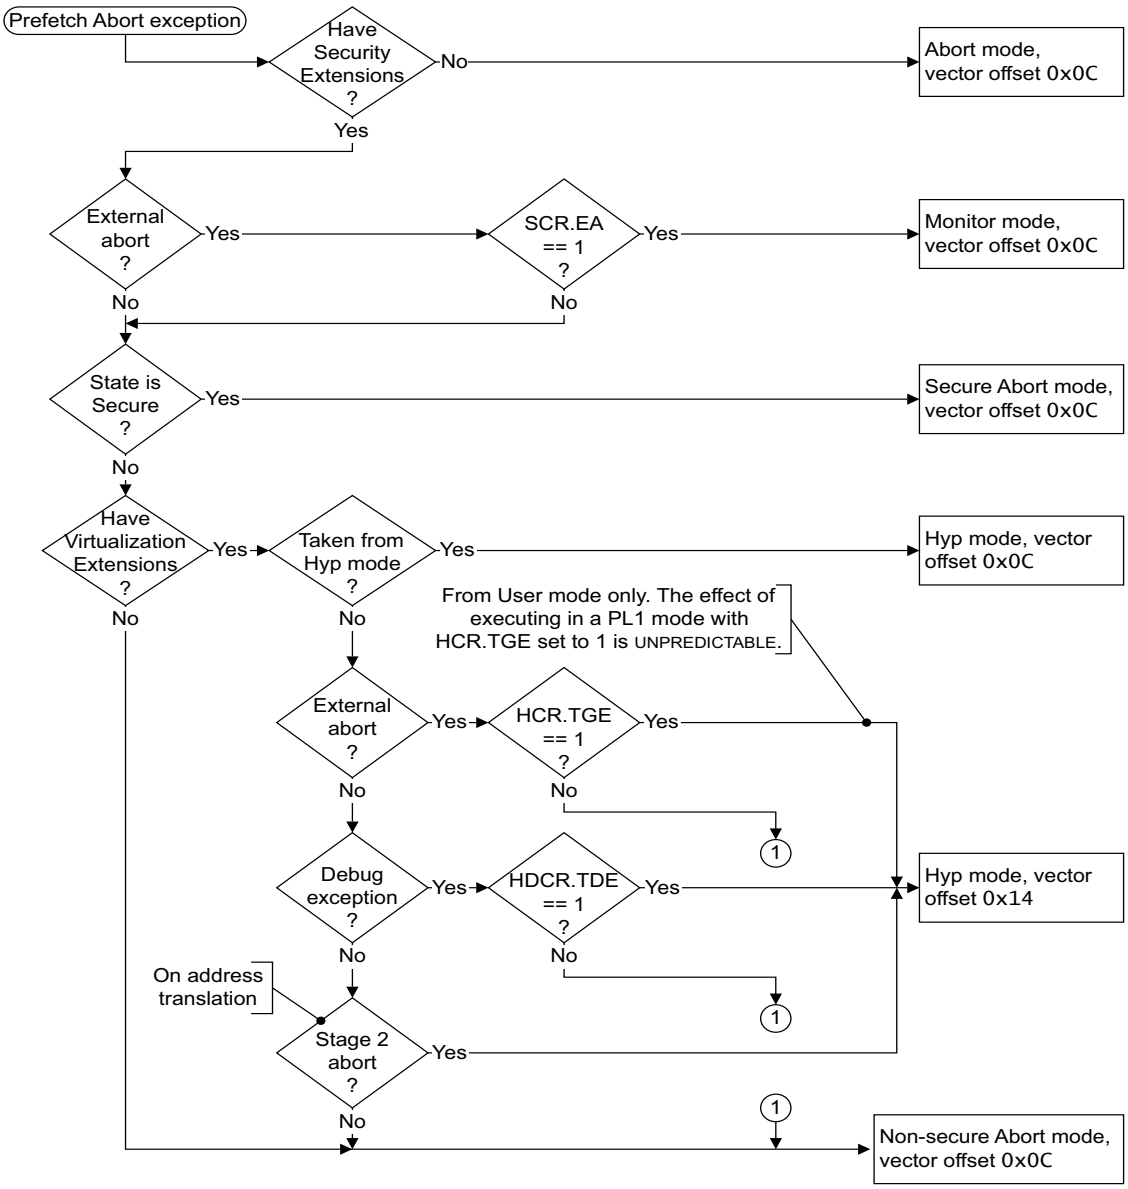

Figure B1-6 The mode the Prefetch Abort exception is taken to

Determining the mode to which the Data Abort exception is taken

Figure B1-7 shows how the implementation, state, and configuration options determine the mode to which a Data Abort exception is taken.

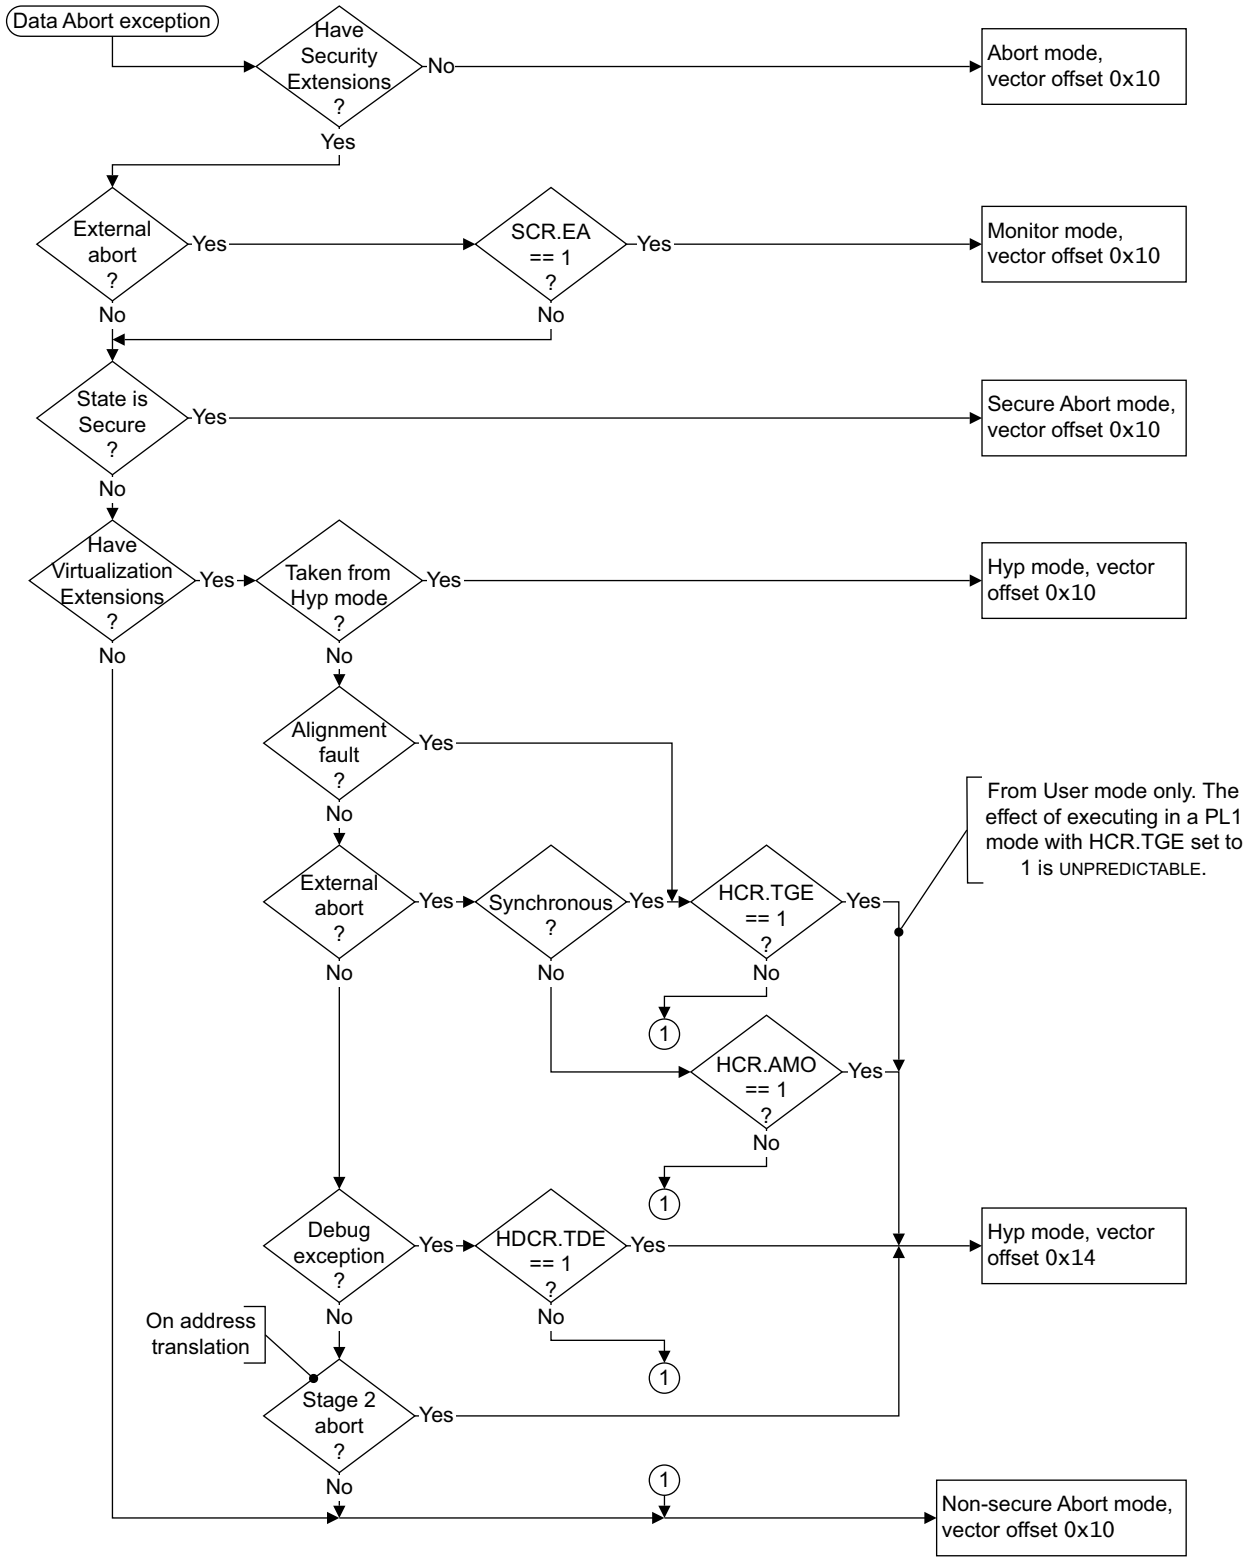

Figure B1-7 The mode the Data Abort exception is taken to

The mode to which the Virtual Abort exception is taken

The Virtual Abort exception is supported only as part of the Virtualization Extensions. A Virtual Abort exception is taken from a Non-secure PL1 or PL0 mode, and is taken to Non-secure Abort mode, using a vector offset of `0x10` from the Non-secure exception base address.

For more information about this exception see *Virtual exceptions in the Virtualization Extensions* on page B1-1196.

Determining the mode to which the IRQ exception is taken

Figure B1-8 shows how the implementation, state, and configuration options determine the mode to which an IRQ exception is taken.

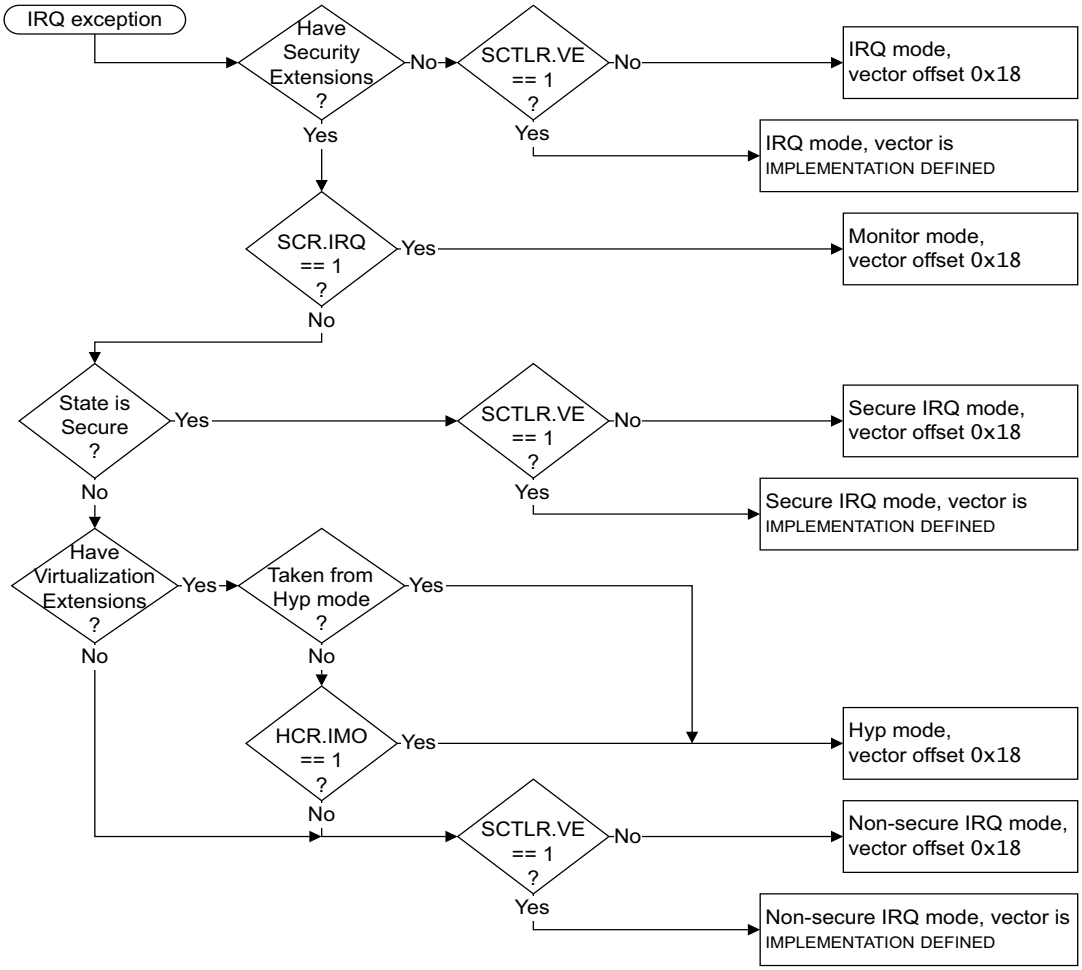

Figure B1-8 The mode the IRQ exception is taken to

The mode to which the Virtual IRQ exception is taken

The Virtual IRQ exception is supported only as part of the Virtualization Extensions. A Virtual IRQ exception is taken from a Non-secure PL1 or PL0 mode, and is taken to Non-secure IRQ mode, using a vector offset of `0x18` from the Non-secure exception base address.

For more information about this exception see *Virtual exceptions in the Virtualization Extensions* on page B1-1196.

Determining the mode to which the FIQ exception is taken

Figure B1-8 on page B1-1179 shows how the implementation, state, and configuration options determine the mode to which an FIQ exception is taken.

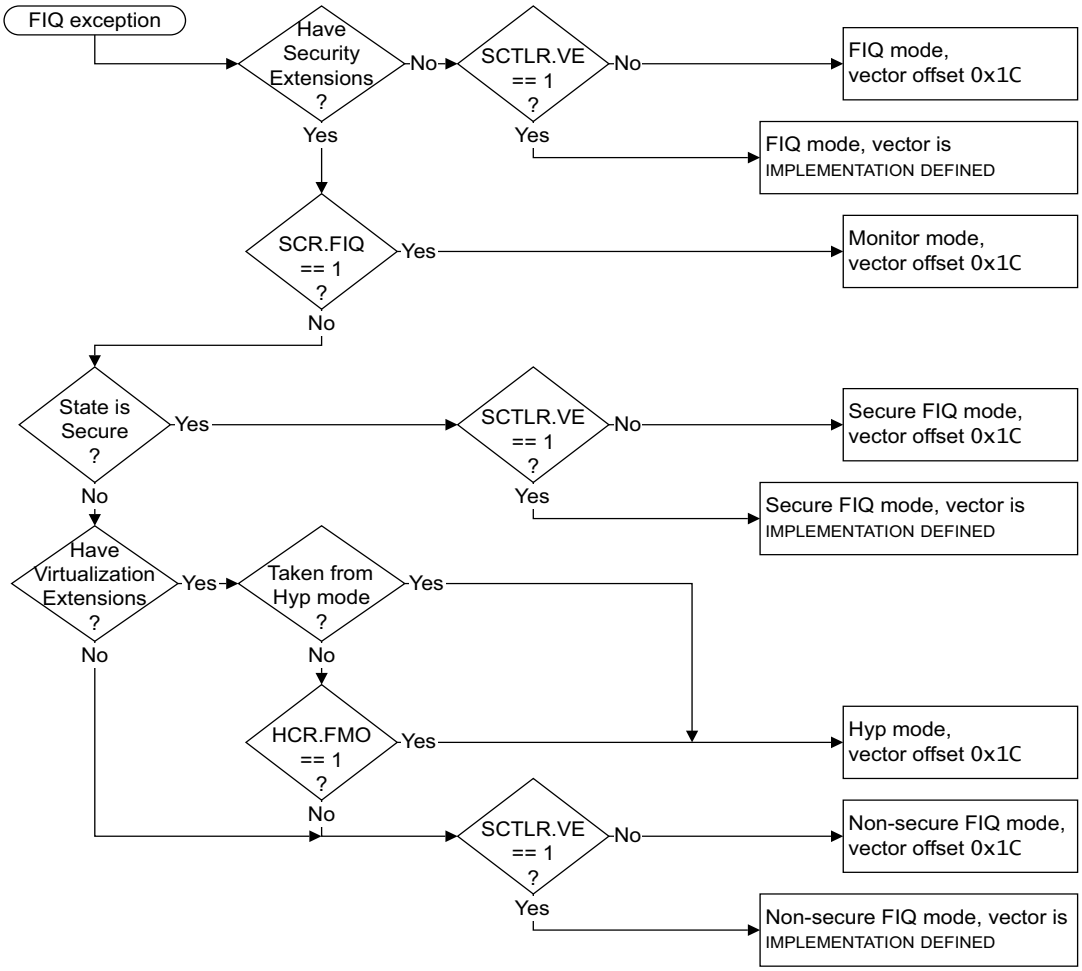

Figure B1-9 The mode the FIQ exception is taken to

The mode to which the Virtual FIQ exception is taken

The Virtual FIQ exception is supported only as part of the Virtualization Extensions. A Virtual FIQ exception is taken from a Non-secure PL1 or PL0 mode, and is taken to Non-secure FIQ mode, using a vector offset of `0x1C` from the Non-secure exception base address.

For more information about this exception see *Virtual exceptions in the Virtualization Extensions* on page B1-1196.

B1.8.5 Processor state on exception entry

The description of each exception includes a pseudocode description of entry to that exception, as Table B1-5 on page B1-1170 shows. The following sections describe the processor state changes on entering an exception, for different processor implementations and operating states. However, you must always see the exception entry pseudocode for a full description of the state changes on exception entry:

- *Instruction set state on exception entry*
- *CPSR.E bit value on exception entry*
- *CPSR.{A, I, F, M} values on exception entry* on page B1-1182.

Instruction set state on exception entry

Exception handlers always execute in either Thumb state or ARM state, as Table B1-8 shows. On exception entry, CPSR.{T, J} are set to the values shown, with the CPSR.T value determined by SCTLR.TE or HSCTLR.TE, depending on the mode the exception is taken to:

Table B1-8 CPSR.J and CPSR.T bit values on exception entry

Exception mode	HSCTLR.TE	SCTLR.TE	CPSR.J	CPSR.T	Exception handler state
Secure or Non-secure PL1	x	0	0	0	ARM
		1	0	1	Thumb
Hyp	0	x	0	0	ARM
	1	x	0	1	Thumb

When an implementation includes the Security Extensions, SCTLR is Banked for Secure and Non-secure states, and therefore the TE bit value might be different for Secure and Non-secure states. For an exception taken to a Secure or Non-secure PL1 mode, the SCTLR.TE bit for the security state to which the exception is taken determines the instruction set state for the exception handler. This means the PL1 exception handlers might run in different instruction set states, depending on the security state.

CPSR.E bit value on exception entry

The CPSR.E bit controls the load and store endianness for data handling. On exception entry, this bit is set as Table B1-9 shows:

Table B1-9 CPSR.E bit value on exception entry

Exception mode	HSCTLR.EE	SCTLR.EE	Endianness for data loads and stores	CPSR.E
Secure or Non-secure PL1	x	0	Little-endian	0
		1	Big-endian	1
Hyp	0	x	Little-endian	0
	1	x	Big-endian	1

For more information, see the bit description in *Format of the CPSR and SPSRs* on page B1-1148.

CPSR.{A, I, F, M} values on exception entry

On exception entry, CPSR.M is set to the value for the mode to which the exception is taken, as described in *Processor mode for taking exceptions* on page B1-1172.

Table B1-10 shows the cases where CPSR.{A, I, F} bits are set to 1 on an exception entry, and how this depends on the mode and security state to which an exception is taken. If the table entry for a particular mode and security state does not define a value for a CPSR.{A, I, F} bit then that bit is unchanged by the exception entry. In this table:

- The *Exception mode* column is the mode to which the exception is taken.
- The *Non-secure, no Virtualization Extensions* column applies to exceptions taken to Non-secure state in an implementation that includes the Security Extensions but not the Virtualization Extensions.
- The *All others* column applies to:
  - implementations that do not include the Security Extensions
  - exceptions taken to Secure state
  - exceptions taken to Non-secure state in an implementation that includes the Virtualization Extensions.

Table B1-10 CPSR.{A, I, F} values on exception entry

Exception mode	Security state and implementation	
	Non-secure, no Virtualization Extensions	All others
Hyp	-	If SCR.EA==0 then CPSR.A is set to 1 If SCR.IRQ==0 then CPSR.I is set to 1 If SCR.FIQ==0 then CPSR.F is set to 1
Monitor	-	CPSR.A is set to 1 CPSR.I is set to 1 CPSR.F is set to 1
FIQ	If SCR.AW==1 then CPSR.A is set to 1 CPSR.I is set to 1 If SCR.FW==1 then CPSR.F is set to 1	CPSR.A is set to 1 CPSR.I is set to 1 CPSR.F is set to 1
IRQ, Abort	If SCR.AW==1 then CPSR.A is set to 1 CPSR.I is set to 1	CPSR.A is set to 1 CPSR.I is set to 1
Undefined, Supervisor	CPSR.I is set to 1	CPSR.I is set to 1

Note

Compared to an implementation that includes only the Security Extensions, implementing the Virtualization Extensions changes both the effects of the SCR.{AW, FW} bits and the interpretation of the CPSR.{A, F} bits. *Asynchronous exception masking* on page B1-1183 summarizes the behavior for both of these implementation options.

B1.8.6 Asynchronous exception masking

The CPSR.{A, I, F} bits can mask the corresponding exceptions, as follows:

- CPSR.A can mask asynchronous aborts
- CPSR.I can mask IRQ exceptions
- CPSR.F can mask FIQ exceptions.

In an ARMv7 implementation that does not include the Security Extensions, setting one of these bits to 1 masks the corresponding exception, meaning the exception cannot be taken.

In an implementation that includes the Security Extensions, the SCR.{AW, FW} bits provide a mechanism to prevent use of the CPSR.{A, F} mask bits by Non-secure software. In an implementation that includes the Virtualization Extensions:

- HCR.{AMO, FMO} modify this mechanism
- HCR.IMO can prevent the masking, by CPSR.I, of IRQs taken from Non-secure state.

This means the asynchronous exception masking mechanism is as follows:

Implementation that includes the Security Extensions but not the Virtualization Extensions

When an SCR.{AW, FW} bit is set to 0, Non-secure software cannot update the corresponding CPSR bit. This means:

- when SCR.AW is set to 0, CPSR.A cannot be updated in Non-secure state
- when SCR.FW is set to 0, CPSR.F cannot be updated in Non-secure state.

Note

There is no control of updates to CPSR.I. CPSR.I can be updated in either security state.

The CPSR.{A, I, F} bits mask the corresponding exceptions. This means:

- when CPSR.A is set to 1, asynchronous aborts are masked
- when CPSR.I is set to 1, IRQs are masked
- when CPSR.F is set to 1, FIQs are masked.

Implementation that includes the Security Extensions and the Virtualization Extensions

When an HCR.{AMO, IMO, FMO} mask override bit is set to 1, the value of the corresponding CPSR.{A, I, F} bit is ignored when both of the following apply:

- the exception is taken from Non-secure state
- either:
  - the corresponding SCR.{EA, IRQ, FIQ} bit routes the exception to Monitor mode
  - the exception is taken from a Non-secure mode other than Hyp mode.

In addition, when an SCR.{AW, FW} bit is set to 0, the value of the corresponding CPSR.{A, F} bit is ignored when all of the following apply:

- the exception is taken from Non-secure state
- the corresponding SCR.{EA, FIQ} bit routes the exception to Monitor mode
- the corresponding HCR.{AMO, FMO} mask override bit is set to 0.

This means that the controls on each of the CPSR mask bits, and the effect of those bits, are as shown in the following tables.

Table B1-11 shows the controls of the masking of asynchronous exceptions by CPSR.A.

Table B1-11 Control of masking by CPSR.A

Security state	HCR.AMO	SCR.EA	SCR.AW	Mode	CPSR.A
Secure	x	x	x	x	Masks asynchronous aborts, when set to 1
Non-secure	0	0	x	x	Masks asynchronous aborts, when set to 1
		1	0	x	Ignored
			1	x	Masks asynchronous aborts, when set to 1
	1	x	x	Not Hyp	Ignored
		0	x	Hyp	Masks asynchronous aborts, when set to 1
		1	x	x	Ignored

Table B1-12 shows the controls of the masking of FIQ exceptions by CPSR.F:

Table B1-12 Control of masking by CPSR.I

Security state	HCR.IMO	SCR.IRQ	Mode	CPSR.I
Secure	x	x	x	Masks IRQs, when set to 1
Non-secure	0	x	x	Masks IRQs, when set to 1
	1	x	Not Hyp	Ignored
		0	Hyp	Masks IRQs, when set to 1
		1	x	Ignored

Table B1-13 shows the controls of the masking of FIQ exceptions by CPSR.F:

Table B1-13 Control of masking by CPSR.F

Security state	HCR.FMO	SCR.FIQ	SCR.FW	Mode	CPSR.F
Secure	x	x	x	x	Masks FIQs, when set to 1
Non-secure	0	0	x	x	Masks FIQs, when set to 1
		1	0	x	Ignored
			1	x	Masks FIQs, when set to 1
	1	x	x	Not Hyp	Ignored
		0	x	Hyp	Masks FIQs, when set to 1
		1	x	x	Ignored

The values of SCR.{AW, FW} do not affect whether CPSR.{A, F} can be updated in Non-secure state.

Mask override bits in the Virtualization Extensions on page B1-1185 gives more information about the HCR.{AMO, IMO, FMO} bits.

Mask override bits in the Virtualization Extensions

The Virtualization Extensions add a set of mask override bits to the HCR, that affect both:

- the masking of asynchronous exceptions taken from Non-secure state
- the enabling of the corresponding virtual exceptions.

These mask bits and their effects are:

- HCR.AMO can affect the masking of asynchronous aborts, and the enabling of Virtual Abort exceptions
- HCR.IMO can affect the masking of IRQ exceptions, and the enabling of Virtual IRQ exceptions
- HCR.FMO can affect the masking of FIQ exceptions, and the enabling of Virtual FIQ exceptions.

These bits can also affect the routing of the corresponding physical exceptions, see *Asynchronous exception routing controls* on page B1-1174.

The HCR mask override bits have no effect on exceptions taken to Secure state.

If an HCR mask override bit is set to 1, when the processor is in Non-secure state and not in Hyp mode:

- If the corresponding physical exception is not routed to Monitor mode, the physical exception is taken to Hyp mode.
- When the corresponding CPSR mask bit is set to 1 it:
  - masks the corresponding virtual exception
  - does not mask the corresponding physical exception.
- If the corresponding virtual exception bit in the HCR is set to 1, and the corresponding CPSR mask bit is not set to 1, the virtual exception is signaled to the processor.

When the processor is in Hyp mode, if an HCR mask override bit is set to 1 the corresponding CPSR mask bit cannot mask the corresponding physical exception if that exception is routed to Monitor mode.

Note

When the processor is in Hyp mode:

- physical asynchronous exceptions that are not routed to Monitor mode are taken to Hyp mode
- virtual exceptions are not signaled to the processor.

B1.8.7 Summaries of asynchronous exception behavior

In an ARMv7 implementation that does not include the Security Extensions, the asynchronous exceptions behave as follows:

- an asynchronous abort is taken to Abort mode
