Artificial Intelligence I	Knowledge representation and reasoning using FOL
Dr Sean Holden	We now look at how an agent might <i>represent</i> knowledge about its environment using first order logic (FOL), and <i>reason</i> with this knowledge to achieve its goals.
	Aims:
Notes on knowledge representation and reasoning using first-order logic (FOL)	• To show how FOL can be used to <i>represent knowledge</i> about an environment in the form of both <i>background knowledge</i> and <i>knowledge derived from percepts</i> .
	• To show how this knowledge can be used to <i>derive non-perceived knowledge</i> about the environment using a <i>theorem prover</i> .
	• To introduce the <i>situation calculus</i> and demonstrate its applica- tion in a simple environment as a means by which an agent can work out what to do next.
Copyright © Sean Holden 2002-2010.	
Interesting reading	Knowledge representation and reasoning
Reading: Russell and Norvig, chapters 7 to 10.	Earlier in the course we looked at what an <i>agent</i> should be able to do.
Knowledge representation based on logic is a vast subject and can't be covered in full in the lectures. In particular:	It seems that all of us—and all intelligent agents—should use <i>logical</i> reasoning to help us interact successfully with the world. Any intelligent agent should:
• Techniques for representing <i>further kinds of knowledge</i> .	
• Techniques for moving beyond the idea of a <i>situation</i> .	• Possess knowledge about the environment and about how its actions affect the environment.
<ul><li> Reasoning systems based on categories.</li><li> Reasoning systems using default information.</li></ul>	• Use some form of <i>logical reasoning</i> to <i>maintain</i> its knowledge as <i>percepts</i> arrive.
• Truth maintenance systems.	<ul> <li>Use some form of <i>logical reasoning</i> to <i>deduce actions</i> to perform in order to achieve <i>goals</i>.</li> </ul>
Happy reading :-)	

## Knowledge representation and reasoning

This raises some important questions:

- How do we describe the current state of the world?
- How do we infer from our percepts, knowledge of unseen parts of the world?
- How does the world change as time passes?
- How does the world stay the same as time passes? (The *frame problem*.)
- How do we know the effects of our actions? (The qualification and ramification problems.)

We'll now look at one way of answering some of these questions.

## Logic for knowledge representation

FOL (arguably?) seems to provide a good way in which to represent the required kinds of knowledge:

- It is *expressive*—anything you can program can be expressed.
- It is concise.
- It is unambiguous
- It can be adapted to different contexts.
- It has an *inference procedure*, although a semidecidable one.

In addition is has a well-defined syntax and semantics.

## Logic for knowledge representation

*Problem:* it's quite easy to talk about things like *set theory* using FOL. For example, we can easily write axioms like

 $\forall S \ . \ \forall S' \ . \ ((\forall x \ . \ (x \in S \Leftrightarrow x \in S')) \Rightarrow S = S')$ 

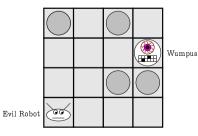

But how would we go about representing the proposition that if you have a bucket of water and throw it at your friend they will get wet, have a bump on their head from being hit by a bucket, and the bucket will now be empty and dented?

More importantly, how could this be represented within a wider framework for reasoning about the world?

It's time to introduce my friend, The Wumpus...

## Wumpus world

As a simple test scenario for a knowledge-based agent we will make use of the *Wumpus World*.

The Wumpus World is a 4 by 4 grid-based cave.

EVIL ROBOT wants to enter the cave, find some gold, and get out again un-scathed.

#### Wumpus world

The rules of Wumpus World:

- Unfortunately the cave contains a number of pits, which EVIL ROBOT can fall into. Eventually his batteries will fail, and that's the end of him.
- The cave also contains the Wumpus, who is armed with state of the art *Evil Robot Obliteration Technology*.
- The Wumpus itself knows where the pits are and never falls into one.

Wumpus world

So we have:

Percepts: stench, breeze, glitter, bump, scream.

Actions: forward, turnLeft, turnRight, grab, release, shoot, climb.

Of course, our aim now is *not* just to design an agent that can perform well in a single cave layout.

We want to design an agent that can *usually* perform well *regardless* of the layout of the cave.

#### Wumpus world

**EVIL ROBOT** can move around the cave at will and can perceive the following:

- In a position adjacent to the Wumpus, a stench is perceived. (Wumpuses are famed for their *lack of personal hygiene*.)
- In a position adjacent to a pit, a *breeze* is perceived.
- In the position where the gold is, a glitter is perceived.
- On trying to move into a wall, a *bump* is perceived.
- On killing the Wumpus a *scream* is perceived.

In addition, EVIL ROBOT has a single arrow, with which to try to kill the Wumpus.

"Adjacent" in the following does *not* include diagonals.

#### Some nomenclature

The choice of knowledge representation language tends to lead to two important commitments:

- Ontological commitments: what does the world consist of?
- *Epistemological commitments*: what are the allowable states of knowledge?

Propositional logic is useful for introducing some fundamental ideas, but its ontological commitment—that the world consists of facts sometimes makes it too limited for further use.

FOL has a different ontological commitment—the world consists of *facts*, *objects* and *relations*.

## Logic for knowledge representation

The fundamental aim is to construct a *knowledge base* KB containing a *collection of statements* about the world—expressed in FOL such that *useful things can be derived* from it.

Our central aim is to generate sentences that are *true*, if *the sentences in the* KB *are true*.

This process is based on concepts familiar from your introductory logic courses:

- Entailment:  $KB \models \alpha$  means that the KB entails  $\alpha$ .
- Proof:  $KB \vdash_i \alpha$  means that  $\alpha$  is derived from the KB using i. If i is sound then we have a proof.
- i is sound if it can generate only entailed  $\alpha$ .
- i is complete if it can find a proof for any entailed  $\alpha$ .

#### Example: Prolog

You have by now learned a little about programming in *Prolog*. For example:

concat([],L,L).
concat([H|T],L,[H|L2]) :- concat(T,L,L2).

is a program to concatenate two lists. The query

concat([1,2,3],[4,5],X).

results in

X = [1, 2, 3, 4, 5].

What's happening here? Well, Prolog is just a more limited form of FOL so...

## Example: Prolog

... we are in fact doing inference from a KB:

- The Prolog programme itself is the KB. It expresses some knowledge about lists.
- The query is expressed in such a way as to derive some new knowledge.

How does this relate to full FOL? First of all the list notation is nothing but *syntactic sugar*. It can be removed: we define a constant called empty and a function called cons.

Now [1,2,3] just means cons(1, cons(2, cons(3, empty)))) which is a term in FOL.

I will assume the use of the syntactic sugar for lists from now on.

## $Prolog \ and \ FOL$

The program when expressed in FOL, says

 $\forall x. \texttt{concat}(\texttt{empty}, x, x) \land$ 

 $\forall h, t, l_1, l_2. \texttt{concat}(t, l_1, l_2) \Longrightarrow \texttt{concat}(\texttt{cons}(h, t), l_1, \texttt{cons}(h, l_2))$ 

The rule is simple—given a Prolog program:

- Universally quantify all the unbound variables in each line of the program and ...
- ... form the conjunction of the results.

If the universally quantified lines are  $L_1,L_2,\ldots,L_n$  then the Prolog programme corresponds to the KB

$$KB = L_1 \wedge L_2 \wedge \cdots \wedge L_n$$

Now, what does the query mean?

## Prolog and FOL

When you give the query

concat([1,2,3],[4,5],X).

to Prolog it responds by trying to prove the following statement

 $\texttt{KB} \Longrightarrow \exists \texttt{x}.\texttt{concat}([1,2,3],[4,5],\texttt{x})$ 

So: it tries to prove that the KB *implies the query*, and variables in the query are existentially quantified.

When a proof is found, it supplies a value for x that makes the inference true.

## Prolog and FOL

Prolog differs from FOL in that, amongst other things:

• It restricts you to using Horn clauses.

• Its inference procedure is not a *full-blown proof procedure*.

• It does not deal with *negation* correctly.

However the central idea also works for full-blown theorem provers.

If you want to experiment, you can obtain Prover9 from

http://www.cs.unm.edu/~mccune/mace4/

We'll see a brief example now, and a more extensive example of its use later, time permitting...

Prolog and FOL

Expressed in Prover9, the above Prolog program and query look like this:

set(prolog\_style\_variables).

% This is the translated Prolog program for list concatenation. % Prover9 has its own syntactic sugar for lists.

formulas(assumptions).
 concat([], L, L).
 concat(T, L, L2) -> concat([H:T], L, [H:L2]).
end\_of\_list.

% This is the query.

formulas(goals).
 exists X concat([1, 2, 3], [4, 5], X).
end\_of\_list.

Note: it is assumed that unbound variables are universally quantified. Prolog and FOL

You can try to infer a proof using

prover9 -f file.in

and the result is (in addition to a lot of other information):

1 concat(T,L,L2) -> concat([H:T],L,[H:L2]) # label(non\_clause). [assumption]. 2 (exists X concat([1,2,3],[4,5],X)) # label(non\_clause) # label(goal). [goal]. 3 concat([],A,A). [assumption]. 4 -concat(A,B,C) | concat([D:A],B,[D:C]). [clausify(1)]. 5 -concat([1,2,3],[4,5],A). [deny(2)]. 6 concat([A],B,[A:B]). [ur(4,a,3,a)]. 7 -concat([2,3],[4,5],A). [resolve(5,a,4,b)]. 8 concat([A,B],C,[A,B:C]). [ur(4,a,6,a)]. 9 \$F. [resolve(8,a,7,a)].

This shows that a proof is found but doesn't explicitly give a value for X—we'll see how to extract that later...

## The fundamental idea

So the basic idea is: build a KB that encodes knowledge about the world, the effects of actions and so on.

The KB is a conjunction of pieces of knowledge, such that:

• A query regarding what our agent should do can be posed in the form

∃actionList.Goal(... actionList ...)

• Proving that

 $KB \implies \exists actionList.Goal(... actionList ...)$ 

instantiates actionList to an *actual list of actions* that will achieve a goal represented by the Goal predicate.

We sometimes use the notation ask and tell to refer to querying and  $adding \ to \ the \ KB.$ 

## Using FOL in AI: the triumphant return of the Wumpus

We want to be able to *speculate* about the past and about *possible futures*. So:

- We include *situations* in the logical language used by our KB.
- We include *axioms* in our KB that relate to situations.

This gives rise to situation calculus.

## Situation calculus

In situation calculus:

- The world consists of sequences of *situations*.
- Over time, an agent moves from one situation to another.
- Situations are changed as a result of *actions*.

In Wumpus World the actions are: forward, shoot, grab, climb, release, turnRight, turnLeft.

• A *situation argument* is added to items that can change over time. For example

At(location, s)

Items that can change over time are called *fluents*.

• A situation argument is not needed for things that don't change. These are sometimes referred to as *eternal* or *atemporal*. Representing change as a result of actions

Situation calculus uses a function

result(action, s)

to denote the new situation arising as a result of performing the specified action in the specified situation.

```
\begin{aligned} & \text{result}(\texttt{grab}, s_0) = s_1 \\ & \text{result}(\texttt{turnLeft}, s_1) = s_2 \\ & \text{result}(\texttt{shoot}, s_2) = s_3 \\ & \text{result}(\texttt{forward}, s_3) = s_4 \\ & \vdots \end{aligned}
```

## Axioms I: possibility axioms

The first kind of axiom we need in a KB specifies when particular actions are possible.

We introduce a predicate

## Poss(action, s)

denoting that an action can be performed in situation s.

We then need a *possibility axiom* for each action. For example:

 $At(l,s) \land Available(gold, l, s) \Longrightarrow Poss(grab, s)$ 

Remember that unbound variables are universally quantified.

## Axioms III: frame axioms

We need frame axioms to describe the way in which the world stays the same.

#### Example:

 $Have(o, s) \land$ 

 $\neg(a = \text{release} \land o = \text{gold}) \land \neg(a = \text{shoot} \land o = \text{arrow})$  $\implies \text{Have}(o, \text{result}(a, s))$ 

describes the effect of having something and not discarding it.

In a more general setting such an axiom might well look different. For example

```
\neg Have(o, s) \land
(a \neq grab(o) \lor \neg (Available(o, s) \land Portable(o)))
\implies \neg Have(o, result(a, s))
```

describes the effect of not having something and not picking it up.

#### Axioms II: effect axioms

Given that an action results in a new situation, we can introduce *effect axioms* to specify the properties of the new situation.

For example, to keep track of whether EVIL ROBOT has the gold we need *effect axioms* to describe the effect of picking it up:

 $Poss(grab, s) \Longrightarrow Have(gold, result(grab, s))$ 

Effect axioms describe the way in which the world *changes*.

We would probably also include

 $\neg$ Have(gold, s<sub>0</sub>)

in the KB, where  $s_0$  is the starting state.

Important: we are describing what is true in the situation that results from performing an action in a given situation.

## The frame problem

The *frame problem* has historically been a major issue.

Representational frame problem: a large number of frame axioms are required to represent the many things in the world which will not change as the result of an action.

We will see how to solve this in a moment.

Inferential frame problem: when reasoning about a sequence of situations, all the unchanged properties still need to be carried through all the steps.

This can be alleviated using *planning systems* that allow us to reason efficiently when actions change only a small part of the world. There are also other remedies, which we will not cover.

#### Successor-state axioms

Effect axioms and frame axioms can be combined into *successor-state axioms*.

One is needed for each predicate that can change over time.

Action a is possible  $\Longrightarrow$ 

(true in new situation  $\iff$ (you did something to make it true  $\lor$ it was already true and you didn't make it false))

#### For example

 $\begin{array}{l} \operatorname{Poss}(a,s) \Longrightarrow \\ (\operatorname{Have}(o,\operatorname{result}(a,s)) \iff ((a = \operatorname{grab} \land \operatorname{Available}(o,s)) \lor \\ (\operatorname{Have}(o,s) \land \neg (a = \operatorname{release} \land o = \operatorname{gold}) \land \\ \neg (a = \operatorname{shoot} \land o = \operatorname{arrow})))) \end{array}$ 

## Knowing where you are

The concept of adjacency is very important in the Wumpus world

 $Adjacent(l_1, l_2) \iff \exists d \text{ forwardResult}(l_1, d) = l_2$ 

We also know that the cave is 4 by 4 and surrounded by walls

 $WallHere((x,y)) \iff (x = 0 \lor y = 0 \lor x = 5 \lor y = 5)$ 

It is only possible to change location by moving, and this only works if you're not facing a wall. So...

...we need a successor-state axiom:

 $\begin{array}{l} \operatorname{Poss}(a,s) \Longrightarrow \\ \operatorname{At}(l,\operatorname{result}(a,s)) \iff (l = \operatorname{goForward}(s) \\ \land a = \operatorname{forward} \\ \land \neg \operatorname{WallHere}(l)) \\ \lor (\operatorname{At}(l,s) \land a \neq \operatorname{forward}) \end{array}$ 

If  $s_0$  is the initial situation we know that

 $At((1, 1), s_0)$ 

I am *assuming* that we've added axioms allowing us to deal with the numbers 0 to 5 and pairs of such numbers. *(Exercise: do this.)* 

We need to keep track of what way we're facing. Say north is 0, south is 2, east is 1 and west is 3.

 $facing(s_0) = 0$ We need to know how motion affects location

$$\begin{split} & \text{forwardResult}((x,y),\texttt{north}) = (x,y+1) \\ & \text{forwardResult}((x,y),\texttt{east}) = (x+1,y) \end{split}$$

and

$$At(l, s) \Longrightarrow goForward(s) = forwardResult(l, facing(s))$$

## Knowing where you are

It is only possible to change orientation by turning. Again, we need a successor-state axiom

$$\begin{array}{l} \operatorname{Poss}(a,s) \Longrightarrow \\ \operatorname{facing}(\operatorname{result}(a,s)) = d \iff \\ (a = \operatorname{turnRight} \wedge d = \operatorname{mod}(\operatorname{facing}(s) + 1, 4)) \\ \vee (a = \operatorname{turnLeft} \wedge d = \operatorname{mod}(\operatorname{facing}(s) - 1, 4)) \\ \vee (\operatorname{facing}(s) = d \wedge a \neq \operatorname{turnRight} \wedge a \neq \operatorname{turnLeft}) \end{array}$$

and so on...

## The qualification and ramification problems

*Qualification problem*: we are in general never completely certain what conditions are required for an action to be effective.

Consider for example turning the key to start your car.

This will lead to problems if important conditions are omitted from axioms.

Ramification problem: actions tend to have implicit consequences that are large in number.

For example, if I pick up a sandwich in a dodgy sandwich shop, I will also be picking up all the bugs that live in it. I don't want to model this explicitly.

## Solving the ramification problem

The ramification problem can be solved by *modifying successor-state axioms*.

For example:

```
\begin{array}{l} \operatorname{Poss}(a,s) \Longrightarrow \\ (\operatorname{At}(o,l,\operatorname{result}(a,s)) \iff \\ (a = \operatorname{go}(l',l) \land \\ [o = \operatorname{robot} \lor \operatorname{Has}(\operatorname{robot},o,s)]) \lor \\ (\operatorname{At}(o,l,s) \land \\ [\neg \exists l'' . a = \operatorname{go}(l,l'') \land l \neq l'' \land \\ \{o = \operatorname{robot} \lor \operatorname{Has}(\operatorname{robot},o,s)\}])) \end{array}
```

describes the fact that anything  $\underline{\text{EVIL}}$   $\underline{\text{ROBOT}}$  is carrying moves around with him.

## Deducing properties of the world: causal rules

If you know where you are, then you can think about *places* rather than just *situations*.

 $Synchronic\ rules\ relate\ properties\ shared\ by\ a\ single\ state\ of\ the\ world.$ 

There are two kinds: *causal* and *diagnostic*.

Causal rules: some properties of the world will produce percepts.

 $WumpusAt(l_1) \land Adjacent(l_1, l_2) \Longrightarrow StenchAt(l_2)$ 

 $PitAt(l_1) \land Adjacent(l_1, l_2) \Longrightarrow BreezeAt(l_2)$ 

Systems reasoning with such rules are known as model-based reasoning systems.

## Deducing properties of the world: diagnostic rules

Diagnostic rules: infer properties of the world from percepts.

For example:

 $At(l,s) \land Breeze(s) \Longrightarrow BreezeAt(l)$ 

 $\mathsf{At}(\mathsf{l},s)\wedge\mathtt{Stench}(s)\Longrightarrow\mathtt{StenchAt}(\mathsf{l})$ 

These may not be very strong.

The difference between model-based and diagnostic reasoning can be important. For example, medical diagnosis can be done based on symptoms or based on a model of disease.

## General axioms for situations and objects

*Note*: in FOL, if we have two constants robot and gold then an interpretation is free to assign them to be the same thing.

This is not something we want to allow.

Unique names axioms state that each pair of distinct items in our model of the world must be different

```
robot \neq gold
robot \neq arrow
robot \neq wumpus
:
wumpus \neq gold
:
```

#### General axioms for situations and objects

Unique actions axioms state that actions must share this property, so for each pair of actions

 $go(l, l') \neq grab$  $go(l, l') \neq drop(o)$ :  $drop(o) \neq shoot$ :

and in addition we need to define equality for actions, so for each action  $= (1, 1') = = (1'', 1''') \iff (1 - 1'' \land 1' - 1''')$ 

$$go(l, l') = go(l'', l''') \iff l = l'' \land l' = drop(o) = drop(o') \iff o = o'$$

General axioms for situations and objects

The situations are *ordered* so

 $s_0 \neq result(a, s)$ 

and situations are distinct so

 $\operatorname{result}(a,s) = \operatorname{result}(a',s') \iff a = a' \wedge s = s'$ 

Strictly speaking we should be using a *many-sorted* version of FOL.

In such a system variables can be divided into *sorts* which are implicitly separate from one another.

#### <u>The start state</u>

Finally, we're going to need to specify what's true in the start state.

For example

```
At(robot, [1, 1], s_0)
At(wumpus, [3, 4], s_0)
Has(robot, arrow, s_0)
```

and so on.

## Sequences of situations

We know that the function result tells us about the situation resulting from performing an action in an earlier situation.

How can this help us find sequences of actions to get things done?

#### Define

 $\begin{array}{l} \text{Sequence}([],s,s')=s'=s\\ \text{Sequence}([a],s,s')=\text{Poss}(a,s)\wedge s'=\text{result}(a,s)\\ \text{Sequence}(a::as,s,s')=\exists t \text{ . Sequence}([a],s,t)\wedge \text{Sequence}(as,t,s') \end{array}$ 

To obtain a sequence of actions that achieves  $\operatorname{Goal}(s)$  we can use the query

 $\exists a \; \exists s \; . \; \texttt{Sequence}(a, s_0, s) \land \texttt{Goal}(s)$ 

## <u>Problems</u>

#### Paper 9, Question 8, 2003 - part 2

You wish to construct a robotic pet cat for the purposes of entertainment. One purpose of the cat is to scratch valuable objects when the owner is not present. Give a brief general description of *situation calculus* and describe how it might be used for knowledge representation by the robot. Include in your answer one example each of a *frame axiom*, an *effect axiom*, and a *successor-state axiom*, along with example definitions of suitable predicates and functions. [12 marks]

#### <u>Problems</u>

1. There have in fact been *two* queries suggested in the notes for obtaining a sequence of actions. The details for

 $\exists a \exists s . Sequence(a, s_0, s) \land Goal(s)$ 

were given on the last slide, but earlier in the notes the format

∃actionList.Goal(... actionList ...)

was suggested. Explain how this alternative form of query might be made to work.

- 2. Making correct use of the situation calculus, write the sentences in FOL required to implement the following actions in Wumpus World:
  - Climb
  - Shoot

## Knowledge representation and reasoning

It should be clear that generating sequences of actions by inference in FOL is highly non-trivial.

Ideally we'd like to maintain an *expressive* language while *restricting* it enough to be able to do inference *efficiently*.

Further aims:

- To give a brief introduction to *semantic networks* and *frames* for knowledge representation.
- To see how *inheritance* can be applied as a reasoning method.
- To look at the use of *rules* for knowledge representation, along with *forward chaining* and *backward chaining* for reasoning.

Further reading: The Essence of Artificial Intelligence, Alison Cawsey. Prentice Hall, 1998.

#### Frames and semantic networks

Frames and semantic networks represent knowledge in the form of *classes of objects* and *relationships between them*:

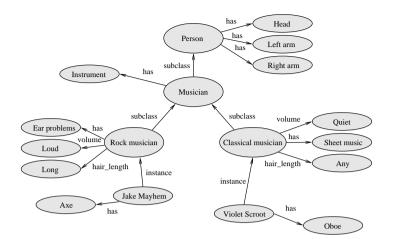

- The subclass and instance relationships are emphasised.
- We form *class hierarchies* in which *inheritance* is supported and provides the main *inference mechanism*.

As a result inference is quite limited.

We also need to be extremely careful about *semantics*.

The only major difference between the two ideas is notational.

# Example of a semantic network

#### <u>Frames</u>

Frames once again support inheritance through the *subclass relationship*.

#### Rock musician

subclass: Musician has: ear problems hairlength: long volume: loud

has, hairlength, volume *etc* are *slots*.

long, loud, instrument etc are slot values.

These are a direct predecessor of *object-oriented programming languages*.

#### <u>Defaults</u>

Both approaches to knowledge representation are able to incorporate *defaults*:

# Rock musician

loud

ear problems

has:

\* hairlength: long

\* volume:

subclass: Rock musician hairlength: short image: gothic

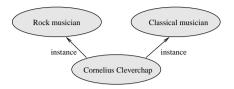

Dementia Evilperson

Starred slots are *typical values* associated with subclasses and instances, but *can be overridden*.

#### Other issues

#### Multiple inheritance

Both approaches can incorporate *multiple inheritance*, at a cost:

- What is hairlength for Cornelius if we're trying to use inheritance to establish it?
- This can be overcome initially by specifying which class is inherited from *in preference* when there's a conflict.
- But the problem is still not entirely solved—what if we want to prefer inheritance of some things from one class, but inheritance of others from a different one?

## Rule-based systems

A rule-based system requires three things:

1. A set of if-then rules. These denote specific pieces of knowledge about the world.

They should be interpreted similarly to logical implication.

Such rules denote *what to do* or *what can be inferred* under given circumstances.

- 2. A collection of *facts* denoting what the system regards as currently true about the world.
- 3. An interpreter able to apply the current rules in the light of the current facts.

- Slots and slot values can themselves be frames. For example Dementia may have an instrument slot with the value Electric harp, which itself may have properties described in a frame.
- Slots can have *specified attributes*. For example, we might specify that instrument can have multiple values, that each value can only be an instance of Instrument, that each value has a slot called owned\_by and so on.
- Slots may contain arbitrary pieces of program. This is known as *procedural attachment*. The fragment might be executed to return the slot's value, or update the values in other slots *etc*.

## Forward chaining

The first of two basic kinds of interpreter begins with established facts and then applies rules to them.

This is a *data-driven* process. It is appropriate if we know the *initial facts* but not the required conclusion.

Example: XCON-used for configuring VAX computers.

In addition:

- We maintain a *working memory*, typically of what has been inferred so far.
- Rules are often *condition-action rules*, where the right-hand side specifies an action such as adding or removing something from working memory, printing a message *etc*.
- In some cases actions might be entire program fragments.

## Forward chaining Example The basic algorithm is: Condition-action rules dry mouth -> ADD thirsty 1. Find all the rules that can fire, based on the current working thirsty -> ADD get\_drink get drink AND no work -> ADD go bar memory. working -> ADD no work no work -> DELETE working 2. Select a rule to fire. This requires a *conflict resolution strategy*. Interpreter Working memory 3. Carry out the action specified, possibly updating the working memory. dry mouth working Repeat this process until either no rules can be used or a halt appears in the working memory. Conflict resolution Example Progress is as follows: Clearly in any more realistic system we expect to have to deal with a scenario where two or more rules can be fired at any one time: 1. The rule $dry_mouth \Longrightarrow ADD$ thirsty • Which rule we choose can clearly affect the outcome. fires adding thirsty to working memory. • We might also want to attempt to avoid inferring an abundance 2. The rule of useless information. $thirsty \Longrightarrow ADD get_drink$ fires adding get\_drink to working memory. We therefore need a means of *resolving such conflicts*. 3. The rule working $\Longrightarrow$ ADD no\_work fires adding no\_work to working memory. 4. The rule $get\_drink AND no\_work \Longrightarrow ADD go\_bar$ fires, and we establish that it's time to go to the bar.

#### Conflict resolution

Common conflict resolution strategies are:

- Prefer rules involving more recently added facts.
- Prefer rules that are *more specific*. For example

 $\texttt{patient\_coughing} \Longrightarrow \texttt{ADD} \texttt{lung\_problem}$ 

is more general than

 $\texttt{patient\_coughing AND patient\_smoker} \Longrightarrow \texttt{ADD lung\_cancer}.$ 

This allows us to define exceptions to general rules.

- Allow the designer of the rules to specify priorities.
- Fire all rules *simultaneously*—this essentially involves following all chains of inference at once.

#### Reason maintenance

Some systems will allow information to be removed from the working memory if it is no longer *justified*.

For example, we might find that

patient\_coughing

and

patient\_smoker

are in working memory, and hence fire

 $\texttt{patient\_coughing} \ \texttt{AND} \ \texttt{patient\_smoker} \Longrightarrow \texttt{ADD} \ \texttt{lung\_cancer}$ 

but later infer something that causes  $\verb"patient_coughing"$  to be withdrawn from working memory.

The justification for lung\_cancer has been removed, and so it should perhaps be removed also.

## Pattern matching

In general rules may be expressed in a slightly more flexible form involving *variables* which can work in conjunction with *pattern matching*.

For example the rule

```
\operatorname{coughs}(X) \operatorname{AND} \operatorname{smoker}(X) \Longrightarrow \operatorname{ADD} \operatorname{lung\_cancer}(X)
```

contains the variable X.

If the working memory contains  $\mbox{coughs}(\mbox{neddy})$  and  $\mbox{smoker}(\mbox{neddy})$  then

X = neddy

provides a match and

lung\_cancer(neddy)

is added to the working memory.

## Backward chaining

The second basic kind of interpreter begins with a *goal* and finds a rule that would achieve it.

It then works *backwards*, trying to achieve the resulting earlier goals in the succession of inferences.

$$\label{eq:main_example: MYCIN} \begin{split} & \text{Example: MYCIN} \text{---medical diagnosis with a small number of conditions.} \end{split}$$

This is a *goal-driven* process. If you want to *test a hypothesis* or you have some idea of a likely conclusion it can be more efficient than forward chaining.
