## Contents

**Learning Guide**

**Exercises and Tripos Questions**

**Introduction: algorithmically undecidable problems**

- Decision problems. The informal notion of algorithm, or effective procedure. Examples of algorithmically undecidable problems.
  - [1 lecture]

**Register machines**

- Definition and examples; graphical notation. Register machine computable functions. Doing arithmetic with register machines.
  - [1 lecture]

**Coding programs as numbers**

- Natural number encoding of pairs and lists. Coding register machine programs as numbers.
  - [1 lecture]

**Universal register machine**

- Specification and implementation of a universal register machine.
  - [1 lectures]

**The halting problem**

- Statement and proof of undecidability. Example of an uncomputable partial function. Decidable sets of numbers; examples of undecidable sets of numbers.
  - [1 lecture]

**Turing machines**

  - [2 lectures]

**Primitive and partial recursive functions**

- Definition and examples. Existence of a recursive, but not primitive recursive function. A partial function is partial recursive if and only if it is computable.
  - [2 lectures]

**Lambda calculus**

- Alpha and beta conversion. Normalization. Encoding data. Writing recursive functions in the \( \lambda \)-calculus. The relationship between computable functions and \( \lambda \)-definable functions.
  - [3 lectures]
Learning Guide

These notes are designed to accompany 12 lectures on computation theory for Part IB of the Computer Science Tripos. The aim of this course is to introduce several apparently different formalisations of the informal notion of algorithm; to show that they are equivalent; and to use them to demonstrate that there are uncomputable functions and algorithmically undecidable problems. At the end of the course you should:

- be familiar with the register machine, Turing machine and $\lambda$-calculus models of computability;
- understand the notion of coding programs as data, and of a universal machine;
- be able to use diagonalisation to prove the undecidability of the Halting Problem;
- understand the mathematical notion of partial recursive function and its relationship to computability.

The prerequisites for taking this course are the Part IA courses Discrete Mathematics and Regular Languages and Finite Automata.

This Computation Theory course contains some material that everyone who calls themselves a computer scientist should know. It is also a prerequisite for the Part IB course on Complexity Theory.

Recommended books

Exercises and Tripos Questions

A course on Computation Theory has been offered for many years. Since 2009 the course has incorporated some material from a Part IB course on Foundations of Functional Programming that is no longer offered. A guide to which Tripos questions from the last five years are relevant to the current course can be found on the course web page (follow links from www.cl.cam.ac.uk/teaching/). Here are suggestions for which of the older ones to try, together with some other exercises.

1. Exercises in register machine programming:
   (a) Produce register machine programs for the functions mentioned on slides 36 and 37.
   (b) Try Tripos question 1999.3.9.

2. Undecidability of the halting problem:
   (a) Try Tripos question 1995.3.9.
   (b) Try Tripos question 2000.3.9.
   (c) Learn by heart the poem about the undecidability of the halting problem to be found at the course web page and recite it to your non-compsci friends.

3. Let \( \phi_e \) denote the unary partial function from numbers to numbers (i.e. an element of \( \mathbb{N} \to \mathbb{N} \)—cf. slide 30) computed by the register machine with code \( e \) (cf. slide 63). Show that for any given register machine computable unary partial function \( f \), there are infinitely many numbers \( e \) such that \( \phi_e = f \). (Equality of partial functions means that they are equal as sets of ordered pairs; which is equivalent to saying that for all numbers \( x \), \( \phi_e(x) \) is defined if and only if \( f(x) \) is, and in that case they are equal numbers.)

4. Suppose \( S_1 \) and \( S_2 \) are subsets of the set \( \mathbb{N} = \{0,1,2,3,\ldots\} \) of natural numbers. Suppose \( f \in \mathbb{N} \to \mathbb{N} \) is register machine computable and satisfies: for all \( x \) in \( \mathbb{N} \), \( x \) is an element of \( S_1 \) if and only if \( f(x) \) is an element of \( S_2 \). Show that \( S_1 \) is register machine decidable (cf. slide 66) if \( S_2 \) is.

5. Show that the set of codes \( \langle e, e' \rangle \) of pairs of numbers \( e \) and \( e' \) satisfying \( \phi_e = \phi_{e'} \) is undecidable.

6. For the example Turing machine given on slide 75, give the register machine program implementing

\[
(S, T, D) := \delta(S, T)
\]

as described on slide 83. [Tedious!—maybe just do a bit.]

7. Try Tripos question 2001.3.9. [This is the Turing machine version of 2000.3.9.]

8. Try Tripos question 1996.3.9.

9. Show that the following functions are all primitive recursive.
   (a) Exponentiation, \( \exp(x, y) \triangleq x^y \).
(b) Truncated subtraction, minus\((x, y) \triangleq \begin{cases} x - y & \text{if } x \geq y \\ 0 & \text{if } x < y \end{cases}\)

(c) Conditional branch on zero, ifzero\((x, y, z) \triangleq \begin{cases} y & \text{if } x = 0 \\ z & \text{if } x > 0 \end{cases}\)

(d) Bounded summation: if \(f \in \mathbb{N}^{n+1} \rightarrow \mathbb{N}\) is primitive recursive, then so is \(g \in \mathbb{N}^{n+1} \rightarrow \mathbb{N}\) where
\[
g(\vec{x}, x) \triangleq \begin{cases} 0 & \text{if } x = 0 \\ f(\vec{x}, 0) & \text{if } x = 1 \\ f(\vec{x}, 0) + \cdots + f(\vec{x}, x - 1) & \text{if } x > 1. \end{cases}
\]

10. Recall the definition of Ackermann’s function \(ack\) from slide 122. Sketch how to build a register machine \(M\) that computes \(ack(x_1, x_2)\) in \(R_0\) when started with \(x_1\) in \(R_1\) and \(x_2\) in \(R_2\) and all other registers zero. [Hint: here’s one way; the next question steers you another way to the computability of \(ack\). Call a finite list \(L = [(x_1, y_1, z_1), (x_2, y_2, z_2), \ldots]\) of triples of numbers suitable if it satisfies
   (i) if \((0, y, z) \in L\), then \(z = y + 1\)
   (ii) if \((x + 1, 0, z) \in L\), then \((x, 1, z) \in L\)
   (iii) if \((x + 1, y + 1, z) \in L\), then there is some \(u\) with \((x + 1, y, u) \in L\) and \((x, u, z) \in L\).

   The idea is that if \((x, y, z) \in L\) and \(L\) is suitable then \(z = ack(x, y)\) and \(L\) contains all the triples \((x', y', ack(x', y'))\) needed to calculate \(ack(x, y)\). Show how to code lists of triples of numbers as numbers in such a way that we can (in principle, no need to do it explicitly!) build a register machine that recognizes whether or not a number is the code for a suitable list of triples. Show how to use that machine to build a machine computing \(ack(x, y)\) by searching for the code of a suitable list containing a triple with \(x\) and \(y\) in it’s first two components.]

11. If you are not already fed up with Ackermann’s function, try Tripos question 2001.4.8.

12. If you are still not fed up with Ackermann’s function \(ack \in \mathbb{N}^2 \rightarrow \mathbb{N}\), show that the \(\lambda\)-term \(ack \triangleq \lambda x. (\lambda y. y f (f \lambda 1)) \text{Succ}\) represents \(ack\) (where \(\text{Succ}\) is as on slide 152).

13. Let \(I\) be the \(\lambda\)-term \(\lambda x. x\). Show that \(\nu I =_\beta \lambda\) holds for every Church numeral \(\nu\). Now consider
\[
B \triangleq \lambda f g x. g x \lambda (f (g x))
\]

Assuming the fact about normal order reduction mentioned on slide 145, show that if partial functions \(f, g \in \mathbb{N} \rightarrow \mathbb{N}\) are represented by closed \(\lambda\)-terms \(F\) and \(G\) respectively, then their composition \((f \circ g)(x) \equiv f(g(x))\) is represented by \(B F G\). Now try Tripos question 2005.5.12.
Algorithmically undecidable problems

Computers cannot solve all mathematical problems, even if they are given unlimited time and working space. Three famous examples of computationally unsolvable problems are sketched in this lecture.

- Hilbert’s *Entscheidungsproblem*
- The Halting Problem
- Hilbert’s 10th Problem.
Hilbert’s Entscheidungsproblem

Is there an algorithm which when fed any statement in the formal language of first-order arithmetic, determines in a finite number of steps whether or not the statement is provable from Peano’s axioms for arithmetic, using the usual rules of first-order logic?

Such an algorithm would be useful! For example, by running it on

$$\forall k > 1 \exists p, q \ (2k = p + q \land \text{prime}(p) \land \text{prime}(q))$$

(where $\text{prime}(p)$ is a suitable arithmetic statement that $p$ is a prime number) we could solve Goldbach’s Conjecture (“every strictly positive even number is the sum of two primes”), a famous open problem in number theory.

Posed by Hilbert at the 1928 International Congress of Mathematicians. The problem was actually stated in a more ambitious form, with a more powerful formal system in place of first-order logic.

In 1928, Hilbert believed that such an algorithm could be found. A few years later he was proved wrong by the work of Church and Turing in 1935/36, as we will see.
Decision problems

Entscheidungsproblem means “decision problem”. Given

- a set $S$ whose elements are finite data structures of some kind
  (e.g. formulas of first-order arithmetic)
- a property $P$ of elements of $S$
  (e.g. property of a formula that it has a proof)

the associated decision problem is:

find an algorithm which terminates with result 0 or 1 when fed an element $s \in S$ and yields result 1 when fed $s$ if and only if $s$ has property $P$.

Algorithms, informally

No precise definition of “algorithm” at the time Hilbert posed the Entscheidungsproblem, just examples, such as:

- Procedure for multiplying numbers in decimal place notation.
- Procedure for extracting square roots to any desired accuracy.
- Euclid’s algorithm for finding highest common factors.
Algorithms, informally

No precise definition of “algorithm” at the time Hilbert posed the *Entscheidungsproblem*, just examples.

Common features of the examples:

- finite description of the procedure in terms of elementary operations
- deterministic (next step uniquely determined if there is one)
- procedure may not terminate on some input data, but we can recognize when it does terminate and what the result is.

In 1935/36 Turing in Cambridge and Church in Princeton independently gave negative solutions to Hilbert’s *Entscheidungsproblem*.

- First step: give a precise, mathematical definition of “algorithm”.
  (Turing: Turing Machines; Church: lambda-calculus.)
- Then one can regard algorithms as data on which algorithms can act and reduce the problem to...
The Halting Problem

is the decision problem with

- set $S$ consists of all pairs $(A, D)$, where $A$ is an algorithm and $D$ is a datum on which it is designed to operate;
- property $P$ holds for $(A, D)$ if algorithm $A$ when applied to datum $D$ eventually produces a result (that is, eventually halts—we write $A(D) \downarrow$ to indicate this).

Turing and Church’s work shows that the Halting Problem is undecidable, that is, there is no algorithm $H$ such that for all $(A, D) \in S$

$$H(A, D) = \begin{cases} 
1 & \text{if } A(D) \downarrow \\
0 & \text{otherwise.}
\end{cases}$$

There’s no $H$ such that $H(A, D) = \begin{cases} 
1 & \text{if } A(D) \downarrow \\
0 & \text{otherwise.}
\end{cases}$ for all $(A, D)$.

Informal proof, by contradiction. If there were such an $H$, let $C$ be the algorithm:

“input $A$; compute $H(A, A)$; if $H(A, A) = 0$ then return 1, else loop forever.”

So $\forall A \ (C(A) \downarrow \leftrightarrow H(A, A) = 0)$ (since $H$ is total)
and $\forall A \ (H(A, A) = 0 \leftrightarrow \neg A(A) \downarrow)$ (definition of $H$).
So $\forall A \ (C(A) \downarrow \leftrightarrow \neg A(A) \downarrow)$.
Taking $A$ to be $C$, we get $C(C) \downarrow \leftrightarrow \neg C(C) \downarrow$, contradiction!
From HP to Entscheidungsproblem

Final step in Turing/Church proof of undecidability of the Entscheidungsproblem: they constructed an algorithm encoding instances \((A, D)\) of the Halting Problem as arithmetic statements \(\Phi_{A,D}\) with the property

\[\Phi_{A,D} \text{ is provable } \iff A(D)\downarrow\]

Thus any algorithm deciding provability of arithmetic statements could be used to decide the Halting Problem—so no such exists.

Hilbert’s Entscheidungsproblem

Is there an algorithm which when fed any statement in the formal language of first-order arithmetic, determines in a finite number of steps whether or not the statement is provable from Peano’s axioms for arithmetic, using the usual rules of first-order logic?

With hindsight, a positive solution to the Entscheidungsproblem would be too good to be true. However, the algorithmic unsolvability of some decision problems is much more surprising. A famous example of this is...
Hilbert’s 10th Problem

Give an algorithm which, when started with any Diophantine equation, determines in a finite number of operations whether or not there are natural numbers satisfying the equation.

One of a number of important open problems listed by Hilbert at the International Congress of Mathematicians in 1900.

Diophantine equations

\[ p(x_1, \ldots, x_n) = q(x_1, \ldots, x_n) \]

where \( p \) and \( q \) are polynomials in unknowns \( x_1, \ldots, x_n \) with coefficients from \( \mathbb{N} = \{0, 1, 2, \ldots\} \).

Named after Diophantus of Alexandria (c. 250AD).

Example: “find three whole numbers \( x_1, x_2 \) and \( x_3 \) such that the product of any two added to the third is a square” [Diophantus’ Arithmetica, Book III, Problem 7].

In modern notation: find \( x_1, x_2, x_2 \in \mathbb{N} \) for which there exists \( x, y, z \in \mathbb{N} \) with

\[ x_1^2x_2^2 + x_2^2x_3^2 + x_3^2x_1^2 + \cdots = x^2x_1x_2 + y^2x_2x_3 + z^2x_3x_1 + \cdots \]

[One solution: \( (x_1, x_2, x_3) = (1, 4, 12) \), with \( (x, y, z) = (4, 7, 4) \).]
Hilbert’s 10th Problem

Give an algorithm which, when started with any Diophantine equation, determines in a finite number of operations whether or not there are natural numbers satisfying the equation.

- Posed in 1900, but only solved in 1990: Y Matijasevič, J Robinson, M Davis and H Putnam show it undecidable by reduction to the Halting Problem.

- Original proof used Turing machines. Later, simpler proof [JP Jones & Y Matijasevič, J. Symb. Logic 49(1984)] used Minsky and Lambek’s register machines—we will use them in this course to begin with and return to Turing and Church’s formulations of the notion of “algorithm” later.
Register Machines

Algorithms, informally

No precise definition of “algorithm” at the time Hilbert posed the *Entscheidungsproblem*, just examples.

Common features of the examples:

- finite description of the procedure in terms of elementary operations
- deterministic (next step uniquely determined if there is one)
- procedure may not terminate on some input data, but we can recognize when it does terminate and what the result is.
Register Machines, informally

They operate on natural numbers \( \mathbb{N} = \{0, 1, 2, \ldots\} \) stored in (idealized) registers using the following “elementary operations”:

- add 1 to the contents of a register
- test whether the contents of a register is 0
- subtract 1 from the contents of a register if it is non-zero
- jumps (“goto”)
- conditionals (“if_then_else_”)

**Definition.** A register machine is specified by:

- finitely many registers \( R_0, R_1, \ldots, R_n \) (each capable of storing a natural number);
- a program consisting of a finite list of instructions of the form \( label : body \), where for \( i = 0, 1, 2, \ldots \), the \((i + 1)^{th}\) instruction has label \( L_i \).

Instruction body takes one of three forms:

<table>
<thead>
<tr>
<th>( R^+ \rightarrow L' )</th>
<th>add 1 to contents of register ( R ) and jump to instruction labelled ( L' )</th>
</tr>
</thead>
<tbody>
<tr>
<td>( R^- \rightarrow L', L'' )</td>
<td>if contents of ( R ) is &gt; 0, then subtract 1 from it and jump to ( L' ), else jump to ( L'' )</td>
</tr>
<tr>
<td>HALT</td>
<td>stop executing instructions</td>
</tr>
</tbody>
</table>
Example

 registers:
R₀ R₁ R₂

 program:
L₀ : R₁ → L₁, L₂
L₁ : R₀ → L₀
L₂ : R₂ → L₃, L₄
L₃ : R₀ → L₂
L₄ : HALT

element computation:

<table>
<thead>
<tr>
<th>Lᵢ</th>
<th>R₀</th>
<th>R₁</th>
<th>R₂</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>1</td>
<td>2</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
<td>0</td>
<td>2</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
<td>0</td>
<td>2</td>
</tr>
<tr>
<td>2</td>
<td>1</td>
<td>0</td>
<td>2</td>
</tr>
<tr>
<td>3</td>
<td>1</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>2</td>
<td>2</td>
<td>0</td>
<td>1</td>
</tr>
<tr>

<tr>
<td>4</td>
<td>3</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>

Register machine computation

Register machine configuration:

\[ c = (\ell, r₀, \ldots, rₙ) \]

where \( \ell \) = current label and \( rᵢ \) = current contents of \( Rᵢ \).

**Notation:** “\( Rᵢ = x \) [in configuration \( c \)]” means \( c = (\ell, r₀, \ldots, rₙ) \) with \( rᵢ = x \).

Initial configurations:

\[ c₀ = (0, r₀, \ldots, rₙ) \]

where \( rᵢ \) = initial contents of register \( Rᵢ \).
Register machine computation

A computation of a RM is a (finite or infinite) sequence of configurations

\[ c_0, c_1, c_2, \ldots \]

where

- \( c_0 = (0, r_0, \ldots, r_n) \) is an initial configuration
- each \( c = (\ell, r_0, \ldots, r_n) \) in the sequence determines the next configuration in the sequence (if any) by carrying out the program instruction labelled \( L_\ell \) with registers containing \( r_0, \ldots, r_n \).

Halting

For a finite computation \( c_0, c_1, \ldots, c_m \), the last configuration \( c_m = (\ell, r, \ldots) \) is a halting configuration, i.e. instruction labelled \( L_\ell \) is

either HALT (a “proper halt”)

or \( R^+ \rightarrow L \), or \( R^- \rightarrow L, L' \) with \( R > 0 \), or \( R^- \rightarrow L', L \) with \( R = 0 \)

and there is no instruction labelled \( L \) in the program (an “erroneous halt”)

E.g. \( L_0 : R_0^+ \rightarrow L_2 \) halts erroneously.

E.g. \( L_1 : \text{HALT} \)
Halting

For a finite computation \( c_0, c_1, \ldots, c_m \), the last configuration \( c_m = (l, r, \ldots) \) is a halting configuration.

Note that computations may never halt. For example,

\[
\begin{align*}
L_0 & : R_0^+ \rightarrow L_0 \\
L_1 & : \text{HALT}
\end{align*}
\]

only has infinite computation sequences

\[(0, r), (0, r + 1), (0, r + 2), \ldots\]

Graphical representation

- one node in the graph for each instruction
- arcs represent jumps between instructions
- lose sequential ordering of instructions—so need to indicate initial instruction with START.

<table>
<thead>
<tr>
<th>instruction</th>
<th>representation</th>
</tr>
</thead>
<tbody>
<tr>
<td>( R^+ \rightarrow L )</td>
<td>( R^+ \rightarrow [L] )</td>
</tr>
<tr>
<td>( R^- \rightarrow L, L' )</td>
<td>( R^- \rightarrow [L'], [L] )</td>
</tr>
<tr>
<td>HALT</td>
<td>HALT</td>
</tr>
<tr>
<td>( L_0 )</td>
<td>START \rightarrow [L_0]</td>
</tr>
</tbody>
</table>
Example

registers:
R₀ R₁ R₂

program:
L₀ : R₁⁻ → L₁, L₂
L₁ : R₀⁺ → L₀
L₂ : R₂⁻ → L₃, L₄
L₃ : R₀⁺ → L₂
L₄ : HALT

graphical representation:

START

R₁⁻ ↔ R₀⁺

R₂⁻ ↔ R₀⁺

HALT

Claim: starting from initial configuration (0, 0, x, y), this machine's computation halts with configuration (4, x + y, 0, 0).

Partial functions

Register machine computation is deterministic: in any non-halting configuration, the next configuration is uniquely determined by the program.
So the relation between initial and final register contents defined by a register machine program is a partial function...

Definition. A partial function from a set \( X \) to a set \( Y \) is specified by any subset \( f \subseteq X \times Y \) satisfying

\[(x, y) \in f \land (x, y') \in f \rightarrow y = y'\]

for all \( x \in X \) and \( y, y' \in Y \).
Partial functions

Definition. A partial function from a set $X$ to a set $Y$ is specified by any subset $f \subseteq X \times Y$ satisfying

$$(x, y) \in f \land (x, y') \in f \rightarrow y = y'$$

for all $x \in X$ and $y, y' \in Y$.

Computation Theory, L 2

Partial functions

Notation:

- “$f(x) = y$” means $(x, y) \in f$
- “$f(x) \downarrow$” means $\exists y \in Y (f(x) = y)$
- “$f(x) \uparrow$” means $\neg \exists y \in Y (f(x) = y)$

$X \rightarrow Y = \text{set of all partial functions from } X \text{ to } Y$

$X \rightarrow Y = \text{set of all (total) functions from } X \text{ to } Y$

Definition. A partial function from a set $X$ to a set $Y$ is total if it satisfies

$$f(x) \downarrow$$

for all $x \in X$. 
Computable functions

**Definition.** \( f \in \mathbb{N}^n \rightarrow \mathbb{N} \) is (register machine) computable if there is a register machine \( M \) with at least \( n + 1 \) registers \( R_0, R_1, \ldots, R_n \) (and maybe more) such that for all \((x_1, \ldots, x_n) \in \mathbb{N}^n\) and all \( y \in \mathbb{N}\),

the computation of \( M \) starting with \( R_0 = 0, R_1 = x_1, \ldots, R_n = x_n \) and all other registers set to 0, halts with \( R_0 = y \)

if and only if \( f(x_1, \ldots, x_n) = y \).

Note the [somewhat arbitrary] I/O convention: in the initial configuration registers \( R_1, \ldots, R_n \) store the function’s arguments (with all others zeroed); and in the halting configuration register \( R_0 \) stores its value (if any).

---

Example

<table>
<thead>
<tr>
<th>registers:</th>
<th>graphical representation:</th>
</tr>
</thead>
<tbody>
<tr>
<td>( R_0, R_1, R_2 )</td>
<td>START</td>
</tr>
<tr>
<td>program:</td>
<td>( R_1^- \leftrightarrow R_0^+ )</td>
</tr>
<tr>
<td>( L_0 : R_1^- \rightarrow L_1, L_2 )</td>
<td>( R_2^- \leftrightarrow R_0^+ )</td>
</tr>
<tr>
<td>( L_1 : R_0^+ \rightarrow L_0 )</td>
<td></td>
</tr>
<tr>
<td>( L_2 : R_2^- \rightarrow L_3, L_4 )</td>
<td>HALT</td>
</tr>
<tr>
<td>( L_3 : R_0^+ \rightarrow L_2 )</td>
<td></td>
</tr>
<tr>
<td>( L_4 : \text{HALT} )</td>
<td></td>
</tr>
</tbody>
</table>

**Claim:** starting from initial configuration \((0, 0, x, y)\), this machine’s computation halts with configuration \((4, x + y, 0, 0)\). So \( f(x, y) \triangleq x + y \) is computable.
Computable functions

Recall:

**Definition.** \( f \in \mathbb{N}^n \rightarrow \mathbb{N} \) is (register machine) computable if there is a register machine \( M \) with at least \( n + 1 \) registers \( R_0, R_1, \ldots, R_n \) (and maybe more) such that for all \( (x_1, \ldots, x_n) \in \mathbb{N}^n \) and all \( y \in \mathbb{N} \), the computation of \( M \) starting with \( R_0 = 0 \), \( R_1 = x_1, \ldots, R_n = x_n \) and all other registers set to 0, halts with \( R_0 = y \) if and only if \( f(x_1, \ldots, x_n) = y \).

Multiplication \( f(x, y) \triangleq xy \) is computable
Multiplication $f(x, y) \triangleq xy$ is computable

If the machine is started with $(R_0, R_1, R_2, R_3) = (0, x, y, 0)$, it halts with $(R_0, R_1, R_2, R_3) = (xy, 0, y, 0)$.

Further examples

The following arithmetic functions are all computable. (Proof—left as an exercise!)

projection: $p(x, y) \triangleq x$

constant: $c(x) \triangleq n$

truncated subtraction: $x \cdot y \triangleq \begin{cases} x - y & \text{if } y \leq x \\ 0 & \text{if } y > x \end{cases}$
Further examples

The following arithmetic functions are all computable. (Proof—left as an exercise!)

integer division:
\[ x \div y \triangleq \begin{cases} 
\text{integer part of } x/y & \text{if } y > 0 \\
0 & \text{if } y = 0 
\end{cases} \]

integer remainder: \[ x \mod y \triangleq x \div y (x \div y) \]

exponentiation base 2: \[ e(x) \triangleq 2^x \]

logarithm base 2:
\[ \log_2(x) \triangleq \begin{cases} 
\text{greatest } y \text{ such that } 2^y \leq x & \text{if } x > 0 \\
0 & \text{if } x = 0 
\end{cases} \]
Turing/Church solution of the Entscheidungsproblem uses the idea that (formal descriptions of) algorithms can be the data on which algorithms act.

To realize this idea with Register Machines we have to be able to code RM programs as numbers. (In general, such codings are often called Gödel numberings.)

To do that, first we have to code pairs of numbers and lists of numbers as numbers. There are many ways to do that. We fix upon one...
Numerical coding of pairs

For \( x, y \in \mathbb{N} \), define \[
\langle \langle x, y \rangle \rangle \triangleq 2^x(2y + 1) \]
\[
\langle x, y \rangle \triangleq 2^x(2y + 1) - 1
\]

So
\[
0b\langle \langle x, y \rangle \rangle = \begin{array}{c}
0b y \\
0b y + 1
\end{array} 0 \cdots 0
\]
\[
0b\langle x, y \rangle = \begin{array}{c}
0b y \\
0b y + 1
\end{array} 0 \cdots 1
\]

(Notation: \( 0bx \triangleq x \text{ in binary} \).)

E.g. \( 27 = 0b11011 = \langle \langle 0, 13 \rangle \rangle = \langle 2, 3 \rangle \)

\langle \langle -,- \rangle \rangle \text{ gives a bijection (one-one correspondence) between } \mathbb{N} \times \mathbb{N} \text{ and } \mathbb{N}.

\langle -,- \rangle \text{ gives a bijection between } \mathbb{N} \times \mathbb{N} \text{ and } \{ n \in \mathbb{N} \mid n \neq 0 \}.
Numerical coding of lists

\( \text{list } \mathbb{N} \triangleq \) set of all finite lists of natural numbers, using ML notation for lists:

- empty list: \([\,]\)
- list-cons: \(x :: \ell \in \text{list } \mathbb{N}\) (given \(x \in \mathbb{N}\) and \(\ell \in \text{list } \mathbb{N}\))
- \([x_1, x_2, \ldots, x_n] \triangleq x_1 :: (x_2 :: (\cdots x_n :: [] \cdots))\)

For \(\ell \in \text{list } \mathbb{N}\), define \(\text{⌜ } \ell \text{⌝} \in \mathbb{N}\) by induction on the length of the list \(\ell\):

\[
\begin{cases}
\text{⌜ } [] \text{⌝} \triangleq 0 \\
\text{⌜ } x :: \ell \text{⌝} \triangleq 2^x (2 \cdot \text{⌜ } \ell \text{⌝} + 1)
\end{cases}
\]

Thus \(\text{⌜ } [x_1, x_2, \ldots, x_n] \text{⌝} = \langle x_1, \langle x_2, \cdots \langle x_n, 0 \rangle \cdots \rangle \rangle\)
Numerical coding of lists

\[ \text{list} \mathbb{N} \triangleq \text{set of all finite lists of natural numbers, using ML notation for lists.} \]

For \( \ell \in \text{list} \mathbb{N} \), define \( \llbracket \ell \rrbracket \in \mathbb{N} \) by induction on the length of the list \( \ell \):

\[
\begin{align*}
\llbracket [] \rrbracket & \triangleq 0 \\
\llbracket x :: \ell \rrbracket & \triangleq \langle \langle x, \llbracket \ell \rrbracket \rangle \rangle = 2^x (2 \cdot \llbracket \ell \rrbracket + 1)
\end{align*}
\]

For example:

\[
\begin{align*}
\llbracket [3] \rrbracket & = \llbracket 3 :: [] \rrbracket = \langle \langle 3, 0 \rangle \rangle = 2^3 (2 \cdot 0 + 1) = 8 = 0b1000 \\
\llbracket [1, 3] \rrbracket & = \llbracket [1, \llbracket 3 \rrbracket] \rrbracket = \langle \langle 1, 3 \rangle \rangle = 34 = 0b100010 \\
\llbracket [2, 1, 3] \rrbracket & = \llbracket [2, \llbracket 1, 3 \rrbracket] \rrbracket = \langle \langle 2, 34 \rangle \rangle = 276 = 0b100010100
\end{align*}
\]

Hence \( \ell \mapsto \llbracket \ell \rrbracket \) gives a bijection from \( \text{list} \mathbb{N} \) to \( \mathbb{N} \).

Computation Theory, L 3 44/171

Numerical coding of lists

\[ \text{list} \mathbb{N} \triangleq \text{set of all finite lists of natural numbers, using ML notation for lists.} \]

For \( \ell \in \text{list} \mathbb{N} \), define \( \llbracket \ell \rrbracket \in \mathbb{N} \) by induction on the length of the list \( \ell \):

\[
\begin{align*}
\llbracket [] \rrbracket & \triangleq 0 \\
\llbracket x :: \ell \rrbracket & \triangleq \langle \langle x, \llbracket \ell \rrbracket \rangle \rangle = 2^x (2 \cdot \llbracket \ell \rrbracket + 1)
\end{align*}
\]

For example:

\[
\begin{align*}
\llbracket [3] \rrbracket & = \llbracket 3 :: [] \rrbracket = \langle \langle 3, 0 \rangle \rangle = 2^3 (2 \cdot 0 + 1) = 8 = 0b1000 \\
\llbracket [1, 3] \rrbracket & = \llbracket [1, \llbracket 3 \rrbracket] \rrbracket = \langle \langle 1, 3 \rangle \rangle = 34 = 0b100010 \\
\llbracket [2, 1, 3] \rrbracket & = \llbracket [2, \llbracket 1, 3 \rrbracket] \rrbracket = \langle \langle 2, 34 \rangle \rangle = 276 = 0b100010100
\end{align*}
\]

Computation Theory, L 3 45/171
Numerical coding of programs

If $P$ is the RM program

\[
\begin{align*}
L_0 &: body_0 \\
L_1 &: body_1 \\
& \quad \vdots \\
L_n &: body_n
\end{align*}
\]

then its numerical code is

\[
⌜P⌝ ≜ ⌜[⌜body_0⌝, \ldots, ⌜body_n⌝]⌝
\]

where the numerical code $⌜body⌝$ of an instruction body is defined by:

\[
\begin{align*}
⌜R_i^+ \rightarrow L_j⌝ & ≜ ⟨⟨2i, j⟩⟩ \\
⌜R_i^- \rightarrow L_j, L_k⌝ & ≜ ⟨⟨2i + 1, ⟨j, k⟩⟩⟩ \\
⌜HALT⌝ & ≜ 0
\end{align*}
\]

Any $x \in \mathbb{N}$ decodes to a unique instruction $body(x)$:

if $x = 0$ then $body(x)$ is $HALT$,
else ($x > 0$ and) let $x = ⟨⟨y, z⟩⟩$ in
   if $y = 2i$ is even, then $body(x)$ is $R_i^+ \rightarrow L_z$,
   else $y = 2i + 1$ is odd, let $z = ⟨j, k⟩$ in $body(x)$ is $R_i^- \rightarrow L_j, L_k$

So any $e \in \mathbb{N}$ decodes to a unique program $prog(e)$, called the register machine program with index $e$:

\[
prog(e) ≜ \begin{align*}
L_0 &: body(x_0) \\
& \quad \vdots \\
L_n &: body(x_n)
\end{align*}
\]

where $e = ⌜[x_0, \ldots, x_n]⌝$
Example of $\text{prog}(e)$

- $786432 = 2^{19} + 2^{18} = 0b110\ldots0 = \lbrack 18, 0 \rbrack^\uparrow$
  
  - $18 = 0b10010 = \langle 1, 4 \rangle = \langle 1, \langle 0, 2 \rangle \rangle = \langle R_0^-, L_0, L_2 \rangle$
  
- $0 = \langle \text{HALT} \rangle$

So $\text{prog}(786432) = \begin{array}{c}
L_0 : R_0^- \rightarrow L_0, L_2 \\
L_1 : \text{HALT}
\end{array}$

N.B. In case $e = 0$ we have $0 = \lbrack \rbrack^\uparrow$, so $\text{prog}(0)$ is the program with an empty list of instructions, which by convention we regard as a RM that does nothing (i.e. that halts immediately).
Universal Register Machine, $U$

High-level specification

Universal RM $U$ carries out the following computation, starting with $R_0 = 0$, $R_1 = e$ (code of a program), $R_2 = a$ (code of a list of arguments) and all other registers zeroed:

- decode $e$ as a RM program $P$
- decode $a$ as a list of register values $a_1, \ldots, a_n$
- carry out the computation of the RM program $P$ starting with $R_0 = 0, R_1 = a_1, \ldots, R_n = a_n$ (and any other registers occurring in $P$ set to 0).
Mnemonics for the registers of $U$ and the role they play in its program:

- $R_1 \equiv P$ code of the RM to be simulated
- $R_2 \equiv A$ code of current register contents of simulated RM
- $R_3 \equiv PC$ program counter—number of the current instruction (counting from 0)
- $R_4 \equiv N$ code of the current instruction body
- $R_5 \equiv C$ type of the current instruction body
- $R_6 \equiv R$ current value of the register to be incremented or decremented by current instruction (if not HALT)
- $R_7 \equiv S$, $R_8 \equiv T$ and $R_9 \equiv Z$ are auxiliary registers.
- $R_0$ result of the simulated RM computation (if any).

Overall structure of $U$’s program

1. copy $PC$th item of list in $P$ to $N$ (halting if $PC >$ length of list); goto 2

2. if $N = 0$ then halt, else decode $N$ as $\langle y, z \rangle$; $C := y$; $N := z$; goto 3

   {at this point either $C = 2i$ is even and current instruction is $R_i^+ \to L_z$, or $C = 2i + 1$ is odd and current instruction is $R_i^- \to L_j, L_k$ where $z = \langle j, k \rangle$}

3. copy $i$th item of list in $A$ to $R$; goto 4

4. execute current instruction on $R$; update $PC$ to next label; restore register values to $A$; goto 1

To implement this, we need RMs for manipulating (codes of) lists of numbers...
The program $\text{START} \rightarrow [S := R] \rightarrow \text{HALT}$

to copy the contents of $R$ to $S$ can be implemented by

$$\text{START} \rightarrow S^- \rightarrow R^- \rightarrow Z^- \rightarrow \text{HALT}$$

precondition:
$R = x$
$S = y$
$Z = 0$

postcondition:
$R = x$
$S = x$
$Z = 0$

The program $\text{START} \rightarrow \text{push } x \text{ to } L \rightarrow \text{HALT}$

to carry out the assignment $(X,L) ::= (0,X :: L)$ can be implemented by

$$\text{START} \rightarrow Z^+ \rightarrow L^- \rightarrow Z^- \rightarrow X^- \rightarrow \text{HALT}$$

precondition:
$X = x$
$L = \ell$
$Z = 0$

postcondition:
$X = 0$
$L = \langle x, \ell \rangle = 2^x(2\ell + 1)$
$Z = 0$
The program $\text{START} \rightarrow \begin{array}{c} \text{pop } \mathbf{L} \\ \text{to } \mathbf{X} \end{array} \rightarrow \text{HALT} \rightarrow \text{EXIT}$ specified by

"if $\mathbf{L} = 0$ then $(\mathbf{X} ::= 0; \ \text{goto EXIT})$ else let $\mathbf{L} = \langle x, \ell \rangle$ in $(\mathbf{X} ::= x; \ \mathbf{L} ::= \ell; \ \text{goto HALT})"$

can be implemented by

```
START

\[ \begin{array}{c}
\mathbf{X}^- \rightarrow \mathbf{L}^- \rightarrow \mathbf{L}^+ \\
\text{EXIT}
\end{array} \]

\[ \begin{array}{c}
\mathbf{X}^+ \rightarrow \mathbf{L}^- \rightarrow \mathbf{Z}^- \\
\mathbf{Z}^+ \rightarrow \mathbf{L}^+ \\
\text{HALT}
\end{array} \]
```

---

**Overall structure of $\mathbf{U}'s$ program**

1. **copy PCth item of list in $\mathbf{P}$ to $\mathbf{N}$ (halting if PC > length of list); goto 2**

2. **if $\mathbf{N} = 0$ then halt, else decode $\mathbf{N}$ as $\langle y, z \rangle$; $\mathbf{C} ::= y$; $\mathbf{N} ::= z$; goto 3**

   {at this point either $\mathbf{C} = 2i$ is even and current instruction is $R_i^+ \rightarrow L_z$, or $\mathbf{C} = 2i + 1$ is odd and current instruction is $R_i^- \rightarrow L_j, L_k$ where $z = \langle j, k \rangle$}

3. **copy $i$th item of list in $\mathbf{A}$ to $\mathbf{R}$; goto 4**

4. **execute current instruction on $\mathbf{R}$; update PC to next label; restore register values to $\mathbf{A}$; goto 1**
The program for U

START \rightarrow T ::= P \rightarrow pop T to N \rightarrow HALT

pop S to R \rightarrow push R to A \rightarrow pop N to PC

PC ::= N \rightarrow R^+ \rightarrow C^- \rightarrow pop A to R

N^+ \rightarrow C^- \rightarrow push R to S

R^- \rightarrow PC^-
Definition. A register machine $H$ decides the Halting Problem if for all $e, a_1, \ldots, a_n \in \mathbb{N}$, starting $H$ with

$$R_0 = 0 \quad R_1 = e \quad R_2 = \lceil [a_1, \ldots, a_n] \rceil$$

and all other registers zeroed, the computation of $H$ always halts with $R_0$ containing 0 or 1; moreover when the computation halts, $R_0 = 1$ if and only if

the register machine program with index $e$ eventually halts when started with $R_0 = 0, R_1 = a_1, \ldots, R_n = a_n$

and all other registers zeroed.

Theorem. No such register machine $H$ can exist.
Proof of the theorem

Assume we have a RM $H$ that decides the Halting Problem and derive a contradiction, as follows:

- Let $H'$ be obtained from $H$ by replacing $\text{START} \rightarrow$ by $\text{START} \rightarrow [Z := R_1] \rightarrow \text{push } Z \rightarrow \text{to } R_2$ (where $Z$ is a register not mentioned in $H$'s program).

- Let $C$ be obtained from $H'$ by replacing each $\text{HALT}$ ($\&$ each erroneous halt) by $\rightarrow R_0^- \iff R_0^+$. \\

- Let $c \in \mathbb{N}$ be the index of $C$'s program.

$C$ started with $R_1 = c$ eventually halts if & only if $H'$ started with $R_1 = c$ halts with $R_0 = 0$ if & only if $H$ started with $R_1 = c, R_2 = [c]$ halts with $R_0 = 0$ if & only if $\text{prog}(c)$ started with $R_1 = c$ does not halt if & only if $C$ started with $R_1 = c$ does not halt —contradiction!
Computable functions

Recall:

**Definition.** \( f \in \mathbb{N}^n \rightarrow \mathbb{N} \) is (register machine) computable if there is a register machine \( M \) with at least \( n + 1 \) registers \( R_0, R_1, \ldots, R_n \) (and maybe more) such that for all \( (x_1, \ldots, x_n) \in \mathbb{N}^n \) and all \( y \in \mathbb{N} \),

the computation of \( M \) starting with \( R_0 = 0 \),
\( R_1 = x_1, \ldots, R_n = x_n \) and all other registers set to 0, halts with \( R_0 = y \)

if and only if \( f(x_1, \ldots, x_n) = y \).

Note that the same RM \( M \) could be used to compute a unary function \((n = 1)\), or a binary function \((n = 2)\), etc. From now on we will concentrate on the unary case...
An uncomputable function

Let \( f \in \mathbb{N} \to \mathbb{N} \) be the partial function with graph \( \{(x,0) \mid \varphi_x(x) \uparrow\} \).

Thus \( f(x) = \begin{cases} 0 & \varphi_x(x) \uparrow \\ \text{undefined} & \varphi_x(x) \downarrow \end{cases} \)

\( f \) is not computable, because if it were, then \( f = \varphi_e \) for some \( e \in \mathbb{N} \) and hence

- if \( \varphi_e(e) \uparrow \), then \( f(e) = 0 \) (by def. of \( f \)); so \( \varphi_e(e) = 0 \) (by def. of \( e \)), i.e. \( \varphi_e(e) \downarrow \)

- if \( \varphi_e(e) \downarrow \), then \( f(e) \uparrow \) (by def. of \( e \)); so \( \varphi_e(e) \uparrow \) (by def. of \( f \))

—contradiction! So \( f \) cannot be computable.

(Un)decidable sets of numbers

Given a subset \( S \subseteq \mathbb{N} \), its characteristic function \( \chi_S \in \mathbb{N} \to \mathbb{N} \) is given by:

\[ \chi_S(x) \triangleq \begin{cases} 1 & \text{if } x \in S \\ 0 & \text{if } x \notin S \end{cases} \]
(Un)decidable sets of numbers

Definition. $S \subseteq \mathbb{N}$ is called (register machine) decidable if its characteristic function $\chi_S \in \mathbb{N} \rightarrow \mathbb{N}$ is a register machine computable function. Otherwise it is called undecidable.

So $S$ is decidable iff there is a RM $M$ with the property: for all $x \in \mathbb{N}$, $M$ started with $R_0 = 0, R_1 = x$ and all other registers zeroed eventually halts with $R_0$ containing 1 or 0; and $R_0 = 1$ on halting iff $x \in S$.

Basic strategy: to prove $S \subseteq \mathbb{N}$ undecidable, try to show that decidability of $S$ would imply decidability of the Halting Problem.

For example...

Claim: $S_0 \triangleq \{ e \mid \varphi_e(0) \downarrow \} \text{ is undecidable.}$

Proof (sketch): Suppose $M_0$ is a RM computing $\chi_{S_0}$. From $M_0$’s program (using the same techniques as for constructing a universal RM) we can construct a RM $H$ to carry out:

\[
\begin{align*}
\text{let } e & = R_1 \text{ and } \lceil [a_1, \ldots, a_n] \rceil = R_2 \text{ in} \\
R_1 & := \lceil (R_1 := a_1) ; \cdots ; (R_n := a_n) ; \text{prog}(e) \rceil ; \\
R_2 & := 0 ; \\
\text{run } M_0 
\end{align*}
\]

Then by assumption on $M_0, H$ decides the Halting Problem—contradiction. So no such $M_0$ exists, i.e. $\chi_{S_0}$ is uncomputable, i.e. $S_0$ is undecidable.
Claim: \( S_1 \triangleq \{ e \mid \varphi_e \text{ a total function} \} \) is undecidable.

Proof (sketch): Suppose \( M_1 \) is a RM computing \( \chi_{S_1} \). From \( M_1 \)'s program we can construct a RM \( M_0 \) to carry out:

\[
let \ e \ = \ R_1 \ in \ R_1 \ ::= \ \neg R_1 \ ::= \ 0 ; \ prog(e) \downarrow ; \\
run \ M_1 
\]

Then by assumption on \( M_1 \), \( M_0 \) decides membership of \( S_0 \) from previous example (i.e. computes \( \chi_{S_0} \))—contradiction. So no such \( M_1 \) exists, i.e. \( \chi_{S_1} \) is uncomputable, i.e. \( S_1 \) is undecidable.
Algorithms, informally

No precise definition of “algorithm” at the time Hilbert posed the *Entscheidungsproblem*, just examples.

Common features of the examples:

- finite description of the procedure in terms of elementary operations
- deterministic (next step uniquely determined if there is one)
- procedure may not terminate on some input data, but we can recognize when it does terminate and what the result is.

E.g. multiply two decimal digits by looking up their product in a table.
Register Machine computation abstracts away from any particular, concrete representation of numbers (e.g. as bit strings) and the associated elementary operations of increment/decrement/zero-test.

Turing’s original model of computation (now called a Turing machine) is more concrete: even numbers have to be represented in terms of a fixed finite alphabet of symbols and increment/decrement/zero-test programmed in terms of more elementary symbol-manipulating operations.

Turing machines, informally

- Machine is in one of a finite set of states
- Tape symbol being scanned by tape head
- Special left endmarker symbol
- Special blank symbol
- Linear tape, unbounded to right, divided into cells containing a symbol from a finite alphabet of tape symbols. Only finitely many cells contain non-blank symbols.
Turing machines, informally

Machine starts with tape head pointing to the special left endmarker ▷.

Machine computes in discrete steps, each of which depends only on current state \((q)\) and symbol being scanned by tape head \((\text{0})\).

Action at each step is to overwrite the current tape cell with a symbol, move left or right one cell, or stay stationary, and change state.

Turing Machines

are specified by:

- \(Q\), finite set of machine states
- \(\Sigma\), finite set of tape symbols (disjoint from \(Q\)) containing distinguished symbols ▷ (left endmarker) and \(\_\) (blank)
- \(s \in Q\), an initial state
- \(\delta \in (Q \times \Sigma) \rightarrow (Q \cup \{\text{acc, rej}\}) \times \Sigma \times \{L, R, S\}\), a transition function, satisfying:

\[
\text{for all } q \in Q, \text{ there exists } q' \in Q \cup \{\text{acc, rej}\} \text{ with } \delta(q, \_ ) = (q', \_, R)
\]

(i.e. left endmarker is never overwritten and machine always moves to the right when scanning it)
Example Turing Machine

\[ M = (Q, \Sigma, s, \delta) \]

where

states \( Q = \{s, q, q'\} \) (s initial)
symbols \( \Sigma = \{\uparrow, \uparrow, 0, 1\} \)

transition function

\[ \delta \in (Q \times \Sigma) \rightarrow (Q \cup \{\text{acc}, \text{rej}\}) \times \Sigma \times \{L, R, S\} : \]

<table>
<thead>
<tr>
<th>( \delta )</th>
<th>( \uparrow )</th>
<th>( \uparrow )</th>
<th>( 0 )</th>
<th>( 1 )</th>

</table>

Turing machine computation

Turing machine configuration: \((q, w, u)\)

where

- \( q \in Q \cup \{\text{acc}, \text{rej}\} \) = current state
- \( w \) = non-empty string \((w = va)\) of tape symbols under and to the left of tape head, whose last element \((a)\) is contents of cell under tape head
- \( u \) = (possibly empty) string of tape symbols to the right of tape head (up to some point beyond which all symbols are \(\uparrow\))

Initial configurations: \((s, \uparrow, u)\)
Turing machine computation

Given a TM $M = (Q, \Sigma, s, \delta)$, we write

$$(q, w, u) \rightarrow_M (q', w', u')$$

to mean $q \neq \text{acc, rej}$, $w = va$ (for some $v, a$) and

- either $\delta(q, a) = (q', a', L)$, $w' = v$, and $u' = a'u$
- or $\delta(q, a) = (q', a', S)$, $w' = va'$ and $u' = u$
- or $\delta(q, a) = (q', a', R)$, $u = a'u''$ is non-empty, $w' = va'a''$ and $u' = u''$
- or $\delta(q, a) = (q', a', R)$, $u = \epsilon$ is empty, $w' = va' \cup$ and $u' = \epsilon$.

Turing machine computation

A computation of a TM $M$ is a (finite or infinite) sequence of configurations $c_0, c_1, c_2, \ldots$

where

- $c_0 = (s, \triangleright, u)$ is an initial configuration
- $c_i \rightarrow_M c_{i+1}$ holds for each $i = 0, 1, \ldots$. 

The computation

- does not halt if the sequence is infinite
- halts if the sequence is finite and its last element is of the form $(\text{acc}, w, u)$ or $(\text{rej}, w, u)$. 
Example Turing Machine

\[ M = (Q, \Sigma, s, \delta) \] where

states \( Q = \{s, q, q'\} \) (s initial)
symbols \( \Sigma = \{\uparrow, \downarrow, 0, 1\} \)

transition function

\[ \delta \in (Q \times \Sigma) \rightarrow (Q \cup \{\text{acc}, \text{rej}\}) \times \Sigma \times \{L, R, S\}: \]

<table>
<thead>
<tr>
<th></th>
<th>(\uparrow)</th>
<th>(\downarrow)</th>
<th>0</th>
<th>1</th>
</tr>
</thead>
<tbody>
<tr>
<td>s</td>
<td>(s, (\uparrow), R)</td>
<td>(q, (\downarrow), R)</td>
<td>(\text{rej}, 0, s)</td>
<td>(\text{rej}, 1, s)</td>
</tr>
<tr>
<td>q</td>
<td>(\text{rej}, \uparrow, R)</td>
<td>(q', 0, L)</td>
<td>(q, 1, R)</td>
<td>(q, 1, R)</td>
</tr>
<tr>
<td>q'</td>
<td>(\text{rej}, \uparrow, R)</td>
<td>(acc, (\downarrow), S)</td>
<td>(\text{rej}, 0, S)</td>
<td>(q', 1, L)</td>
</tr>
</tbody>
</table>

Claim: the computation of \( M \) starting from configuration \((s, \uparrow, \downarrow, 1^n 0)\) halts in configuration \((\text{acc}, \uparrow, 1^{n+1} 0)\).

The computation of \( M \) starting from configuration \((s, \uparrow, \downarrow, 1^n 0)\):

\[
\begin{align*}
(s, \uparrow, \downarrow, 1^n 0) & \quad \rightarrow_M (s, \uparrow, 1^n 0) \\
& \quad \rightarrow_M (q, \uparrow, 1^n, 0) \\
& \quad \vdots \\
& \quad \rightarrow_M (q, \uparrow, 1^n, 0) \\
& \quad \rightarrow_M (q, \uparrow, 1^{n+1}, \varepsilon) \\
& \quad \vdots \\
& \quad \rightarrow_M (q', \uparrow, 1^{n+1}, 0) \\
& \quad \rightarrow_M (\text{acc}, \uparrow, 1^{n+1} 0)
\end{align*}
\]
Theorem. The computation of a Turing machine $M$ can be implemented by a register machine.

Proof (sketch).

Step 1: fix a numerical encoding of $M$'s states, tape symbols, tape contents and configurations.

Step 2: implement $M$'s transition function (finite table) using RM instructions on codes.

Step 3: implement a RM program to repeatedly carry out $\rightarrow_M$.

Step 1

- Identify states and tape symbols with particular numbers:

\[
\begin{align*}
\text{acc} &= 0 \\
\text{rej} &= 1 \\
Q &= \{2, 3, \ldots, n\} \\
\Sigma &= \{0, 1, \ldots, m\}
\end{align*}
\]

- Code configurations $c = (q, w, u)$ by:

\[
\lfloor c \rfloor = \lfloor q \rfloor \lfloor [a_n, \ldots, a_1] \rfloor \lfloor [b_1, \ldots, b_m] \rfloor
\]

where $w = a_1 \cdots a_n$ ($n > 0$) and $u = b_1 \cdots b_m$ ($m \geq 0$) say.
Step 2

Using registers

\[ Q = \text{current state} \]

\[ A = \text{current tape symbol} \]

\[ D = \text{current direction of tape head} \]

(with \( L = 0 \), \( R = 1 \) and \( S = 2 \), say)

one can turn the finite table of (argument,result)-pairs specifying \( \delta \) into a RM program

\[
\delta(Q, A, D) \rightarrow \delta(Q, A, D) \]

so that starting the program with \( Q = q, A = a, D = d \) (and all other registers zeroed), it halts with \( Q = q', A = a', D = d' \), where \( (q', a', d') = \delta(q, a) \).

Step 3

The next slide specifies a RM to carry out \( M \)'s computation. It uses registers

\[ C = \text{code of current configuration} \]

\[ W = \text{code of tape symbols at and left of tape head} \]

(reading right-to-left)

\[ U = \text{code of tape symbols right of tape head} \]

(reading left-to-right)

Starting with \( C \) containing the code of an initial configuration (and all other registers zeroed), the RM program halts if and only if \( M \) halts; and in that case \( C \) holds the code of the final configuration.
Recall:

**Definition.** $f \in \mathbb{N}^n \rightarrow \mathbb{N}$ is (register machine) computable if there is a register machine $M$ with at least $n + 1$ registers $R_0, R_1, \ldots, R_n$ (and maybe more) such that for all $(x_1, \ldots, x_n) \in \mathbb{N}^n$ and all $y \in \mathbb{N}$, the computation of $M$ starting with $R_0 = 0$, $R_1 = x_1$, $\ldots$, $R_n = x_n$ and all other registers set to 0, halts with $R_0 = y$ if and only if $f(x_1, \ldots, x_n) = y$. 
We’ve seen that a Turing machine’s computation can be implemented by a register machine.

The converse holds: the computation of a register machine can be implemented by a Turing machine.

To make sense of this, we first have to fix a tape representation of RM configurations and hence of numbers and lists of numbers.

---

**Tape encoding of lists of numbers**

**Definition.** A tape over $\Sigma = \{\triangleright, \sqcup, 0, 1\}$ codes a list of numbers if precisely two cells contain 0 and the only cells containing 1 occur between these.

Such tapes look like:

$$\triangleright \sqcup \cdots \sqcup 0 \underbrace{1 \cdots 1}_{n_1} \underbrace{1 \cdots 1}_{n_2} \cdots \underbrace{1 \cdots 10}_{n_k} \sqcup \cdots$$

which corresponds to the list $[n_1, n_2, \ldots, n_k]$. 
**Definition.** $f \in \mathbb{N}^n \rightarrow \mathbb{N}$ is Turing computable if and only if there is a Turing machine $M$ with the following property:

Starting $M$ from its initial state with tape head on the left endmarker of a tape coding $[0, x_1, \ldots, x_n]$, $M$ halts if and only if $f(x_1, \ldots, x_n) \downarrow$, and in that case the final tape codes a list (of length $\geq 1$) whose first element is $y$ where $f(x_1, \ldots, x_n) = y$.

**Theorem.** A partial function is Turing computable if and only if it is register machine computable.

**Proof (sketch).** We’ve seen how to implement any TM by a RM. Hence

$f$ TM computable implies $f$ RM computable.

For the converse, one has to implement the computation of a RM in terms of a TM operating on a tape coding RM configurations. To do this, one has to show how to carry out the action of each type of RM instruction on the tape. It should be reasonably clear that this is possible in principle, even if the details (omitted) are tedious.
Notions of computability

- Church (1936): \( \lambda \)-calculus [see later]
- Turing (1936): Turing machines.

Turing showed that the two very different approaches determine the same class of computable functions. Hence:

**Church-Turing Thesis.** Every algorithm [in intuitive sense of Lect. 1] can be realized as a Turing machine.

Further evidence for the thesis:

- Gödel and Kleene (1936): partial recursive functions
- Post (1943) and Markov (1951): canonical systems for generating the theorems of a formal system
- Lambek (1961) and Minsky (1961): register machines
- Variations on all of the above (e.g. multiple tapes, non-determinism, parallel execution...)

All have turned out to determine the same collection of computable functions.
Notions of computability

**Church-Turing Thesis.** Every algorithm [in intuitive sense of Lect. 1] can be realized as a Turing machine.

In rest of the course we’ll look at

- Gödel and Kleene (1936): partial recursive functions
  (⇝ branch of mathematics called recursion theory)
- Church (1936): \(\lambda\)-calculus
  (⇝ branch of CS called functional programming)

**Aim**

A more abstract, machine-independent description of the collection of computable partial functions than provided by register/Turing machines:

they form the smallest collection of partial functions containing some basic functions and closed under some fundamental operations for forming new functions from old—composition, primitive recursion and minimization.

The characterization is due to Kleene (1936), building on work of Gödel and Herbrand.
Basic functions

- **Projection functions**, $\text{proj}_i^n \in \mathbb{N}^n \rightarrow \mathbb{N}$:
  
  $$\text{proj}_i^n(x_1, \ldots, x_n) \triangleq x_i$$

- **Constant functions with value 0**, $\text{zero}^n \in \mathbb{N}^n \rightarrow \mathbb{N}$:
  
  $$\text{zero}^n(x_1, \ldots, x_n) \triangleq 0$$

- **Successor function**, $\text{succ} \in \mathbb{N} \rightarrow \mathbb{N}$:
  
  $$\text{succ}(x) \triangleq x + 1$$

Basic functions are all RM computable:

- **Projection** $\text{proj}_i^n$ is computed by
  
  $$\text{START} \rightarrow \mathbb{R}_0 ::= \mathbb{R}_i \rightarrow \text{HALT}$$

- **Constant** $\text{zero}^n$ is computed by
  
  $$\text{START} \rightarrow \text{HALT}$$

- **Successor** $\text{succ}$ is computed by
  
  $$\text{START} \rightarrow \mathbb{R}_1^+ \rightarrow \mathbb{R}_0 ::= \mathbb{R}_1 \rightarrow \text{HALT}$$
Composition

Composition of $f \in \mathbb{N}^n \rightarrow \mathbb{N}$ with $g_1, \ldots, g_n \in \mathbb{N}^m \rightarrow \mathbb{N}$ is the partial function $f \circ [g_1, \ldots, g_n] \in \mathbb{N}^m \rightarrow \mathbb{N}$ satisfying

$$f \circ [g_1, \ldots, g_n](x_1, \ldots, x_m) \equiv f(g_1(x_1, \ldots, x_m), \ldots, g_n(x_1, \ldots, x_m))$$

where $\equiv$ is “Kleene equivalence” of possibly-undefined expressions: LHS $\equiv$ RHS means “either both LHS and RHS are undefined, or they are both defined and are equal.”

So $f \circ [g_1, \ldots, g_n](x_1, \ldots, x_m) = z$ iff there exist $y_1, \ldots, y_n$ with $g_i(x_1, \ldots, x_m) = y_i$ (for $i = 1..n$) and $f(y_1, \ldots, y_n) = z$.

N.B. in case $n = 1$, we write $f \circ g_1$ for $f \circ [g_1]$. 
Composition

$f \circ [g_1, \ldots, g_n]$ is computable if $f$ and $g_1, \ldots, g_n$ are.

**Proof.** Given RM programs $\left\{ F \atop G_i \right\}$ computing $\left\{ f(y_1, \ldots, y_n) \atop g_i(x_1, \ldots, x_m) \right\}$ in $R_0$ starting with $\left\{ R_1, \ldots, R_n \atop R_1, \ldots, R_m \right\}$ set to $\left\{ y_1, \ldots, y_n \atop x_1, \ldots, x_m \right\}$, then the next slide specifies a RM program computing $f \circ [g_1, \ldots, g_n](x_1, \ldots, x_m)$ in $R_0$ starting with $R_1, \ldots, R_m$ set to $x_1, \ldots, x_m$.

(**Hygiene** [caused by the lack of local names for registers in the RM model of computation]: we assume the programs $F, G_1, \ldots, G_n$ only mention registers up to $R_N$ (where $N \geq \max\{n, m\}$) and that $X_1, \ldots, X_m, Y_1, \ldots, Y_n$ are some registers $R_i$ with $i > N$.)

\[
\begin{array}{cccc}
\text{START} & \quad & \text{START} & \quad & \text{START} \\
\hline
(x_1, \ldots, x_m) := (R_1, \ldots, R_m) & \rightarrow & G_1 & \rightarrow & Y_1 := R_0 & \rightarrow & (R_0, \ldots, R_N) := (0, \ldots, 0) \\
(R_1, \ldots, R_m) := (x_1, \ldots, x_m) & \rightarrow & G_2 & \rightarrow & Y_2 := R_0 & \rightarrow & (R_0, \ldots, R_N) := (0, \ldots, 0) \\
& \rightarrow & \cdots & \rightarrow & \cdots & \rightarrow & \cdots \\
(R_1, \ldots, R_m) := (x_1, \ldots, x_m) & \rightarrow & G_n & \rightarrow & Y_n := R_0 & \rightarrow & (R_0, \ldots, R_N) := (0, \ldots, 0) \\
(R_1, \ldots, R_n) := (Y_1, \ldots, Y_n) & \rightarrow & F \\
\end{array}
\]
Partial Recursive Functions

Aim

A more abstract, machine-independent description of the collection of computable partial functions than provided by register/Turing machines:

they form the smallest collection of partial functions containing some basic functions and closed under some fundamental operations for forming new functions from old—composition, primitive recursion and minimization.

The characterization is due to Kleene (1936), building on work of Gödel and Herbrand.
Examples of recursive definitions

\[
\begin{align*}
\begin{cases}
  f_1(0) & \equiv 0 \\
  f_1(x+1) & \equiv f_1(x) + (x+1)
\end{cases}
& \quad f_1(x) = \text{sum of } 0,1,2,\ldots,x \\
\begin{cases}
  f_2(0) & \equiv 0 \\
  f_2(1) & \equiv 1 \\
  f_2(x+2) & \equiv f_2(x) + f_2(x+1)
\end{cases}
& \quad f_2(x) = \text{xth Fibonacci number} \\
\begin{cases}
  f_3(0) & \equiv 0 \\
  f_3(x+1) & \equiv f_3(x+2) + 1
\end{cases}
& \quad f_3(x) \text{ undefined except when } x = 0 \\
\begin{align*}
  f_4(x) & \equiv \begin{cases}
  if & x > 100 \text{ then } x - 10 \\
  else & f_4(f_4(x + 11))
\end{cases}
& \quad f_4 \text{ is McCarthy’s } "91 \text{ function", which maps } x \text{ to } 91 \text{ if } x \leq 100 \text{ and to } x - 10 \text{ otherwise}
\end{align*}
\]

Computation Theory, L 8 103/169

Primitive recursion

**Theorem.** Given \( f \in \mathbb{N}^n \rightarrow \mathbb{N} \) and \( g \in \mathbb{N}^{n+2} \rightarrow \mathbb{N} \), there is a unique \( h \in \mathbb{N}^{n+1} \rightarrow \mathbb{N} \) satisfying

\[
\begin{align*}
  h(\bar{x},0) & \equiv f(\bar{x}) \\
  h(\bar{x},x+1) & \equiv g(\bar{x},x,h(\bar{x},x))
\end{align*}
\]

for all \( \bar{x} \in \mathbb{N}^n \) and \( x \in \mathbb{N} \).

We write \( \rho^n(f,g) \) for \( h \) and call it the partial function defined by primitive recursion from \( f \) and \( g \).
**Theorem.** Given $f \in \mathbb{N}^n \rightarrow \mathbb{N}$ and $g \in \mathbb{N}^{n+2} \rightarrow \mathbb{N}$, there is a unique $h \in \mathbb{N}^{n+1} \rightarrow \mathbb{N}$ satisfying

$$
\begin{align*}
(*): \quad & h(\vec{x},0) \equiv f(\vec{x}) \\
& h(\vec{x},x+1) \equiv g(\vec{x},x,h(\vec{x},x))
\end{align*}
$$

for all $\vec{x} \in \mathbb{N}^n$ and $x \in \mathbb{N}$.

**Proof (sketch).** *Existence:* the set

$$
\begin{align*}
h(\vec{x},x,y) \in \mathbb{N}^{n+2} \mid \exists y_0, y_1, \ldots, y_x \\
f(\vec{x}) = y_0 \land (\bigwedge_{i=0}^{x-1} g(\vec{x},i,y_i) = y_{i+1}) \land y_x = y
\end{align*}
$$

defines a partial function satisfying $(*)$.

*Uniqueness:* if $h$ and $h'$ both satisfy $(*)$, then one can prove by induction on $x$ that $\forall \vec{x} \ (h(\vec{x},x) = h'(\vec{x},x))$.

**Example:** addition

Addition $add \in \mathbb{N}^2 \rightarrow \mathbb{N}$ satisfies:

$$
\begin{align*}
add(x_1,0) & \equiv x_1 \\
add(x_1,x+1) & \equiv add(x_1,x) + 1
\end{align*}
$$

So $add = \rho^1(f,g)$ where

$$
\begin{align*}
f(x_1) & \triangleq x_1 \\
g(x_1,x_2,x_3) & \triangleq x_3 + 1
\end{align*}
$$

Note that $f = \text{proj}_1^1$ and $g = \text{succ} \circ \text{proj}_3^3$; so $add$ can be built up from basic functions using composition and primitive recursion: $add = \rho^1(\text{proj}_1^1, \text{succ} \circ \text{proj}_3^3)$.
Example: predecessor

Predecessor $pred \in \mathbb{N} \rightarrow \mathbb{N}$ satisfies:

\[
\begin{align*}
    pred(0) & \equiv 0 \\
    pred(x + 1) & \equiv x
\end{align*}
\]

So $pred = \rho^0(f, g)$ where \[
\begin{align*}
    f() & \triangleq 0 \\
    g(x_1, x_2) & \triangleq x_1
\end{align*}
\]

Thus $pred$ can be built up from basic functions using primitive recursion: $pred = \rho^0(\text{zero}^0, \text{proj}^2_1)$.

Example: multiplication

Multiplication $mult \in \mathbb{N}^2 \rightarrow \mathbb{N}$ satisfies:

\[
\begin{align*}
    mult(x_1, 0) & \equiv 0 \\
    mult(x_1, x + 1) & \equiv mult(x_1, x) + x_1
\end{align*}
\]

and thus $mult = \rho^1(\text{zero}^1, \text{add} \circ (\text{proj}^3_3, \text{proj}^3_1))$.

So $mult$ can be built up from basic functions using composition and primitive recursion (since $\text{add}$ can be).
Definition. A [partial] function \( f \) is primitive recursive \((f \in \text{PRIM})\) if it can be built up in finitely many steps from the basic functions by use of the operations of composition and primitive recursion.

In other words, the set \( \text{PRIM} \) of primitive recursive functions is the smallest set (with respect to subset inclusion) of partial functions containing the basic functions and closed under the operations of composition and primitive recursion.

Every \( f \in \text{PRIM} \) is a total function, because:

- all the basic functions are total
- if \( f, g_1, \ldots, g_n \) are total, then so is \( f \circ (g_1, \ldots, g_n) \) [why?]
- if \( f \) and \( g \) are total, then so is \( \rho^n(f, g) \) [why?]
**Definition.** A [partial] function \( f \) is primitive recursive \((f \in \text{PRIM})\) if it can be built up in finitely many steps from the basic functions by use of the operations of composition and primitive recursion.

**Theorem.** Every \( f \in \text{PRIM} \) is computable.

**Proof.** Already proved: basic functions are computable; composition preserves computability. So just have to show:

\[ \rho^n(f, g) \in \mathbb{N}^{n+1} \rightarrow \mathbb{N} \text{ computable if } f \in \mathbb{N}^n \rightarrow \mathbb{N} \text{ and } g \in \mathbb{N}^{n+1} \rightarrow \mathbb{N} \text{ are.} \]

Suppose \( f \) and \( g \) are computed by RM programs \( F \) and \( G \) (with our usual I/O conventions). Then the RM specified on the next slide computes \( \rho^n(f, g) \). (We assume \( x_1, \ldots, x_{n+1}, C \) are some registers not mentioned in \( F \) and \( G \); and that the latter only use registers \( R_0, \ldots, R_N \), where \( N \geq n + 2 \).)

Aim

A more abstract, machine-independent description of the collection of computable partial functions than provided by register/Turing machines:

they form the smallest collection of partial functions containing some basic functions and closed under some fundamental operations for forming new functions from old—composition, primitive recursion and minimization.

The characterization is due to Kleene (1936), building on work of Gödel and Herbrand.

Minimization

Given a partial function \( f \in \mathbb{N}^{n+1} \to \mathbb{N} \), define

\[ \mu^n f \in \mathbb{N}^n \to \mathbb{N} \] by

\[ \mu^n f(\bar{x}) \triangleq \text{least } x \text{ such that } f(\bar{x}, x) = 0 \]

and for each \( i = 0, \ldots, x - 1 \),

\( f(\bar{x}, i) \) is defined and \( > 0 \)

(undefined if there is no such \( x \))

In other words

\[ \mu^n f = \{(\bar{x}, x) \in \mathbb{N}^{n+1} | \exists y_0, \ldots, y_x \] \[ \left( \bigwedge_{i=0}^{x} f(\bar{x}, i) = y_i \right) \land \left( \bigwedge_{i=0}^{x-1} y_i > 0 \right) \land y_x = 0 \} \]
Example of minimization

\[ \text{integer part of } \frac{x_1}{x_2} \equiv \text{least } x_3 \text{ such that } x_1 < x_2(x_3 + 1) \]

(undef. if \( x_2 = 0 \))

\[ \equiv \mu^2 f(x_1, x_2) \]

where \( f \in \mathbb{N}^3 \rightarrow \mathbb{N} \) is

\[
f(x_1, x_2, x_3) \triangleq \begin{cases} 
1 & \text{if } x_1 \geq x_2(x_3 + 1) \\
0 & \text{if } x_1 < x_2(x_3 + 1)
\end{cases}
\]

**Definition.** A partial function \( f \) is partial recursive (\( f \in \text{PR} \)) if it can be built up in finitely many steps from the basic functions by use of the operations of composition, primitive recursion and minimization.

In other words, the set \( \text{PR} \) of partial recursive functions is the smallest set (with respect to subset inclusion) of partial functions containing the basic functions and closed under the operations of composition, primitive recursion and minimization.
**Definition.** A partial function $f$ is partial recursive ($f \in \text{PR}$) if it can be built up in finitely many steps from the basic functions by use of the operations of composition, primitive recursion and minimization.

**Theorem.** Every $f \in \text{PR}$ is computable.

**Proof.** Just have to show:

μ$^n$ $f \in \mathbb{N}^n \rightarrow \mathbb{N}$ is computable if $f \in \mathbb{N}^{n+1} \rightarrow \mathbb{N}$ is.

Suppose $f$ is computed by RM program $F$ (with our usual I/O conventions). Then the RM specified on the next slide computes $\mu^n f$. (We assume $X_1, \ldots, X_n, C$ are some registers not mentioned in $F$; and that the latter only uses registers $R_0, \ldots, R_N$, where $N \geq n + 1$.)
Computable = partial recursive

**Theorem.** Not only is every \( f \in \text{PR} \) computable, but conversely, every computable partial function is partial recursive.

**Proof (sketch).** Let \( f \) be computed by RM \( M \). Recall how we coded instantaneous configurations \( c = (\ell, r_0, \ldots, r_n) \) of \( M \) as numbers \( \lceil \ell, r_0, \ldots, r_n \rceil \). It is possible to construct primitive recursive functions \( \text{lab}, \text{val}_0, \text{next}_M \in \mathbb{N} \rightarrow \mathbb{N} \) satisfying

\[
\begin{align*}
\text{lab}(\lceil \ell, r_0, \ldots, r_n \rceil) &= \ell \\
\text{val}_0(\lceil \ell, r_0, \ldots, r_n \rceil) &= r_0 \\
\text{next}_M(\lceil \ell, r_0, \ldots, r_n \rceil) &= \text{code of } M's \text{ next configuration}
\end{align*}
\]

(Showing that \( \text{next}_M \in \text{PRIM} \) is tricky—proof omitted.)

**Proof sketch, cont.**

Let \( \text{config}_M(\vec{x}, t) \) be the code of \( M \)'s configuration after \( t \) steps, starting with initial register values \( \vec{x} \). It’s in \( \text{PRIM} \) because:

\[
\begin{align*}
\text{config}_M(\vec{x}, 0) &= \lceil 0, \vec{x} \rceil \\
\text{config}_M(\vec{x}, t + 1) &= \text{next}_M(\text{config}_M(\vec{x}, t))
\end{align*}
\]

Can assume \( M \) has a single \text{HALT} as last instruction, \( I \)th say (and no erroneous halts). Let \( \text{halt}_M(\vec{x}) \) be the number of steps \( M \) takes to halt when started with initial register values \( \vec{x} \) (undefined if \( M \) does not halt). It satisfies

\[
\text{halt}_M(\vec{x}) \equiv \text{least } t \text{ such that } I - \text{lab}(\text{config}_M(\vec{x}, t)) = 0
\]

and hence is in \( \text{PR} \) (because \( \text{lab}, \text{config}_M, I - ( ) \in \text{PRIM} \)).

So \( f \in \text{PR} \), because \( f(\vec{x}) \equiv \text{val}_0(\text{config}_M(\vec{x}, \text{halt}_M(\vec{x}))) \).
Definition. A partial function $f$ is partial recursive ($f \in \text{PR}$) if it can be built up in finitely many steps from the basic functions by use of the operations of composition, primitive recursion and minimization.

The members of PR that are total are called recursive functions.

Fact: there are recursive functions that are not primitive recursive. For example. . .

Ackermann’s function

There is a (unique) function $ack \in \mathbb{N}^2 \rightarrow \mathbb{N}$ satisfying

$$
\begin{align*}
ack(0, x_2) &= x_2 + 1 \\
ack(x_1 + 1, 0) &= \ack(x_1, 1) \\
ack(x_1 + 1, x_2 + 1) &= \ack(x_1, \ack(x_1 + 1, x_2))
\end{align*}
$$

- $\ack$ is computable, hence recursive [proof: exercise].
- Fact: $\ack$ grows faster than any primitive recursive function $f \in \mathbb{N}^2 \rightarrow \mathbb{N}$:

  $$
  \exists N_f \forall x_1, x_2 > N_f \ (f(x_1, x_2) < \ack(x_1, x_2)).
  $$

  Hence $\ack$ is not primitive recursive.
Lambda-Calculus

Notions of computability

- Church (1936): $\lambda$-calculus
- Turing (1936): Turing machines.

Turing showed that the two very different approaches determine the same class of computable functions. Hence:

**Church-Turing Thesis.** Every algorithm [in intuitive sense of Lect. 1] can be realized as a Turing machine.
λ-Terms, $M$

are built up from a given, countable collection of

- variables $x, y, z, \ldots$

by two operations for forming $\lambda$-terms:

- $\lambda$-abstraction: $(\lambda x.M)$
  (where $x$ is a variable and $M$ is a $\lambda$-term)

- application: $(M M')$
  (where $M$ and $M'$ are $\lambda$-terms).

Some random examples of $\lambda$-terms:

\[
x (\lambda x.x) ((\lambda y.(xy))x) (\lambda y.((\lambda y.(xy))x))
\]
Free and bound variables

In $\lambda x. M$, we call $x$ the **bound variable** and $M$ the body of the $\lambda$-abstraction.

An occurrence of $x$ in a $\lambda$-term $M$ is called

- binding if in between $\lambda$ and .
  (e.g. $(\lambda x. y) x$)
- bound if in the body of a binding occurrence of $x$
  (e.g. $(\lambda x. y) x$)
- free if neither binding nor bound
  (e.g. $(\lambda x. y) x$).

Sets of free and bound variables:

\[
\begin{align*}
FV(x) &= \{x\} \\
FV(\lambda x. M) &= FV(M) - \{x\} \\
FV(M N) &= FV(M) \cup FV(N) \\
BV(x) &= \emptyset \\
BV(\lambda x. M) &= BV(M) \cup \{x\} \\
BV(M N) &= BV(M) \cup BV(N)
\end{align*}
\]

If $FV(M) = \emptyset$, $M$ is called a closed term, or combinator.
\(\alpha\text{-Equivalence } M =_\alpha M'\)

\(\lambda x. M\) is intended to represent the function \(f\) such that \(f(x) = M\) for all \(x\).

So the name of the bound variable is immaterial: if \(M' = M\{x'/x\}\) is the result of taking \(M\) and changing all occurrences of \(x\) to some variable \(x' \neq M\), then \(\lambda x. M\) and \(\lambda x'. M'\) both represent the same function.

For example, \(\lambda x.x\) and \(\lambda y.y\) represent the same function (the identity function).

\(\alpha\text{-Equivalence } M =_\alpha M'\)

is the binary relation inductively generated by the rules:

\[
\begin{array}{c}
\frac{}{x =_\alpha x} \\
\frac{z \not= (MN)}{M[z/x] =_\alpha N[z/y]} \\
\frac{\lambda x. M}{\lambda y. N} \\
\frac{M =_\alpha M'}{MN =_\alpha M'N'} \\
\frac{N =_\alpha N'}{MN =_\alpha M'N'}
\end{array}
\]

where \(M[z/x]\) is \(M\) with all occurrences of \(x\) replaced by \(z\).
**α-Equivalence** \( M =_\alpha M' \)

For example:

\[
\lambda x. (\lambda x'. x) x' =_\alpha \lambda y. (\lambda x x'. x) x'
\]

because

\[
(\lambda z x'. z) x' =_\alpha (\lambda x x'. x) x'
\]

because

\[
\lambda z x'. z =_\alpha \lambda x x'. x \quad \text{and} \quad x' =_\alpha x'
\]

because

\[
\lambda x'. u =_\alpha \lambda x'. u \quad \text{and} \quad x' =_\alpha x'
\]

because

\[
u =_\alpha u \quad \text{and} \quad x' =_\alpha x'.\]

---

**Fact:** \( =_\alpha \) is an equivalence relation (reflexive, symmetric and transitive).

We do not care about the particular names of bound variables, just about the distinctions between them. So \( \alpha \)-equivalence classes of \( \lambda \)-terms are more important than \( \lambda \)-terms themselves.

- Textbooks (and these lectures) suppress any notation for \( \alpha \)-equivalence classes and refer to an equivalence class via a representative \( \lambda \)-term (look for phrases like “we identify terms up to \( \alpha \)-equivalence” or “we work up to \( \alpha \)-equivalence”).

- For implementations and computer-assisted reasoning, there are various devices for picking canonical representatives of \( \alpha \)-equivalence classes (e.g. de Bruijn indexes, graphical representations, . . .).
Substitution $N[M/x]$

\[
\begin{align*}
    x[M/x] &= M \\
    y[M/x] &= y & \text{if } y \neq x \\
    (\lambda y.N)[M/x] &= \lambda y.N[M/x] & \text{if } y \not\in (Mx) \\
    (N_1 N_2)[M/x] &= N_1[M/x] N_2[M/x]
\end{align*}
\]

Side-condition $y \not\in (Mx)$ ($y$ does not occur in $M$ and $y \neq x$) makes substitution “capture-avoiding”.

E.g. if $x \neq y$

\[
(\lambda y.x)[y/x] \neq \lambda y.y
\]

\[N \mapsto N[M/x]\] induces a total operation on $\alpha$-equivalence classes.
Recall that $\lambda x. M$ is intended to represent the function $f$ such that $f(x) = M$ for all $x$. We can regard $\lambda x. M$ as a function on $\lambda$-terms via substitution: map each $N$ to $M[N/x]$.

So the natural notion of computation for $\lambda$-terms is given by stepping from a $\beta$-redex $(\lambda x. M) N$ to the corresponding $\beta$-reduct $M[N/x]$.

**One-step $\beta$-reduction, $M \rightarrow M'$:**

\[
\begin{align*}
(\lambda x. M) N & \rightarrow M[N/x] \\
\lambda x. M & \rightarrow \lambda x. M' \\
M & \rightarrow M' \\
M N & \rightarrow M' N \\
N M & \rightarrow N M' \\
N & \rightarrow N' \\
M' & \rightarrow \alpha N'
\end{align*}
\]
**β-Reduction**

E.g.

\[
((\lambda y.\lambda z.z)u)y \\
(\lambda x.\,\,y)((\lambda y.\lambda z.z)u) \\
(\lambda x.\,\,y)(\lambda z.z)
\]

E.g. of “up to α-equivalence” aspect of reduction:

\[
(\lambda x.\lambda y.x)y =_\alpha (\lambda x.\lambda z.x)y \rightarrow \lambda z.y
\]

Many-step β-reduction, \( M \rightarrow M' \):

<table>
<thead>
<tr>
<th>( M =_\alpha M' )</th>
<th>( M \rightarrow M' )</th>
<th>( M \rightarrow M' )</th>
<th>( M' \rightarrow M'' )</th>
</tr>
</thead>
<tbody>
<tr>
<td>(no steps)</td>
<td>(1 step)</td>
<td></td>
<td>(1 more step)</td>
</tr>
</tbody>
</table>

E.g.

\[
(\lambda x.\,\,y)((\lambda y.\,\,z.z)u) \rightarrow y \\
(\lambda x.\lambda y.x)y \rightarrow \lambda z.y
\]
Lambda-Definable Functions

**β-Conversion $M =_\beta N$**

Informally: $M =_\beta N$ holds if $N$ can be obtained from $M$ by performing zero or more steps of $\alpha$-equivalence, $\beta$-reduction, or $\beta$-expansion ($=$ inverse of a reduction).

E.g. $u ((\lambda x y . v x) y) =_\beta (\lambda x . u x) (\lambda x . v y)$

because $(\lambda x . u x) (\lambda x . v y) \rightarrow u (\lambda x . v y)$

and so we have

$$
\begin{align*}
  u ((\lambda x y . v x) y) & =_\alpha u ((\lambda x y' . v x) y) \\
  & \rightarrow u (\lambda y' . v y) \quad \text{reduction} \\
  & =_\alpha u (\lambda x . v y) \\
  & \leftarrow (\lambda x . u x) (\lambda x . v y) \quad \text{expansion}
\end{align*}
$$
\[ \beta\text{-Conversion } M = \beta N \]

is the binary relation inductively generated by the rules:

\[
\begin{align*}
M = \alpha M' & \quad M \rightarrow M' & \quad M = \beta M' \\
M = \beta M' & \quad M' = \beta M'' & \quad M = \beta M' \\
M = \beta M' & \quad N = \beta N' & \quad MN = \beta M'N'
\end{align*}
\]

\textbf{Church-Rosser Theorem}

\textbf{Theorem.} \( \rightarrow \) is confluent, that is, if \( M_1 \leftarrow M \rightarrow M_2 \), then there exists \( M' \) such that \( M_1 \rightarrow M' \leftarrow M_2 \).

\textbf{Corollary.} \( M_1 = \beta M_2 \) iff \( \exists M \ (M_1 \rightarrow M \leftarrow M_2) \).

\textbf{Proof.} \( = \beta \) satisfies the rules generating \( \rightarrow \); so \( M \rightarrow M' \) implies \( M = \beta M' \). Thus if \( M_1 \rightarrow M \leftarrow M_2 \), then \( M_1 = \beta M = \beta M_2 \) and so \( M_1 = \beta M_2 \).

Conversely, the relation \( \{(M_1, M_2) \mid \exists M \ (M_1 \rightarrow M \leftarrow M_2)\} \) satisfies the rules generating \( = \beta \): the only difficult case is closure of the relation under transitivity and for this we use the Church-Rosser theorem. Hence \( M_1 = \beta M_2 \) implies \( \exists M \ (M_1 \rightarrow M' \leftarrow M_2) \).
**β-Normal Forms**

**Definition.** A λ-term \( N \) is in \( β \)-normal form (nf) if it contains no \( β \)-redexes (no sub-terms of the form \((λx.M)M'\)). \( M \) has \( β \)-nf \( N \) if \( M \equiv_β N \) with \( N \) a \( β \)-nf.

Note that if \( N \) is a \( β \)-nf and \( N \rightarrow N' \), then it must be that \( N =_α N' \) (why?).

Hence if \( N_1 =_β N_2 \) with \( N_1 \) and \( N_2 \) both \( β \)-nfs, then \( N_1 =_α N_2 \).
(For if \( N_1 =_β N_2 \), then \( N_1 \leftarrow M \rightarrow N_2 \) for some \( M \); hence by Church-Rosser, \( N_1 \rightarrow M' \leftarrow N_2 \) for some \( M' \), so \( N_1 =_α M' =_α N_2 \).)

So the \( β \)-nf of \( M \) is unique up to \( α \)-equivalence if it exists.

---

**Non-termination**

Some \( λ \) terms have no \( β \)-nf.

E.g. \( Ω \triangleq (λx.x)x)(λx.x) \) satisfies

- \( Ω \rightarrow (x)x[(λx.x)x/x] = Ω \),
- \( Ω \rightarrow M \) implies \( Ω =_α M \).

So there is no \( β \)-nf \( N \) such that \( Ω =_β N \).

A term can possess both a \( β \)-nf and infinite chains of reduction from it.

E.g. \((λx.y)Ω \rightarrow y \), but also \((λx.y)Ω \rightarrow (λx.y)Ω \rightarrow \cdots \).
Non-termination

Normal-order reduction is a deterministic strategy for reducing $\lambda$-terms: reduce the “left-most, outer-most” redex first.

- left-most: reduce $M$ before $N$ in $MN$, and then
- outer-most: reduce $(\lambda x.M)N$ rather than either of $M$ or $N$.

(cf. call-by-name evaluation).

**Fact:** normal-order reduction of $M$ always reaches the $\beta$-nf of $M$ if it possesses one.

---

Encoding data in $\lambda$-calculus

Computation in $\lambda$-calculus is given by $\beta$-reduction. To relate this to register/Turing-machine computation, or to partial recursive functions, we first have to see how to encode numbers, pairs, lists, ... as $\lambda$-terms.

We will use the original encoding of numbers due to Church...
Church’s numerals

\[\begin{align*}
0 & \triangleq \lambda f \, x. x \\
1 & \triangleq \lambda f \, x. f \, x \\
2 & \triangleq \lambda f \, x. f(f \, x) \\
& \vdots \\
n & \triangleq \lambda f \, x. f(\cdots(f \, x)\cdots) \\
& \text{\(n\) times}
\end{align*}\]

Notation: \[
\begin{align*}
M^0 N & \triangleq N \\
M^1 N & \triangleq MN \\
M^{n+1} N & \triangleq M(M^n N)
\end{align*}
\]

so we can write \(n\) as \(\lambda f \, x. f^n x\) and we have \(\underbrace{n \, M \, N = \beta \, M^n \, N}\).

\[\text{Computation Theory , L 11} \quad 147/170\]

\[\text{\(\lambda\)-Definable functions}\]

**Definition.** \(f \in \mathbb{N}^n \rightarrow \mathbb{N}\) is \(\lambda\)-definable if there is a closed \(\lambda\)-term \(F\) that represents it: for all \((x_1, \ldots, x_n) \in \mathbb{N}^n\) and \(y \in \mathbb{N}\)

- if \(f(x_1, \ldots, x_n) = y\), then \(F_{x_1} \cdots x_n = \beta \, y\)
- if \(f(x_1, \ldots, x_n) \uparrow\), then \(F_{x_1} \cdots x_n\) has no \(\beta\)-nf.

For example, addition is \(\lambda\)-definable because it is represented by \(P \triangleq \lambda x_1 \, x_2. \lambda f \, x. x_1 \, f(x_2 \, f \, x)\):

\[
\begin{align*}
P\, m \, n & = \beta \, \lambda f \, x. \, m \, f(n \, f \, x) \\
& = \beta \, \lambda f \, x. \, m \, f(f^n x) \\
& = \beta \, \lambda f \, x. \, f^m(f^n x) \\
& = \lambda f \, x. \, f^{m+n} x \\
& = m + n
\end{align*}
\]

\[\text{Computation Theory , L 11} \quad 148/171\]
Computable = $\lambda$-definable

**Theorem.** A partial function is computable if and only if it is $\lambda$-definable.

We already know that

- Register Machine computable
- Turing computable
- partial recursive.

Using this, we break the theorem into two parts:

- every partial recursive function is $\lambda$-definable
- $\lambda$-definable functions are RM computable

**$\lambda$-Definable functions**

**Definition.** $f \in \mathbb{N}^n \rightarrow \mathbb{N}$ is $\lambda$-definable if there is a closed $\lambda$-term $F$ that represents it: for all $(x_1, \ldots, x_n) \in \mathbb{N}^n$ and $y \in \mathbb{N}$

- if $f(x_1, \ldots, x_n) = y$, then $F\overline{x_1} \cdots \overline{x_n} = \beta y$
- if $f(x_1, \ldots, x_n) \uparrow$, then $F\overline{x_1} \cdots \overline{x_n}$ has no $\beta$-nf.

This condition can make it quite tricky to find a $\lambda$-term representing a non-total function.

For now, we concentrate on total functions. First, let us see why the elements of PRIM (primitive recursive functions) are $\lambda$-definable.
Basic functions

- **Projection functions**, \( \text{proj}^n_i \in \mathbb{N}^n \rightarrow \mathbb{N} \):
  \[
  \text{proj}^n_i(x_1, \ldots, x_n) \triangleq x_i
  \]

- **Constant functions with value 0**, \( \text{zero}^n \in \mathbb{N}^n \rightarrow \mathbb{N} \):
  \[
  \text{zero}^n(x_1, \ldots, x_n) \triangleq 0
  \]

- **Successor function**, \( \text{succ} \in \mathbb{N} \rightarrow \mathbb{N} \):
  \[
  \text{succ}(x) \triangleq x + 1
  \]

Basic functions are representable

- \( \text{proj}^n_i \in \mathbb{N}^n \rightarrow \mathbb{N} \) is represented by \( \lambda x_1 \ldots x_n.x_i \)
- \( \text{zero}^n \in \mathbb{N}^n \rightarrow \mathbb{N} \) is represented by \( \lambda x_1 \ldots x_n.0 \)
- \( \text{succ} \in \mathbb{N} \rightarrow \mathbb{N} \) is represented by
  \[
  \text{Succ} \triangleq \lambda x_1 \, f \, x. \, f \,(x_1 \, f \, x)
  \]
since

\[
\text{Succ} \, n = \beta \lambda f \, x. \, f \,(n \, f \, x)
= \beta \lambda f \, x. \, f \,(f^n \, x)
= \lambda f \, x. \, f^{n+1} \, x
= n + 1
\]
Representing composition

If total function $f \in \mathbb{N}^n \rightarrow \mathbb{N}$ is represented by $F$ and total functions $g_1, \ldots, g_n \in \mathbb{N}^m \rightarrow \mathbb{N}$ are represented by $G_1, \ldots, G_n$, then their composition $f \circ (g_1, \ldots, g_n) \in \mathbb{N}^m \rightarrow \mathbb{N}$ is represented simply by

$$\lambda x_1 \ldots x_m. F (G_1 x_1 \ldots x_m) \ldots (G_n x_1 \ldots x_m)$$

because

$$F (G_1 a_1 \ldots a_m) \ldots (G_n a_1 \ldots a_m) \rightarrow^\beta f (g_1(a_1, \ldots, a_m), \ldots, g_n(a_1, \ldots, a_m)) = f \circ (g_1, \ldots, g_n)(a_1, \ldots, a_m)$$

This does not necessarily work for partial functions. E.g. totally undefined function $u \in \mathbb{N} \rightarrow \mathbb{N}$ is represented by $U \triangleq \lambda x_1. \Omega$ (why?) and zero$^1 \in \mathbb{N} \rightarrow \mathbb{N}$ is represented by $Z \triangleq \lambda x_1. 0$; but zero$^1 \circ u$ is not represented by $\lambda x_1. Z(U x_1)$, because $(\text{zero}^1 \circ u)(n) \uparrow$ whereas $(\lambda x_1. Z(U x_1))(n) = \beta Z \Omega = \beta 0$. (What is zero$^1 \circ u$ represented by?)
**Primitive recursion**

**Theorem.** Given $f \in \mathbb{N}^n \rightarrow \mathbb{N}$ and $g \in \mathbb{N}^{n+2} \rightarrow \mathbb{N}$, there is a unique $h \in \mathbb{N}^{n+1} \rightarrow \mathbb{N}$ satisfying

$$
\begin{align*}
    h(\bar{x}, 0) & \equiv f(\bar{x}) \\
    h(\bar{x}, x + 1) & \equiv g(\bar{x}, x, h(\bar{x}, x))
\end{align*}
$$

for all $\bar{x} \in \mathbb{N}^n$ and $x \in \mathbb{N}$.

We write $\rho^n(f, g)$ for $h$ and call it the partial function defined by primitive recursion from $f$ and $g$.

---

**Representing primitive recursion**

If $f \in \mathbb{N}^n \rightarrow \mathbb{N}$ is represented by a $\lambda$-term $F$ and $g \in \mathbb{N}^{n+2} \rightarrow \mathbb{N}$ is represented by a $\lambda$-term $G$, we want to show $\lambda$-definability of the unique $h \in \mathbb{N}^{n+1} \rightarrow \mathbb{N}$ satisfying

$$
\begin{align*}
    h(\bar{a}, 0) & = f(\bar{a}) \\
    h(\bar{a}, a + 1) & = g(\bar{a}, a, h(\bar{a}, a))
\end{align*}
$$
Representing primitive recursion

If \( f \in \mathbb{N}^n \rightarrow \mathbb{N} \) is represented by a \( \lambda \)-term \( F \) and \( g \in \mathbb{N}^{n+2} \rightarrow \mathbb{N} \) is represented by a \( \lambda \)-term \( G \), we want to show \( \lambda \)-definability of the unique \( h \in \mathbb{N}^{n+1} \rightarrow \mathbb{N} \) satisfying \( h = \Phi_{f,g}(h) \)

where \( \Phi_{f,g} \in (\mathbb{N}^{n+1} \rightarrow \mathbb{N}) \rightarrow (\mathbb{N}^{n+1} \rightarrow \mathbb{N}) \) is given by

\[
\Phi_{f,g}(h)(\vec{a}, a) \triangleq \text{if } a = 0 \text{ then } f(\vec{a}) \quad \text{else } g(\vec{a}, a - 1, h(\vec{a}, a - 1))
\]

Strategy:
- show that \( \Phi_{f,g} \) is \( \lambda \)-definable;
- show that we can solve fixed point equations \( X = M X \) up to \( \beta \)-conversion in the \( \lambda \)-calculus.
Representing booleans

\[
\begin{align*}
\text{True} & \triangleq \lambda x y. x \\
\text{False} & \triangleq \lambda x y. y \\
\text{If} & \triangleq \lambda f x y. f x y
\end{align*}
\]

satisfy

- If True \(M N \equiv_\beta \text{True}\) \(M N \equiv_\beta M\)
- If False \(M N \equiv_\beta \text{False}\) \(M N \equiv_\beta N\)

Representing test-for-zero

\[
\text{Eq}_0 \triangleq \lambda x. x(\lambda y. \text{False}) \text{True}
\]

satisfies

- \(\text{Eq}_0 0 \equiv_\beta 0 (\lambda y. \text{False}) \text{True} \equiv_\beta \text{True}\)
- \(\text{Eq}_0 n + 1 \equiv_\beta n + 1 (\lambda y. \text{False}) \text{True} \equiv_\beta (\lambda y. \text{False})^{n+1} \text{True} \equiv_\beta (\lambda y. \text{False})((\lambda y. \text{False})^n \text{True}) \equiv_\beta \text{False}\)
Representing ordered pairs

\[
\text{Pair} \triangleq \lambda xy f. f xy \\
\text{Fst} \triangleq \lambda f. f \text{True} \\
\text{Snd} \triangleq \lambda f. f \text{False}
\]

satisfy

\[
\begin{align*}
\text{Fst}(\text{Pair} MN) & = \beta \text{ Fst}(\lambda f. f MN) \\
& = \beta (\lambda f. f MN) \text{ True} \\
& = \beta \text{ True } MN \\
& = \beta M
\end{align*}
\]

\[
\begin{align*}
\text{Snd}(\text{Pair} MN) & = \beta \cdots = \beta N
\end{align*}
\]

Representing predecessor

Want \( \lambda \)-term \( \text{Pred} \) satisfying

\[
\begin{align*}
\text{Pred } n + 1 & = \beta n \\
\text{Pred } 0 & = \beta 0
\end{align*}
\]

Have to show how to reduce the “\( n + 1 \)-iterator” \( n + 1 \) to the “\( n \)-iterator” \( n \).

**Idea:** given \( f \), iterating the function \( g_f : (x, y) \mapsto (f(x), x) \) \( n + 1 \) times starting from \( (x, x) \) gives the pair \( (f^{n+1}(x), f^n(x)) \). So we can get \( f^n(x) \) from \( f^{n+1}(x) \) parametrically in \( f \) and \( x \), by building \( g_f \) from \( f \), iterating \( n + 1 \) times from \( (x, x) \) and then taking the second component.

Hence...
Representing predecessor

Want $\lambda$-term $\text{Pred}$ satisfying

\[
\begin{align*}
\text{Pred}_n + 1 &= \beta n \\
\text{Pred}_0 &= \beta 0
\end{align*}
\]

where

\[
\text{Pred} \triangleq \lambda y f x. \text{Snd}(y (G f) (\text{Pair} x x))
\]

\[
G \triangleq \lambda f p. \text{Pair}(f (\text{Fst} p))(\text{Fst} p)
\]

has the required $\beta$-reduction properties. [Exercise]

---

Curry’s fixed point combinator $\text{Y}$

\[
\text{Y} \triangleq \lambda f. (\lambda x. f(x x))(\lambda x. f(x x))
\]

satisfies $\text{Y} M \rightarrow (\lambda x. M(x x))(\lambda x. M(x x))$

\[
\rightarrow M((\lambda x. M(x x))(\lambda x. M(x x)))
\]

hence $\text{Y} M \rightarrow M((\lambda x. M(x x))(\lambda x. M(x x))) \leftrightarrow M(\text{Y} M)$.

So for all $\lambda$-terms $M$ we have

\[
\text{Y} M = \beta M(\text{Y} M)
\]
Representing primitive recursion

If \( f \in \mathbb{N}^n \rightarrow \mathbb{N} \) is represented by a \( \lambda \)-term \( F \) and \( g \in \mathbb{N}^{n+2} \rightarrow \mathbb{N} \) is represented by a \( \lambda \)-term \( G \), we want to show \( \lambda \)-definability of the unique \( h \in \mathbb{N}^{n+1} \rightarrow \mathbb{N} \) satisfying \( h = \Phi_{f,g}(h) \)

where \( \Phi_{f,g} \in (\mathbb{N}^{n+1} \rightarrow \mathbb{N}) \rightarrow (\mathbb{N}^{n+1} \rightarrow \mathbb{N}) \) is given by

\[
\Phi_{f,g}(h)(\bar{a}, a) \triangleq \begin{cases} 
 f(\bar{a}) & \text{if } a = 0 \\
 g(\bar{a}, a - 1, h(\bar{a}, a - 1)) & \text{else}
\end{cases}
\]

We now know that \( h \) can be represented by

\[
\Upsilon(\lambda z \bar{x}. \text{If } (\text{Eq}_0 x)(F \bar{x})(G \bar{x} (\text{Pred} x)(z \bar{x} (\text{Pred} x))))).
\]

Representing primitive recursion

Recall that the class \textbf{PRIM} of primitive recursive functions is the smallest collection of (total) functions containing the basic functions and closed under the operations of composition and primitive recursion.

Combining the results about \( \lambda \)-definability so far, we have: \textbf{every } \( f \in \textbf{PRIM} \textbf{ is } \lambda \text{-definable}. \)

So for \( \lambda \)-definability of all recursive functions, we just have to consider how to represent minimization. Recall...
Minimization

Given a partial function \( f \in \mathbb{N}^{n+1} \rightarrow \mathbb{N} \), define \( \mu^n f \in \mathbb{N}^n \rightarrow \mathbb{N} \) by

\[
\mu^n f(\vec{x}) \triangleq \text{least } x \text{ such that } f(\vec{x}, x) = 0 \\
\text{and for each } i = 0, \ldots, x - 1, \\
f(\vec{x}, i) \text{ is defined and } > 0 \\
(\text{undefined if there is no such } x)
\]

Can express \( \mu^n f \) in terms of a fixed point equation:

\[
\mu^n f(\vec{x}) \equiv g(\vec{x}, 0) \text{ where } g \text{ satisfies } g = \Psi_f(g)
\]

with \( \Psi_f \in (\mathbb{N}^{n+1} \rightarrow \mathbb{N}) \rightarrow (\mathbb{N}^{n+1} \rightarrow \mathbb{N}) \) defined by

\[
\Psi_f(g)(\vec{x}, x) \equiv \text{if } f(\vec{x}, x) = 0 \text{ then } x \text{ else } g(\vec{x}, x + 1)
\]

Representing minimization

Suppose \( f \in \mathbb{N}^{n+1} \rightarrow \mathbb{N} \) (totally defined function) satisfies \( \forall \vec{a} \exists a \ (f(\vec{a}, a) = 0) \), so that \( \mu^n f \in \mathbb{N}^n \rightarrow \mathbb{N} \) is totally defined.

Thus for all \( \vec{a} \in \mathbb{N}^n \), \( \mu^n f(\vec{a}) = g(\vec{a}, 0) \) with \( g = \Psi_f(g) \) and \( \Psi_f(g)(\vec{a}, a) \) given by

\[
\text{if } (f(\vec{a}, a) = 0) \text{ then } a \text{ else } g(\vec{a}, a + 1).
\]

So if \( f \) is represented by a \( \lambda \)-term \( F \), then \( \mu^n f \) is represented by

\[
\lambda \vec{x}. \Psi (\lambda z \vec{x} x. \text{if } (\text{Eq}_0(F \vec{x} x)) x (z \vec{x} (\text{Succ } x))) \vec{x} 0
\]
Recursive implies $\lambda$-definable

**Fact:** every partial recursive $f \in \mathbb{N}^n \to \mathbb{N}$ can be expressed in a standard form as $f = g \circ (\mu^n h)$ for some $g, h \in \text{PRIM}$. (Follows from the proof that computable = partial-recursive.)

Hence every (total) recursive function is $\lambda$-definable.

More generally, every partial recursive function is $\lambda$-definable, but matching up $\uparrow$ with $\not\exists \beta -nf$ makes the representations more complicated than for total functions: see [Hindley, J.R. & Seldin, J.P. (CUP, 2008), chapter 4.]

---

Computable = $\lambda$-definable

**Theorem.** A partial function is computable if and only if it is $\lambda$-definable.

We already know that computable = partial recursive $\Rightarrow$ $\lambda$-definable. So it just remains to see that $\lambda$-definable functions are RM computable. To show this one can

- code $\lambda$-terms as numbers (ensuring that operations for constructing and deconstructing terms are given by RM computable functions on codes)
- write a RM interpreter for (normal order) $\beta$-reduction.

The details are straightforward, if tedious.
