## Hamiltonian Graphs

Recall the definition of **HAM**—the language of Hamiltonian graphs.

Given a graph  $G = (V, E)$ , a *Hamiltonian cycle* in  $G$  is a path in the graph, starting and ending at the same node, such that every node in  $V$  appears on the cycle *exactly once*.

A graph is called *Hamiltonian* if it contains a Hamiltonian cycle.

The language **HAM** is the set of encodings of Hamiltonian graphs.

## Hamiltonian Cycle

We can construct a reduction from **3SAT** to **HAM**

Essentially, this involves coding up a Boolean expression as a graph, so that every satisfying truth assignment to the expression corresponds to a Hamiltonian circuit of the graph.

This reduction is much more intricate than the one for **IND**.

## Travelling Salesman

Recall the travelling salesman problem

Given

- $V$  — a set of nodes.
- $c : V \times V \rightarrow \mathbb{N}$  — a cost matrix.

Find an ordering  $v_1, \dots, v_n$  of  $V$  for which the total cost:

$$c(v_n, v_1) + \sum_{i=1}^{n-1} c(v_i, v_{i+1})$$

is the smallest possible.

## Travelling Salesman

As with other optimisation problems, we can make a decision problem version of the Travelling Salesman problem.

The problem **TSP** consists of the set of triples

$$(V, c : V \times V \rightarrow \mathbb{N}, t)$$

such that there is a tour of the set of vertices  $V$ , which under the cost matrix  $c$ , has cost  $t$  or less.

## Reduction

There is a simple reduction from **HAM** to **TSP**, mapping a graph  $(V, E)$  to the triple  $(V, c : V \times V \rightarrow \mathbb{N}, n)$ , where

$$c(u, v) = \begin{cases} 1 & \text{if } (u, v) \in E \\ 2 & \text{otherwise} \end{cases}$$

and  $n$  is the size of  $V$ .

## Sets, Numbers and Scheduling

It is not just problems about formulas and graphs that turn out to be **NP**-complete.

Literally hundreds of naturally arising problems have been proved **NP**-complete, in areas involving network design, scheduling, optimisation, data storage and retrieval, artificial intelligence and many others.

Such problems arise naturally whenever we have to construct a solution within constraints, and the most effective way appears to be an exhaustive search of an exponential solution space.

We now examine three more **NP**-complete problems, whose significance lies in that they have been used to prove a large number of other problems **NP**-complete, through reductions.

## 3D Matching

The decision problem of **3D Matching** is defined as:

Given three disjoint sets  $X, Y$  and  $Z$ , and a set of triples  $M \subseteq X \times Y \times Z$ , does  $M$  contain a matching?

I.e. is there a subset  $M' \subseteq M$ , such that each element of  $X, Y$  and  $Z$  appears in exactly one triple of  $M'$ ?

We can show that **3DM** is **NP**-complete by a reduction from **3SAT**.

## Reduction

If a Boolean expression  $\phi$  in 3CNF has  $n$  variables, and  $m$  clauses, we construct for each variable  $v$  the following gadget.

In addition, for every clause  $c$ , we have two elements  $x_c$  and  $y_c$ .

If the literal  $v$  occurs in  $c$ , we include the triple

$$(x_c, y_c, z_{vc})$$

in  $M$ .

Similarly, if  $\neg v$  occurs in  $c$ , we include the triple

$$(x_c, y_c, \bar{z}_{vc})$$

in  $M$ .

Finally, we include extra dummy elements in  $X$  and  $Y$  to make the numbers match up.

## Exact Set Covering

Two other well known problems are proved NP-complete by immediate reduction from 3DM.

*Exact Cover by 3-Sets* is defined by:

Given a set  $U$  with  $3n$  elements, and a collection  $S = \{S_1, \dots, S_m\}$  of three-element subsets of  $U$ , is there a sub collection containing exactly  $n$  of these sets whose union is all of  $U$ ?

The reduction from 3DM simply takes  $U = X \cup Y \cup Z$ , and  $S$  to be the collection of three-element subsets resulting from  $M$ .

## Set Covering

More generally, we have the *Set Covering* problem:

Given a set  $U$ , a collection of  $S = \{S_1, \dots, S_m\}$  subsets of  $U$  and an integer budget  $B$ , is there a collection of  $B$  sets in  $S$  whose union is  $U$ ?

## Knapsack

**KNAPSACK** is a problem which generalises many natural scheduling and optimisation problems, and through reductions has been used to show many such problems **NP**-complete.

In the problem, we are given  $n$  items, each with a positive integer value  $v_i$  and weight  $w_i$ .

We are also given a maximum total weight  $W$ , and a minimum total value  $V$ .

Can we select a subset of the items whose total weight does not exceed  $W$ , and whose total value exceeds  $V$ ?

## Reduction

The proof that **KNAPSACK** is **NP**-complete is by a reduction from the problem of Exact Cover by 3-Sets.

Given a set  $U = \{1, \dots, 3n\}$  and a collection of 3-element subsets of  $U$ ,  $S = \{S_1, \dots, S_m\}$ .

We map this to an instance of **KNAPSACK** with  $m$  elements each corresponding to one of the  $S_i$ , and having weight and value

$$\sum_{j \in S_i} (m+1)^{j-1}$$

and set the target weight and value both to

$$\sum_{j=0}^{3n-1} (m+1)^j$$
