## Knapsack

**KNAPSACK** is a problem which generalises many natural scheduling and optimisation problems, and through reductions has been used to show many such problems **NP**-complete.

In the problem, we are given  $n$  items, each with a positive integer value  $v_i$  and weight  $w_i$ .

We are also given a maximum total weight  $W$ , and a minimum total value  $V$ .

Can we select a subset of the items whose total weight does not exceed  $W$ , and whose total value exceeds  $V$ ?

## Scheduling

Some examples of the kinds of scheduling tasks that have been proved **NP**-complete include:

### Timetable Design

Given a set  $H$  of *work periods*, a set  $W$  of *workers* each with an associated subset of  $H$  (available periods), a set  $T$  of *tasks* and an assignment  $r : W \times T \rightarrow \mathbb{N}$  of *required work*, is there a mapping  $f : W \times T \times H \rightarrow \{0, 1\}$  which completes all tasks?

## Scheduling

### Sequencing with Deadlines

Given a set  $T$  of *tasks* and for each task a *length*  $l \in \mathbb{N}$ , a release time  $r \in \mathbb{N}$  and a deadline  $d \in \mathbb{N}$ , is there a work schedule which completes each task between its release time and its deadline?

### Job Scheduling

Given a set  $T$  of *tasks*, a number  $m \in \mathbb{N}$  of processors a length  $l \in \mathbb{N}$  for each task, and an overall deadline  $D \in \mathbb{N}$ , is there a multi-processor schedule which completes all tasks by the deadline?

## Responses to NP-Completeness

*Confronted by an NP-complete problem, say constructing a timetable, what can one do?*

- It's a single instance, does asymptotic complexity matter?
- What's the critical size? Is scalability important?
- Are there guaranteed restrictions on the input? Will a special purpose algorithm suffice?
- Will an approximate solution suffice? Are performance guarantees required?
- Are there useful heuristics that can constrain a search? Ways of ordering choices to control backtracking?

## Validity

We define **VAL**—the set of *valid* Boolean expressions—to be those Boolean expressions for which every assignment of truth values to variables yields an expression equivalent to **true**.

$$\phi \in \text{VAL} \Leftrightarrow \neg\phi \notin \text{SAT}$$

By an exhaustive search algorithm similar to the one for **SAT**, **VAL** is in  $\text{TIME}(n^{2^n})$ .

Is **VAL**  $\in$  **NP**?

## Validity

$\overline{\text{VAL}} = \{\phi \mid \phi \notin \text{VAL}\}$ —the *complement* of **VAL** is in **NP**.

Guess a *falsifying* truth assignment and verify it.

Such an algorithm does not work for **VAL**.

In this case, we have to determine whether *every* truth assignment results in **true**—a requirement that does not sit as well with the definition of acceptance by a nondeterministic machine.

## Complementation

If we interchange accepting and rejecting states in a deterministic machine that accepts the language **L**, we get one that accepts  $\overline{\text{L}}$ .

If a language  $\text{L} \in \text{P}$ , then also  $\overline{\text{L}} \in \text{P}$ .

Complexity classes defined in terms of nondeterministic machine models are not necessarily closed under complementation of languages.

Define,

**co-NP** – the languages whose complements are in **NP**.

## Succinct Certificates

The complexity class **NP** can be characterised as the collection of languages of the form:

$$L = \{x \mid \exists y R(x, y)\}$$

Where  $R$  is a relation on strings satisfying two key conditions

1.  $R$  is decidable in polynomial time.
2.  $R$  is *polynomially balanced*. That is, there is a polynomial  $p$  such that if  $R(x, y)$  and the length of  $x$  is  $n$ , then the length of  $y$  is no more than  $p(n)$ .

## Succinct Certificates

$y$  is a *certificate* for the membership of  $x$  in  $L$ .

**Example:** If  $L$  is **SAT**, then for a satisfiable expression  $x$ , a certificate would be a satisfying truth assignment.

## co-NP

As **co-NP** is the collection of complements of languages in **NP**, and **P** is closed under complementation, **co-NP** can also be characterised as the collection of languages of the form:

$$L = \{x \mid \forall y |y| < p(|x|) \rightarrow R'(x, y)\}$$

**NP** – the collection of languages with succinct certificates of membership.

**co-NP** – the collection of languages with succinct certificates of disqualification.

Any of the situations is consistent with our present state of knowledge:

- $P = NP = \text{co-NP}$
- $P = NP \cap \text{co-NP} \neq NP \neq \text{co-NP}$
- $P \neq NP \cap \text{co-NP} = NP = \text{co-NP}$
- $P \neq NP \cap \text{co-NP} \neq NP \neq \text{co-NP}$

## co-NP-complete

**VAL** – the collection of Boolean expressions that are *valid* is *co-NP-complete*.

Any language  $L$  that is the complement of an NP-complete language is *co-NP-complete*.

Any reduction of a language  $L_1$  to  $L_2$  is also a reduction of  $\bar{L}_1$ –the complement of  $L_1$ –to  $\bar{L}_2$ –the complement of  $L_2$ .

There is an easy reduction from the complement of **SAT** to **VAL**, namely the map that takes an expression to its negation.

$$\text{VAL} \in \text{P} \Rightarrow \text{P} = \text{NP} = \text{co-NP}$$

$$\text{VAL} \in \text{NP} \Rightarrow \text{NP} = \text{co-NP}$$

## Prime Numbers

Consider the decision problem **PRIME**:

Given a number  $x$ , is it prime?

This problem is in **co-NP**.

$$\forall y (y < x \rightarrow (y = 1 \vee \neg(\text{div}(y, x))))$$

Note again, the algorithm that checks for all numbers up to  $\sqrt{n}$  whether any of them divides  $n$ , is not polynomial, as  $\sqrt{n}$  is not polynomial in the size of the input string, which is  $\log n$ .

## Primality

Another way of putting this is that **Composite** is in **NP**.

Pratt (1976) showed that **PRIME** is in **NP**, by exhibiting succinct certificates of primality based on:

A number  $p > 2$  is *prime* if, and only if, there is a number  $r$ ,  $1 < r < p$ , such that  $r^{p-1} = 1 \pmod p$  and  $r^{\frac{p-1}{q}} \neq 1 \pmod p$  for all *prime divisors*  $q$  of  $p-1$ .
