Responses to NP-Completeness

Confronted by an NP-complete problem, say constructing a timetable, what can one do?

- It's a single instance, does asymptotic complexity matter?
- What's the critical size? Is scalability important?
- Are there guaranteed restrictions on the input? Will a special purpose algorithm suffice?
- Will an approximate solution suffice? Are performance guarantees required?
- Are there useful heuristics that can constrain a search? Ways of ordering choices to control backtracking?

We define VAL—the set of *valid* Boolean expressions—to be those Boolean expressions for which every assignment of truth values to variables yields an expression equivalent to **true**.

 $\phi \in \mathsf{VAL} \quad \Leftrightarrow \quad \neg \phi \not\in \mathsf{SAT}$

By an exhaustive search algorithm similar to the one for SAT, VAL is in $\mathsf{TIME}(n^2 2^n)$.

Is $VAL \in NP$?

Anuj Dawar

 $\overline{\mathsf{VAL}} = \{ \phi \mid \phi \notin \mathsf{VAL} \}$ —the *complement* of VAL is in NP.

Guess a *falsifying* truth assignment and verify it.

Such an algorithm does not work for VAL.

In this case, we have to determine whether *every* truth assignment results in **true**—a requirement that does not sit as well with the definition of acceptance by a nondeterministic machine.

Complementation

If we interchange accepting and rejecting states in a deterministic machine that accepts the language L, we get one that accepts \overline{L} .

If a language $L \in \mathsf{P}$, then also $\overline{L} \in \mathsf{P}$.

Complexity classes defined in terms of nondeterministic machine models are not necessarily closed under complementation of languages.

Define,

co-NP – the languages whose complements are in NP.

Succinct Certificates

The complexity class NP can be characterised as the collection of languages of the form:

 $L = \{x \mid \exists y R(x, y)\}$

Where R is a relation on strings satisfying two key conditions

- 1. R is decidable in polynomial time.
- 2. *R* is *polynomially balanced*. That is, there is a polynomial p such that if R(x, y) and the length of x is n, then the length of y is no more than p(n).

Succinct Certificates

y is a *certificate* for the membership of x in L.

Example: If L is SAT, then for a satisfiable expression x, a certificate would be a satisfying truth assignment.

As co-NP is the collection of complements of languages in NP, and P is closed under complementation, co-NP can also be characterised as the collection of languages of the form:

 $L = \{ x \mid \forall y \mid y \mid < p(|x|) \to R'(x, y) \}$

 $\mathsf{NP}-\mathsf{the}$ collection of languages with succinct certificates of membership.

co-NP – the collection of languages with succinct certificates of disqualification.

Any of the situations is consistent with our present state of knowledge:

- P = NP = co-NP
- $P = NP \cap co-NP \neq NP \neq co-NP$
- $P \neq NP \cap co-NP = NP = co-NP$
- $P \neq NP \cap co-NP \neq NP \neq co-NP$

co-NP-complete

VAL – the collection of Boolean expressions that are *valid* is *co-NP-complete*.

Any language L that is the complement of an NP-complete language is co-NP-complete.

Any reduction of a language L_1 to L_2 is also a reduction of $\overline{L_1}$ -the complement of L_1 -to $\overline{L_2}$ -the complement of L_2 .

There is an easy reduction from the complement of SAT to VAL, namely the map that takes an expression to its negation.

 $VAL \in P \Rightarrow P = NP = co-NP$

 $VAL \in NP \Rightarrow NP = co-NP$

Prime Numbers

Consider the decision problem **PRIME**:

Given a number x, is it prime?

This problem is in **co-NP**.

 $\forall y(y < x \rightarrow (y = 1 \lor \neg(\operatorname{div}(y, x))))$

Note again, the algorithm that checks for all numbers up to \sqrt{n} whether any of them divides n, is not polynomial, as \sqrt{n} is not polynomial in the size of the input string, which is $\log n$.

Primality

Another way of putting this is that Composite is in NP.

Pratt (1976) showed that PRIME is in NP, by exhibiting succinct certificates of primality based on:

A number p > 2 is *prime* if, and only if, there is a number r, 1 < r < p, such that $r^{p-1} = 1 \mod p$ and $r^{\frac{p-1}{q}} \neq 1 \mod p$ for all *prime divisors* q of p-1.

Primality

In 2002, Agrawal, Kayal and Saxena showed that **PRIME** is in **P**.

If a is co-prime to p,

$$(x-a)^p \equiv (x^p-a) \pmod{p}$$

if, and only if, p is a prime.

Checking this equivalence would take to long. Instead, the equivalence is checked *modulo* a polynomial $x^r - 1$, for "suitable" r.

The existence of suitable small r relies on deep results in number theory.
