Today: the matcher

- 1 Recap
- 2 Why ranked retrieval?
- 3 Term frequency
- 4 Zipf's Law and tf-idf weighting
- 5 The vector space model

- 1 Recap
- 2 Why ranked retrieval?
- 3 Term frequency
- 4 Zipf's Law and tf-idf weighting
- 5 The vector space model

- What to do when there is no exact match between query term and document term?
- Dictionary as hash, B-tree, trie
- **Wildcards** via permuterm
- and k-gram index
- k-gram index and edit-distance for **spelling correction**

- **Ranking** search results: why it is important (as opposed to just presenting a set of unordered Boolean results)
- **Term frequency**: This is a key ingredient for ranking.
- **Tf-idf ranking**: best known traditional ranking scheme
- And one explanation for why it works: **Zipf's Law**
- **Vector space model**: One of the most important formal models for information retrieval (along with Boolean and probabilistic models)

- 1 Recap
- 2 Why ranked retrieval?**
- 3 Term frequency
- 4 Zipf's Law and tf-idf weighting
- 5 The vector space model

- Thus far, our queries have been **Boolean**.
  - Documents either match or don't.
- **Good for expert users** with precise understanding of their needs and of the collection.
- Also **good for applications**: Applications can easily consume 1000s of results.
- **Not good for the majority of users**
- Don't want to write Boolean queries or wade through 1000s of results.
- This is particularly true of web search.

# Problem with Boolean search: Feast or famine

- Boolean queries often have either too few or too many results.

## Query 1

standard AND user AND dlink AND 650

→ 200,000 hits **Feast!**

## Query 2

standard AND user AND dlink AND 650  
AND no AND card AND found

→ 0 hits **Famine!**

- In Boolean retrieval, it takes a lot of skill to come up with a query that produces a manageable number of hits.
- In ranked retrieval, “feast or famine” is less of a problem.
- Condition: **Results that are more relevant are ranked higher than results that are less relevant.** (i.e., the ranking algorithm works.)

# Scoring as the basis of ranked retrieval

- Rank documents in the collection according to how relevant they are to a query
- Assign a score to each query-document pair, say in  $[0, 1]$ .
- This score measures how well document and query “match”.
- If the query consists of just one term . . .

lioness

- Score should be 0 if the query term does not occur in the document.
- The more frequent the query term in the document, the higher the score
- We will look at a number of alternatives for doing this.

# Take 1: Jaccard coefficient

- A commonly used measure of overlap of two sets
- Let  $A$  and  $B$  be two sets
- Jaccard coefficient:

$$\text{JACCARD}(A, B) = \frac{|A \cap B|}{|A \cup B|}$$

( $A \neq \emptyset$  or  $B \neq \emptyset$ )

- $\text{JACCARD}(A, A) = 1$
- $\text{JACCARD}(A, B) = 0$  if  $A \cap B = \emptyset$
- $A$  and  $B$  don't have to be the same size.
- Always assigns a number between 0 and 1.

# Jaccard coefficient: Example

- What is the query-document match score that the Jaccard coefficient computes for:

Query

“ides of March”

Document

“Caesar died in March”

- $JACCARD(q, d) = 1/6$

# What's wrong with Jaccard?

- It doesn't consider **term frequency** (how many occurrences a term has).
- It also does not consider that some terms are inherently more informative than frequent terms.
- We need a more sophisticated way of **normalizing** for the length of a document.
  - Later in this lecture, we'll use  $|A \cap B| / \sqrt{|A \cup B|}$  (cosine) ...
  - ... instead of  $|A \cap B| / |A \cup B|$  (Jaccard) for length normalization.

- 1 Recap
- 2 Why ranked retrieval?
- 3 Term frequency**
- 4 Zipf's Law and tf-idf weighting
- 5 The vector space model

# Binary incidence matrix

	Anthony and Cleopatra	Julius Caesar	The Tempest	Hamlet	Othello	Macbeth	...
ANTHONY	1	1	0	0	0	1	
BRUTUS	1	1	0	1	0	0	
CAESAR	1	1	0	1	1	1	
CALPURNIA	0	1	0	0	0	0	
CLEOPATRA	1	0	0	0	0	0	
MERCY	1	0	1	1	1	1	
WORSER	1	0	1	1	1	0	
...							

Each document is represented as a **binary vector**  $\in \{0, 1\}^{|V|}$ .

# Count matrix

	Anthony and Cleopatra	Julius Caesar	The Tempest	Hamlet	Othello	Macbeth	...
ANTHONY	157	73	0	0	0	1	
BRUTUS	4	157	0	2	0	0	
CAESAR	232	227	0	2	1	0	
CALPURNIA	0	10	0	0	0	0	
CLEOPATRA	57	0	0	0	0	0	
MERCY	2	0	3	8	5	8	
WORSER	2	0	1	1	1	5	
...							

Each document is now represented as a **count vector**  $\in \mathbb{N}^{|V|}$ .

# Bag of words model

- We do not consider the **order** of words in a document.
- Represented the same way:

John is quicker than Mary  
Mary is quicker than John

- This is called a **bag of words model**.
- In a sense, this is a step back: The positional index was able to distinguish these two documents.

- The term frequency  $tf_{t,d}$  of term  $t$  in document  $d$  is defined as the number of times that  $t$  occurs in  $d$ .
- We could just use  $tf$  as is (“raw term frequency”).
- A document with  $tf = 10$  occurrences of the term is more relevant than a document with  $tf = 1$  occurrence of the term.
- But not 10 times more relevant.
- Relevance does not increase proportionally with term frequency.

# Instead of raw frequency: Log frequency weighting

- The log frequency weight of term  $t$  in  $d$  is defined as follows

$$w_{t,d} = \begin{cases} 1 + \log_{10} \text{tf}_{t,d} & \text{if } \text{tf}_{t,d} > 0 \\ 0 & \text{otherwise} \end{cases}$$

$\text{tf}_{t,d}$	0	1	2	10	1000
$w_{t,d}$	0	1	1.3	2	4

- Score for a document-query pair: sum over terms  $t$  in both  $q$  and  $d$ :

$$\text{tf-matching-score}(q, d) = \sum_{t \in q \cap d} (1 + \log \text{tf}_{t,d})$$

- The score is 0 if none of the query terms is present in the document.

# Overview

- 1 Recap
- 2 Why ranked retrieval?
- 3 Term frequency
- 4 Zipf's Law and tf-idf weighting**
- 5 The vector space model

# Frequency in document vs. frequency in collection

- In addition, to term frequency (the frequency of the term in the document) ...
- ...we also want to reward terms which are **rare** in the document collection overall.
- Now: excursion to an important statistical observation about language.

- How many frequent vs. infrequent terms should we expect in a collection?
- In natural language, there are **a few very frequent** terms and **very many very rare** terms.

## Zipf's law

The  $i^{\text{th}}$  most frequent term has frequency  $cf_i$  proportional to  $1/i$ :

$$cf_i \propto \frac{1}{i}$$

- $cf_i$  is collection frequency: the number of occurrences of the term  $t_i$  in the collection.

## Zipf's law

The  $i^{\text{th}}$  most frequent term has frequency  $cf_i$  proportional to  $1/i$ :

$$cf_i \propto \frac{1}{i}$$

- So if the most frequent term (*the*) occurs  $cf_1$  times, then the second most frequent term (*of*) has half as many occurrences  $cf_2 = \frac{1}{2}cf_1 \dots$
- ... and the third most frequent term (*and*) has a third as many occurrences  $cf_3 = \frac{1}{3}cf_1$  etc.
- Equivalent:  $cf_i = p \cdot i^k$  and  $\log cf_i = \log p + k \log i$  (for  $k = -1$ )
- Example of a power law

# Zipf's Law: Examples from 5 Languages

Top 10 most frequent words in some large language samples:

English		German		Spanish		Italian		Dutch	
1	the 61,847	1	der 7,377,879	1	que 32,894	1	non 25,757	1	de 4,770

# Zipf's law: Rank $\times$ Frequency $\sim$ Constant

English:	Rank $R$	Word	Frequency $f$	$R \times f$
	10	he	877	8770
	20	but	410	8200
	30	be	294	8820
	800	friends	10	8000
	1000	family	8	8000

German:	Rank $R$	Word	Frequency $f$	$R \times f$
	10	sich	1,680,106	16,801,060
	100	immer	197,502	19,750,200
	500	Mio	36,116	18,059,500
	1,000	Medien	19,041	19,041,000
	5,000	Miete	3,755	19,041,000
	10,000	vorläufige	1.664	16,640,000

## Other collections (allegedly) obeying power laws

- Sizes of settlements
- Frequency of access to web pages
- Income distributions amongst top earning 3% individuals
- Korean family names
- Size of earth quakes
- Word senses per word
- Notes in musical performances
- ...

# Zipf's law for Reuters

Fit is not great.

# Desired weight for rare terms

- Rare terms are more informative than frequent terms.
- Consider a term in the query that is **rare** in the collection (e.g., ARACHNOCENTRIC).
- A document containing this term is very likely to be relevant.
- → We want **high weights for rare terms** like ARACHNOCENTRIC.

# Desired weight for frequent terms

- Frequent terms are less informative than rare terms.
- Consider a term in the query that is **frequent** in the collection (e.g., GOOD, INCREASE, LINE).
- A document containing this term is more likely to be relevant than a document that doesn't ...
- ...but words like GOOD, INCREASE and LINE are not sure indicators of relevance.
- → **For frequent terms** like GOOD, INCREASE, and LINE, we want positive weights ...
- ...but **lower weights** than for rare terms.

- We want **high weights for rare terms** like ARACHNOCENTRIC.
- We want **low (positive) weights for frequent words** like GOOD, INCREASE, and LINE.
- We will use **document frequency** to factor this into computing the matching score.
- The document frequency is **the number of documents in the collection that the term occurs in.**

- $df_t$  is the document frequency, the number of documents that  $t$  occurs in.
- $df_t$  is an inverse measure of the **informativeness** of term  $t$ .
- We define the **idf weight** of term  $t$  as follows:

$$idf_t = \log_{10} \frac{N}{df_t}$$

( $N$  is the number of documents in the collection.)

- $idf_t$  is a measure of the **informativeness** of the term.
- $\log \frac{N}{df_t}$  instead of  $\frac{N}{df_t}$  to “dampen” the effect of idf
- Note that we use the log transformation for both term frequency and document frequency.

## Examples for idf

Compute  $\text{idf}_t$  using the formula:  $\text{idf}_t = \log_{10} \frac{1,000,000}{\text{df}_t}$

term	$\text{df}_t$	$\text{idf}_t$
calpurnia	1	6
animal	100	4
sunday	1000	3
fly	10,000	2
under	100,000	1
the	1,000,000	0

- idf affects the ranking of documents for **queries with at least two terms**.
- For example, in the query “arachnocentric line”, idf weighting **increases** the relative weight of ARACHNOCENTRIC and **decreases** the relative weight of LINE.
- idf has **little effect** on ranking for **one-term queries**.

# Collection frequency vs. Document frequency

Term	Collection frequency	Document frequency
INSURANCE	10440	3997
TRY	10422	8760

- Collection frequency of  $t$ : number of tokens of  $t$  in the collection
- Document frequency of  $t$ : number of documents  $t$  occurs in
- Clearly, `INSURANCE` is a more discriminating search term and should get a higher weight.
- This example suggests that `df` (and `idf`) is better for weighting than `cf` (and “`icf`”).

- The tf-idf weight of a term is the product of its tf weight and its idf weight.

tf-idf weight

$$w_{t,d} = (1 + \log \text{tf}_{t,d}) \cdot \log \frac{N}{\text{df}_t}$$

- tf-weight
- idf-weight
- Best known weighting scheme in information retrieval
- Alternative names: tf.idf, tf x idf

# Overview

MERCY	2	0	3	8	5	8	
WORSER	2	0	1	1	1	5	
...							

Each document is now represented as a **count vector**  $\in \mathbb{N}^{|V|}$ .

# Binary $\rightarrow$ count $\rightarrow$ weight matrix

	Anthony and Cleopatra	Julius Caesar	The Tempest	Hamlet	Othello	Macbeth	...
ANTHONY	5.25	3.18	0.0	0.0	0.0	0.35	
BRUTUS	1.21	6.10	0.0	1.0	0.0	0.0	
CAESAR	8.59	2.54	0.0	1.51	0.25	0.0	
CALPURNIA	0.0	1.54	0.0	0.0	0.0	0.0	
CLEOPATRA	2.85	0.0	0.0	0.0	0.0	0.0	
MERCY	1.51	0.0	1.90	0.12	5.25	0.88	
WORSER	1.37	0.0	0.11	4.15	0.25	1.95	
...							

Each document is now represented as a **real-valued vector** of tf-idf weights  $\in \mathbb{R}^{|V|}$ .

- Each document is now represented as a real-valued vector of tf-idf weights  $\in \mathbb{R}^{|V|}$ .
- So we have a  $|V|$ -dimensional real-valued vector space.
- Terms are **axes** of the space.
- Documents are **points** or **vectors** in this space.
- Very high-dimensional: tens of millions of dimensions when you apply this to web search engines
- Each vector is very sparse - most entries are zero.

- **Key idea 1:** do the same for **queries**: represent them as vectors in the high-dimensional space
- **Key idea 2:** Rank documents according to their **proximity** to the query
- proximity  $\approx$  negative distance
- This allows us to rank relevant documents higher than nonrelevant documents

# How do we formalize vector space similarity?

- First cut: (negative) distance between two points
- (= distance between the end points of the two vectors)
- Euclidean distance?
- Euclidean distance is a bad idea ...
- ... because Euclidean distance is **large** for vectors **of different lengths**.

# Why distance is a bad idea

The Euclidean distance of  $\vec{q}$  and  $\vec{d}_2$  is large although the distribution of terms in the query  $q$  and the distribution of terms in the document  $d_2$  are very similar.

# Use angle instead of distance

- Rank documents according to angle with query
- Thought experiment: take a document  $d$  and append it to itself. Call this document  $d'$ .  $d'$  is twice as long as  $d$ .
- “Semantically”  $d$  and  $d'$  have the same content.
- The angle between the two documents is 0, corresponding to maximal similarity ...
- ... even though the Euclidean distance between the two documents can be quite large.

- The following two notions are equivalent.
  - Rank documents according to the **angle** between query and document in decreasing order
  - Rank documents according to **cosine**(query,document) in increasing order
- Cosine is a monotonically decreasing function of the angle for the interval  $[0^\circ, 180^\circ]$

# Length normalization

- How do we compute the cosine?
- A vector can be (length-) normalized by dividing each of its components by its length – here we use the  $L_2$  norm:

$$\|x\|_2 = \sqrt{\sum_i x_i^2}$$

- This maps vectors onto the unit sphere ...
- ... since after normalization:  $\|x\|_2 = \sqrt{\sum_i x_i^2} = 1.0$
- As a result, longer documents and shorter documents have weights of the same order of magnitude.
- Effect on the two documents  $d$  and  $d'$  ( $d$  appended to itself) from earlier slide: they have **identical vectors** after length-normalization.

## Cosine similarity between query and document

$$\cos(\vec{q}, \vec{d}) = \text{SIM}(\vec{q}, \vec{d}) = \frac{\vec{q} \cdot \vec{d}}{|\vec{q}| |\vec{d}|} = \frac{\sum_{i=1}^{|\mathcal{V}|} q_i d_i}{\sqrt{\sum_{i=1}^{|\mathcal{V}|} q_i^2} \sqrt{\sum_{i=1}^{|\mathcal{V}|} d_i^2}}$$

- $q_i$  is the tf-idf weight of term  $i$  in the query.
- $d_i$  is the tf-idf weight of term  $i$  in the document.
- $|\vec{q}|$  and  $|\vec{d}|$  are the lengths of  $\vec{q}$  and  $\vec{d}$ .
- This is the **cosine similarity** of  $\vec{q}$  and  $\vec{d}$  . . . . . or, equivalently, the cosine of the angle between  $\vec{q}$  and  $\vec{d}$ .

- For normalized vectors, the cosine is equivalent to the dot product or scalar product.
- $\cos(\vec{q}, \vec{d}) = \vec{q} \cdot \vec{d} = \sum_i q_i \cdot d_i$ 
  - (if  $\vec{q}$  and  $\vec{d}$  are length-normalized).

# Cosine similarity illustrated

How similar are the following novels?

SaS: Sense and Sensibility

PaP: Pride and Prejudice

WH: Wuthering Heights

Term frequencies (raw counts)

term	SaS	PaP	WH
AFFECTION	115	58	20
JEALOUS	10	7	11
GOSSIP	2	0	6
WUTHERING	0	0	38

# Cosine: Example

term	Term frequencies (raw counts)			Log frequency weighting			Log frequency weighting and cosine normalisation		
	SaS	PaP	WH	SaS	PaP	WH	SaS	PaP	WH
AFFECTION	115	58	20	3.06	2.76	2.30	0.789	0.832	0.524
JEALOUS	10	7	11	2.0	1.85	2.04	0.515	0.555	0.465
GOSSIP	2	0	6	1.30	0.00	1.78	0.335	0.000	0.405
WUTHERING	0	0	38	0.00	0.00	2.58	0.000	0.000	0.588

- (To simplify this example, we don't do idf weighting.)
- $\cos(\text{SaS}, \text{PaP}) \approx 0.789 * 0.832 + 0.515 * 0.555 + 0.335 * 0.0 + 0.0 * 0.0 \approx 0.94$ .
- $\cos(\text{SaS}, \text{WH}) \approx 0.79$
- $\cos(\text{PaP}, \text{WH}) \approx 0.69$

# Components of tf-idf weighting

Term frequency		Document frequency		Normalization	
n (natural)	$tf_{t,d}$	n (no)	1	n (none)	1
l (logarithm)	$1 + \log(tf_{t,d})$	t (idf)	$\log \frac{N}{df_t}$	c (cosine)	$\frac{1}{\sqrt{w_1^2 + w_2^2 + \dots + w_M^2}}$
a (augmented)	$0.5 + \frac{0.5 \times tf_{t,d}}{\max_t(tf_{t,d})}$	p (prob idf)	$\max\{0, \log \frac{N - df_t}{df_t}\}$	u (pivoted unique)	$1/u$
b (boolean)	$\begin{cases} 1 & \text{if } tf_{t,d} > 0 \\ 0 & \text{otherwise} \end{cases}$			b (byte size)	$1/CharLength^\alpha$ , $\alpha < 1$
L (log ave)	$\frac{1 + \log(tf_{t,d})}{1 + \log(\text{ave}_{t \in d}(tf_{t,d}))}$				

Best known combination of weighting options

Default: no weighting

- We often use **different weightings** for queries and documents.
- 
- Notation: ddd.qqq

Example: **lnc.ltn**

Document:

**l**ogarithmic tf

**n**o df weighting

**c**osine normalization

Query:

**l**ogarithmic tf

**t** – means idf

**n**o normalization

# tf-idf example: Inc.ltn

Query: "best car insurance". Document: "car insurance auto insurance".

word	query					document				product
	tf-raw	tf-wght	df	idf	weight	tf-raw	tf-wght	weight	n'lized	
auto	0	0	5000	2.3	0	1	1	1	0.52	0
best	1	1	50000	1.3	1.3	0	0	0	0	0
car	1	1	10000	2.0	2.0	1	1	1	0.52	1.04
insurance	1	1	1000	3.0	3.0	2	1.3	1.3	0.68	2.04

Key to columns: **tf-raw**: raw (unweighted) term frequency, **tf-wght**: logarithmically weighted term frequency, **df**: document frequency, **idf**: inverse document frequency, **weight**: the final weight of the term in the query or document, **n'lized**: document weights after cosine normalization, **product**: the product of final query weight and final document weight

$$\sqrt{1^2 + 0^2 + 1^2 + 1.3^2} \approx 1.92$$

$$1/1.92 \approx 0.52$$

$$1.3/1.92 \approx 0.68$$

Final similarity score between query and document:  $\sum_i w_{qi} \cdot w_{di} = 0 + 0 + 1.04 + 2.04 = 3.08$

## Summary: Ranked retrieval in the vector space model

- Represent the query as a weighted tf-idf vector
- Represent each document as a weighted tf-idf vector
- Compute the cosine similarity between the query vector and each document vector
- Rank documents with respect to the query
- Return the top  $K$  (e.g.,  $K = 10$ ) to the user

- MRS, Chapter 5.1.2 (Zipf's Law)
- MRS, Chapter 6 (Term Weighting)
