

# Compositional distributional semantics

Ann Copestake

Computer Laboratory  
University of Cambridge

November 2017

# Outline

Background / recap

Distributional semantics for phrases

Distributional semantics for individuals

Functional distributional semantics

Slides marked (A) from Aurelie Herbelot, (G) from Guy Emerson

# Outline.

Background / recap

Distributional semantics for phrases

Distributional semantics for individuals

Functional distributional semantics

# Compositional semantics

- ▶ Compositional semantics is about providing a meaning representation for an entire sentence.
- ▶ Classically (e.g., Montague) based on syntax and morphology, meaning expressed as in logic:

$$\begin{array}{l} \textit{every white cat is asleep} \\ \forall x[[\textit{white}'(x) \wedge \textit{cat}'(x)] \rightarrow \textit{asleep}'(x)] \end{array}$$

- ▶ Structures built deterministically from a rich syntactic analysis (quantifier scope possibly underspecified).
- ▶ Useful in applications like database interfaces where predicates can be grounded.
- ▶ Also used for RTE etc with inference rules.
- ▶ Can be automatically induced for limited domains.

# Distributional semantics

- ▶ Classically, distributional semantics is about providing a meaning representation for words.
- ▶ But most approaches capture **relatedness** rather than genuine **similarity**: e.g., astronomer is related to telescope.
- ▶ Based on context in corpora, always automatically induced.
- ▶ Little or no morphology or syntax in most approaches.
- ▶ Used in lots of practical applications, starting with IR.
- ▶ Word embeddings used in neural models are a form of distributional semantics.

# Compositional distributional semantics

Various strands of work:

- ▶ Distributional semantics for phrases (most work is really about this).
  - ▶ doc2vec: not usually described as compositional distributional semantics but clearly related.
  - ▶ Non-compositionality: multiword expressions.
- ▶ Theoretical accounts that combine compositional semantics and distributional semantics (not so relevant for this course).
- ▶ Distributional semantics for individuals (Herbelot).
- ▶ Also 'Functional distributional semantics' (Emerson) and work by Erk, Boleda and others.

# Outline.

Background / recap

**Distributional semantics for phrases**

Distributional semantics for individuals

Functional distributional semantics

# Distributional semantics for phrases

- ▶ Problem specification?
  - ▶ Combine vectors to allow for sparse data: **metal spoon** vs **ebony tripod**
  - ▶ Capturing ordering effects: **man bites dog** vs **dog bites man**
  - ▶ Semantics for full sentences: quantifiers, truth?
- ▶ Methods: addition, multiplication, more complex functions. Higher-order tensors: e.g., transitive verbs are third order tensors.
- ▶ Evaluation
  - ▶ Predicting actual phrase distributions
  - ▶ Similarity judgements on phrasal test sets
  - ▶ Extrinsic evaluation

# Formal semantics of adjectives

- ▶ **white cat**:  $\text{white}'(x) \wedge \text{cat}'(x)$ : set intersection
- ▶ **tall tree**:  $\text{tall}'(x, \lambda y[P(y)]) \wedge \text{tree}'(x)$   
tall with respect to some contextually defined set of entities, tall with respect to trees, tall with respect to trees in Cambridge etc  
set intersection, but modified set (also gradable)
- ▶ **fake gun**:  $\text{fake}'(\text{gun}'(x))$   
may or may not be a gun (but note **fake watch**, **plastic aardvark**)

# Formal semantics and vector operations

- ▶ Denotation: **white cat**:  $\text{white}'(x) \wedge \text{cat}'(x)$ : set intersection. Intuitively corresponds to vector multiplication.
- ▶ Properties: a **white cat** has both the properties of being white and the properties of being a cat. Corresponds to vector addition.
- ▶ **white cat** vs \***cat white**  
**man bites dog** vs **dog bites man**  
So: order sensitive?  
BUT: order matters for English much more than some other languages  
how much syntax do we want to (re)do with tensor operations?

## Alternative models

- ▶ Ganesalingam and Herbelot, unpublished (2013)  
[www.cl.cam.ac.uk/~ah433/](http://www.cl.cam.ac.uk/~ah433/) for an overview of the mathematical properties
- ▶ Zanzotto et al (2015) also discuss different operations
- ▶ BUT: phrasal similarity datasets are too small to allow statistically valid distinctions between models

# Some results

- ▶ vector addition is usually a very difficult baseline to beat experimentally
- ▶ Grefenstette (2013) demonstrates impossibility of properly modelling quantifiers with the tensor models
- ▶ semantic deviance **spicy donkey**: Vecchi et al (2017)
- ▶ Also: **semi-compositionality** (compound nouns, *heavy table* vs *heavy rain* vs *heavy taxation* etc).

# Outline.

Background / recap

Distributional semantics for phrases

Distributional semantics for individuals

**Functional distributional semantics**

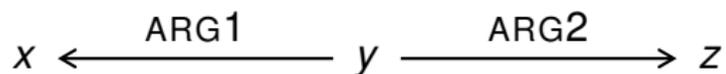

## Emerson and Copestake (2016, 2017)

- ▶ Functional Distributional Semantics: functions mapping from points in semantic space ('pixies' — corresponding to individuals) to truth values.
- ▶ Distinguish between probabilistic truth values and observed text.
- ▶ DMRS gives joint distribution between entities.
- ▶ Implementation using Cardinality Restricted Boltzmann machine (CaRBM) trained on the Wikiwoods corpus.
- ▶ Inference via conditional probabilities, also distributional similarity.
- ▶ e.g., *lion*, *stone lion*; *roses*, *plastic roses*, *stone roses*

# Functional Distributional Semantics (G)

dog ←<sup>ARG1</sup> chase →<sup>ARG2</sup> cat

# Functional Distributional Semantics (G)

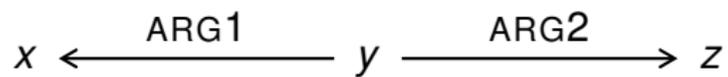

dog(x)

chase(y)

cat(z)

# Functional Distributional Semantics (G)

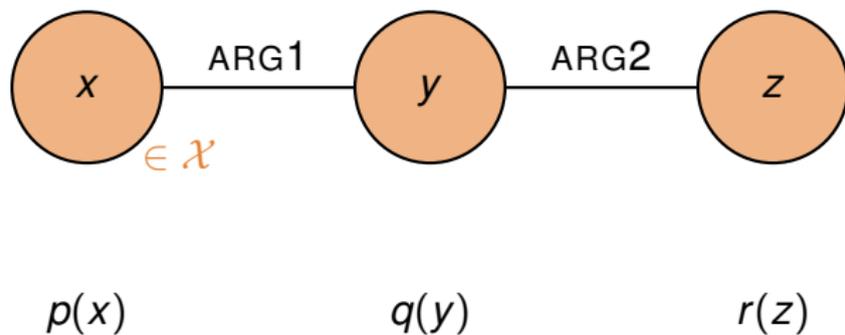

$p(x)$

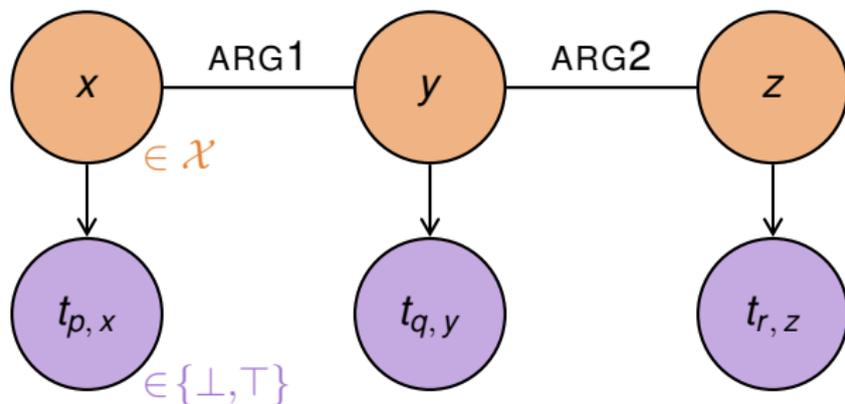

$q(y)$

$r(z)$

Designed to test compositionality — standard distributional model (relatedness) with addition works reasonably well.

But ...

## RELPRON confounders (G)

*balance*    *quality that ear maintains*  
*account*    *document that has balance*

Confounders fool simple similarity / vector addition.

## RELPRON confounders (G)

*balance*    *quality that ear maintains*  
*account*    *document that has **balance***

Confounders fool simple similarity / vector addition.

# RELPRON confounders (G)

- ▶ Test set has 27 confounders
- ▶ Word2Vec:
  - ▶ 17 confounders in top rank
  - ▶ all confounders in top 4 ranks

# RELPRON confounders (G)

- ▶ Test set has 27 confounders
- ▶ Word2Vec:
  - ▶ 17 confounders in top rank
  - ▶ all confounders in top 4 ranks
- ▶ Ensemble (word2vec plus FDS):
  - ▶ 9 confounders moved out of top 10 ranks

## Next time (last lecture)

November 16 15:00: Q and A

- ▶ How can neural models be used as a drop in for previous algorithms and how can the construction of a well-studied problem be modified for "the latest deep learning" to be useful?
- ▶ What is your approach to deep learning model selection?
- ▶ Evaluating model performance and learning in non-probabilistic models: can you do something equivalent to feature analysis in SVMs in neural models?
- ▶ What are your approaches to learning validation?

## Next time (last lecture)

November 16 15:00: Q and A

- ▶ How can neural models be used as a drop in for previous algorithms and how can the construction of a well-studied problem be modified for "the latest deep learning" to be useful?
- ▶ What is your approach to deep learning model selection?
- ▶ Evaluating model performance and learning in non-probabilistic models: can you do something equivalent to feature analysis in SVMs in neural models?
- ▶ What are your approaches to learning validation?

Vania and Lopez (2017): looks at whether various character-level LSTM models are really capturing morphology.
