6  Further Java (ACR)

(a) Describe the operation of `wait()` and `notifyAll()`. Ensure that your answer explains when locks are acquired and released.  [5 marks]

(b) A future is a mechanism to store the eventual result of a computation done in another thread. The idea is that the computation is run asynchronously and the calling thread only blocks if it tries to use a result that hasn’t been computed yet. An example program using a future is shown below.

```java
Future<String> f = new Future<String>() {
    @Override
    public String execute() {
        // ...long running computation...
        return data;
    }

    // ...

    String result = f.get(); // blocks if execute() unfinished
}
```

Use `wait()` and `notifyAll()` to provide an implementation of the `Future` class that would work with the example program above.  [10 marks]

(c) Give one potential advantage and one potential disadvantage of using `notify()` instead of `notifyAll()`.  [2 marks]

(d) Would it have been beneficial to use `notify()` instead of `notifyAll()` in your implementation? Justify your answer.  [3 marks]
