2002 Paper 12 Question 11

Computer Vision

The following very useful operator is often applied to an image I(x, y) in computer vision algorithms, to generate a related "image" g(x, y):

$$g(x,y) = \int_{\alpha} \int_{\beta} \nabla^2 e^{-((x-\alpha)^2 + (y-\beta)^2)/\sigma^2} I(\alpha,\beta) \ d\alpha \ d\beta$$

where

$$\nabla^2 = \left(\frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2}\right)$$

- (a) Give the general name for this type of mathematical operator, and the chief purpose that it serves in computer vision. [2 marks]
- (b) What image properties should correspond to the zeroes of the equation, i.e. those points (x, y) in the image I(x, y) where the above result g(x, y) = 0?

 [3 marks]
- (c) What is the significance of the parameter σ ? If you increased its value, would there be more or fewer points (x, y) at which g(x, y) = 0? [3 marks]
- (d) Describe the effect of the above operator in terms of the two-dimensional Fourier domain. What is the Fourier terminology for this image-domain operator? What are its general effects as a function of frequency, and as a function of orientation? [4 marks]
- (e) If the computation of g(x, y) above were to be implemented entirely by Fourier methods, would the complexity of this computation be greater or less than the image-domain operation expressed above, and why? What would be the trade-offs involved? [4 marks]
- (f) If the image I(x,y) has 2D Fourier Transform F(u,v), provide an expression for G(u,v), the 2D Fourier Transform of the desired result g(x,y) in terms of only the Fourier plane variables u,v,F(u,v), and the above parameter σ .
