

1 Artificial Intelligence (sbh11)

A neural network takes input vectors  $\mathbf{x} \in \mathbb{R}^n$ , has a single layer of hidden nodes  $h_i$  where  $i = 1, \dots, p$ , and a single output node  $o$ .

All nodes compute the function  $z = \sigma(a)$  where

$$a = \sum_{i=1}^m w_i z_i + w_0.$$

Here  $z$  and  $z_i$  denote the inputs and outputs of the node, and each node has its own set of weights  $w_0, w_1, \dots, w_m$ . Examples take the form  $(\mathbf{x}, y)$  and the error the network makes for an example is  $E(\mathbf{x}, y, \mathbf{w})$ , where  $\mathbf{w}$  is the collection of all the weights in the network.

(a) An example has been applied to the network and we know the quantity  $\delta = \partial E / \partial a$  for the output node  $o$ . Explain how this knowledge can be used to compute the partial derivative of  $E$  with respect to the weights for some hidden node  $h_i$ . [8 marks]

(b) The hidden nodes are now replaced with a different type of node, computing

$$z_i = h_i(\mathbf{x}) = \phi(\|\mathbf{x} - \mathbf{c}_i\|^2)$$

where  $\phi$  is some new function, the  $\mathbf{c}_i \in \mathbb{R}^n$  are the parameters for the new nodes, and

$$\|\mathbf{v}\|^2 = \mathbf{v}^T \mathbf{v}.$$

Give a detailed derivation of a training algorithm for this network. [12 marks]
