

1 Concepts in Programming Languages (am21)

```
(a) static void fastFilter(ArrayList<Datum> a, Predicate<String> p) {
    int j = 0;
    for (int i = 0; i < a.size(); i++) {
        if (p.test(a.get(i).key)) a.set(j++, a.get(i));
    }
    a.removeRange(j, a.size());
}
```

The above method `fastFilter` operating on `ArrayList<Datum>` was written by a Java programmer, perhaps misguided in the interests of speed. It uses method `removeRange` to remove the final `a.size()-j` elements from `a`. We wish to enable `fastFilter` also to operate on `ArrayList<DatumDash>` where `DatumDash` inherits from `Datum`.

- (i) Give code for a modified version using *subtype* polymorphism, justifying any changes and highlighting any unresolvable difficulties. [5 marks]
- (ii) Similarly, what changes, if any, would be required if the original `fastFilter` instead used Java classic `[]` arrays? Again justify your answer. [3 marks]
- (iii) Give a definition of `fastFilterInner` which uses *generic* polymorphism, along with a subtype-polymorphic wrapper whose signature matches that used in Part (a)(i). [*Hint*: consider moving the use of `.key`.] [4 marks]

```
(b) class Myst { // A Mystery?
    private Supplier<Int> act; // Java's name for void->Int
    private Myst(Supplier<Int> a) { act = a; }
    static Myst R(Int x) { return new Myst(()->x); }
    Myst B(Function<Int,Myst> f) { return f.apply(act.get()); }
    static Myst primIn = new Myst( () -> SystemIO.readInt() );
    static Myst primOut(Int x) {
        return new Myst(() -> { SystemIO.println(x); return x; } );
    }
    static void exec(Myst x) { x.act.get(); }
}
```

The class `Myst` is coded in a language resembling Java. What concept does it model and what does the code below conceptually do if executed in its scope?

```
Myst one = primIn.B(x -> primOut(x+1));
Myst two = R(2).B(y -> primIn.B(x -> primOut(x+y)));
Myst three = one.B(x -> two).B(x -> one);
exec(three);
```
