5 Programming in C and C++ (djg11)

(a) A FIFO is implemented in C using a singly-linked list that maintains global head and tail pointers. These are initialised to represent the empty FIFO as follows:

```
struct fifo_entry *head_ptr = 0;
struct fifo_entry **tail_ptr = &head_ptr;
```

The entries in the FIFO use a union to store either an integer or a double-precision floating point number. A further field records which is stored. Give syntactically-accurate C code that defines fifo_entry and either a function enqueue_int or a function enqueue_double enqueuing a new value into the FIFO.

[5 marks]

- (b) To avoid repetitive reallocation of memory, suppose now that FIFO entries that are no longer in use are to be saved in an auxiliary linked list. Give syntactically-accurate code that implements this approach and then discuss two other approaches for store management. [5 marks]
- (c) The C code in part (a) suffers from a lack of encapsulation variables like head_ptr are visible to the the rest of the program. Write C++ defining a class FIFO which maintains a single FIFO implemented using elements fifo_entry as defined in your answer above, but which only exports member functions enqueue_int, enqueue_double, isempty and

```
void dequeue(void do_I(int), void do_D(double));
```

It should not be possible to create an instance of class FIFO and storage allocation/deallocation should use C++ mechanisms rather than those of C. Your C++ is not required to be syntactically accurate, but should capture the main concepts. It is not necessary to give full code for the above four member functions – focusing on allocation and deallocation of fifo_entry elements suffices. [Note: do_I and do_D are user-provided processing functions to be applied to the dequeued value.] [6 marks]

(d) The following lines approximate (e.g. omitting access qualifiers) analogous generic/templated class definitions in Java and C++. Explain which types X are valid for use in Gen< X> and Tem< X>.

```
[Java]: class Gen<T> { T v; Gen() { v = 1; } }; [C++]: template<typename T> class Tem { T v; Tem() { v = 1; } }; [4 marks]
```
