

# Forwarding in a content based Network

Carzaniga and Wolf

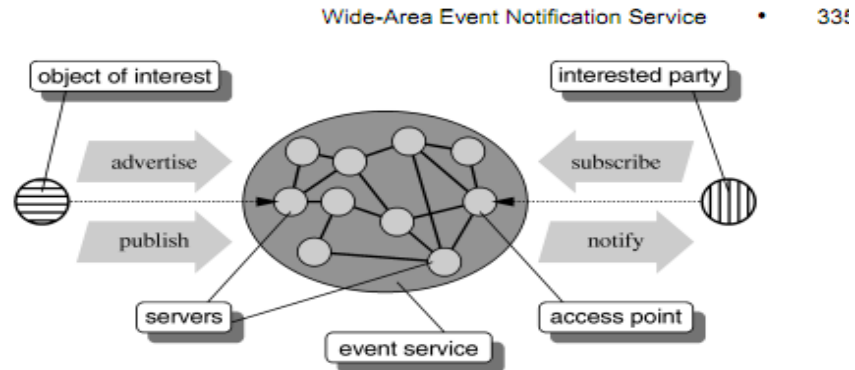

# Introduction

- Content based communication
  - Instead of explicit address
- Receiver/Subscriber use selection predicate to express what they are interested in
- Sender/Publisher just push data into the network
- Model
  - attribute/value pair
  - Selection predicate logical disjunction of conjunction [alert-type="intrusion"  $\wedge$  severity>2  $\vee$  class="alert"  $\wedge$  device-type="web-server"]

# Message and Predicate

[class="alert", severity=6,  
device-type="web-server",  
alert-type="hardware failure"]

[alert-type="intrusion"  $\wedge$   
severity>2  $\vee$  class="alert"  $\wedge$   
device-type="web-server"]

# Application

- Publish/Subscribe event notification
- System Monitoring Management
- Sensor Network
- Data Sharing

# Overlay Network

- Build on top of an other network
- Connected by Logical Link
- Logical link can correspond to one or several physical link in the underlying network
- Example: JXTA (Sun)  
Solipsis (France Telecom)  
Gnutella  
DHT (Chord, Pastry, Tapestry)

- One-to-one association between filters and interfaces
- $I_s$  is an interface
- $f_{s,t}$  is a filter
- constraints in the third column
- Use the *counting algorithm* to determine which filters match the message

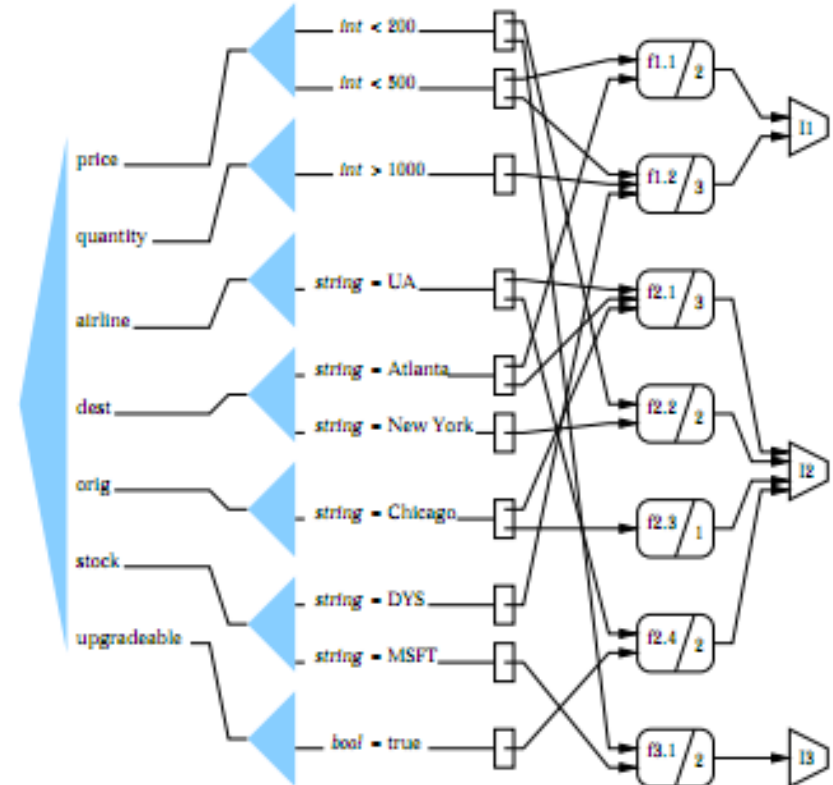

$I_1$	$f_{1,1}$	<i>string</i> $dest = Milano$ <i>int</i> $price < 500$
	$f_{1,2}$	<i>string</i> $stock = DYS$ <i>int</i> $quantity > 1000$ <i>int</i> $price < 500$
$I_2$	$f_{2,1}$	<i>string</i> $airline = UA$ <i>string</i> $orig = Denver$ <i>string</i> $dest = Milano$
	$f_{2,2}$	<i>string</i> $dest = New York$ <i>int</i> $price < 200$
	$f_{2,3}$	<i>string</i> $orig = Denver$
	$f_{2,4}$	<i>string</i> $airline = UA$ <i>bool</i> $upgradeable = true$
$I_3$	$f_{3,1}$	<i>string</i> $stock = MSFT$ <i>int</i> $price < 200$

# Forwarding table

- Organized in two parts left-to-right
- Left side
  - all individuals constraints associated with neighbours router
  - connected to the right side as boolean input
- Right side
  - conjunction of constraints into filter
  - disjunction of filter into predicates of interface

# Counting algorithm

- Iterates through all attributes
- Find constraints matched
- Iterate through matched constraints to find matched filters

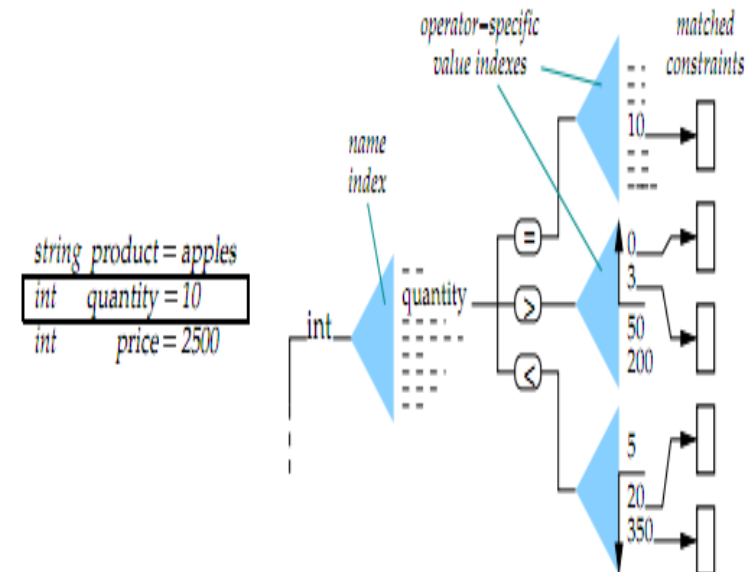

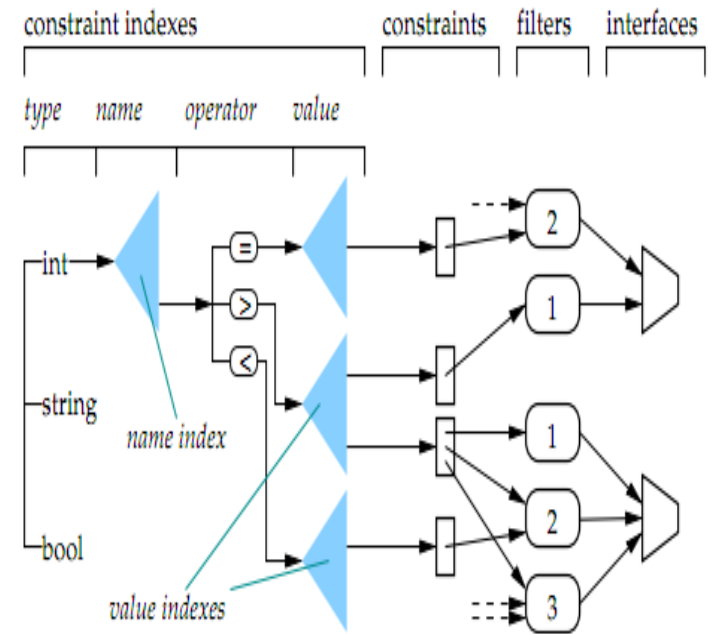

# Counting algorithm

- Algorithm
  - use 2 data structures
    - tables of counters for partially matched filters
    - set containing interface to which the message should be forwarded
  - for each constraints found through the constraints index, the algorithm increments the counter of all filters linked to that constraint
  - when the counter equals the number of constraints linked to it, the filter is satisfied and the interface can be added to the set of matched interface

# Index based optimisation

- Switch on the type of an attribute
- TST on the name of the attribute
- Specific optimization related to the type of the attribute are done to index constraint (lesser than for integer constraint sorted)

# In the case of string

- Support operators =, <, >, suffix, prefix and substring all in a single index
- See the paper for more details

# Attribute Selectivity

- Save time by eliminating from consideration ASAP
- Given an attribute **a** and an interface **I**, **a** is determinant if every filter of interface **I** contains at least one constraint on **a**
- Selectivity table associate attributes with the interface for which they are determinant
- Check this table as pre-process phase to eliminate interfaces that will not match (for example, if at

# An other solution PST

## Matching Events in a Content-based Subscription System

Marcos K. Aguilera, Robert E. Strom, Daniel C. Sturman, Mark Astley and Tushar D. Chandra

# Existing Approach

- Flooding approach: message are send to everyone and clients filter what they receive
- Match first approach: message is matched against all filter list to generate a destination list and then the message is routed to all entry on this list

**( $a_1=1$  &&  $a_2=2$  &&  $a_3=3$  &&  $a_5=3$ )**

$a = \langle 1, 2, 3, 1, 2 \rangle$

# Notes

- Other type of test than equality can be performed
- The order in which the attribute are ordered for root to leaf is arbitrary
  - however, the algorithm performs better if the attribute near the root have the fewest "\*"

# Distributed Improvement

## An Efficient Multicast Protocol for Content-Based Publish-Subscribe System

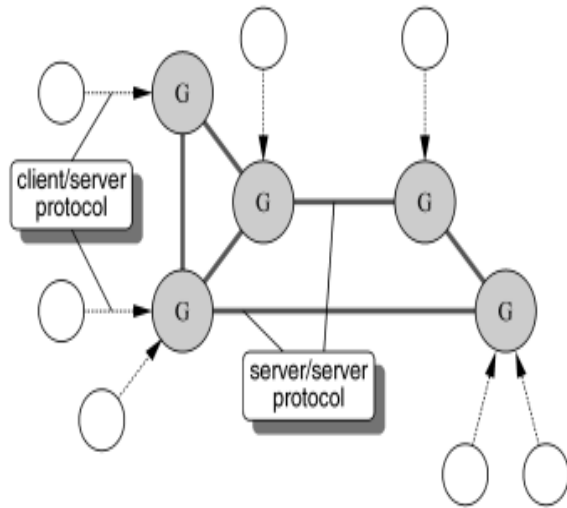

Guruduth Banavar, Tushar Chandra, Bodhi Mukherjee, Jay Nagarajarao, Robert E. Strom, and Daniel C. Sturma

# Related consideration

## Design and Evaluation of a Wide-Area Event Notification Service

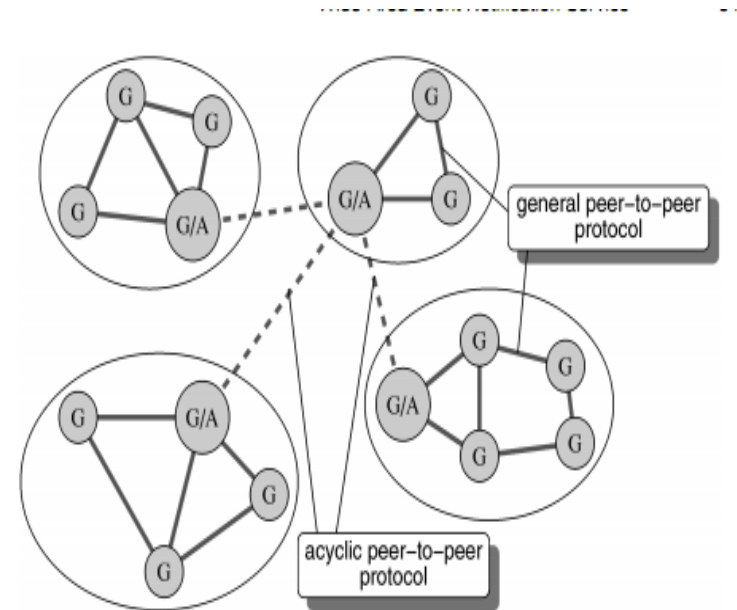

ANTONIO CARZANIGA, DAVID S. ROSENBLUM and ALEXANDER L. WOLF

# Architecture

The paper presented assumed an acyclic topology

# Hybrid Architecture

The routing or forwarding algorithm to be used depends on the topology

# Question ?

Merci
