

BACKGROUND

Human visual system undergoes various changes with age including loss of photoreceptor sensitivity, reduction in pupillary area, increase in ocular media density, and neuronal cell death.

Physiological and neural changes in the visual system with age also lead to changes in contrast sensitivity. Various studies have shown age-related changes in spatio-chromatic contrast sensitivity.

Our study investigates the senescence of spatio-chromatic sensitivity including the effect of adapting light level using a high dynamic range (HDR) display under normal viewing conditions.

2

METHODOLOGY

STIMULI

- Gabor patches with fixed number of cycles
- Spatial frequencies: 0.5, 1, 2, 4, and 6 cpd
- Color modulations: (1) Black-white; (2) Red-green; (3) Lime-Violet
- Mean background luminances: 0.02, 0.2, 2, 20, 200, 2000, and 7000 cd/m²

OBSERVERS

- Color normal observers
- 20 young participants; mean age: 33 years
- 20 older participants; mean age: 65 years

PSYCHOPHYSICAL TASK

- 4AFC QUEST-based detection task
- Initial contrast threshold estimate using method of adjustment
- Single mean background luminance for each session to ensure adaptability
- 5 spatial frequencies and 3 color directions interleaved within each session
- Viewing distance: 91 cm
- Display size: 12.5 x 9.4 visual degrees

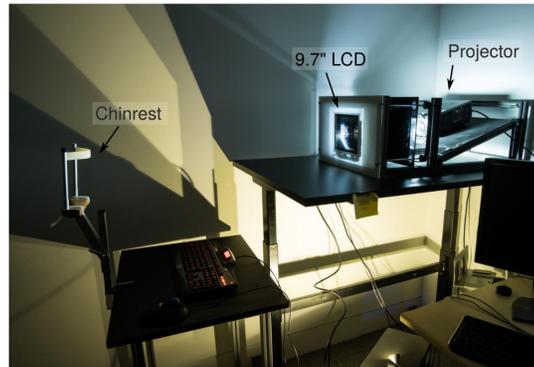

FOCUS GROUP

- 2 focus groups with 3, and 4 observers aged above 60 respectively
- Topics: Most important display attributes w.r.t to perceived image quality, user experience, display adaptability

1

APPARATUS

HDR DISPLAY SYSTEM

- Custom-built HDR displays
- Peak luminance: 4,000 cd/m²
- Consisting of an LCD panel and a DLP backlight
- Size: 2048x1536 px
- Maximum contrast: 1,000,000:1

3

RESULTS

GENERAL TREND

- Contrast sensitivity:
 - o Increases with background luminance up to around 200 cd/m²
 - o Declines after 200 cd/m² in luminance channel
 - o Becomes constant after 200 cd/m² in chromatic channels

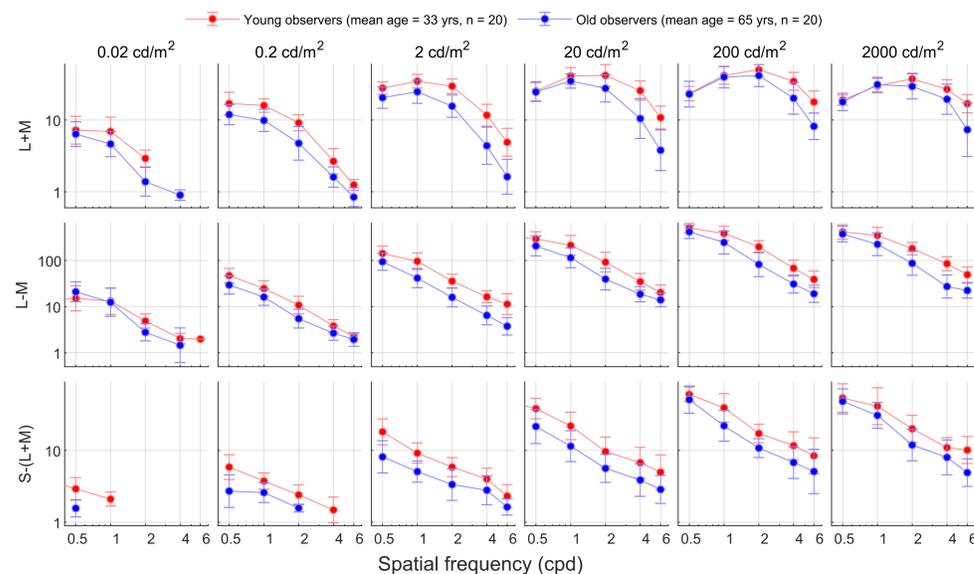

Figure 3. Comparison of mean contrast sensitivity measurements (error bars: standard deviation) from younger and older observers' age group.

AGE-RELATED CHANGES IN SPATIO-CHROMATIC CONTRAST SENSITIVITY AT MESOPIC AND PHOTOPIC LIGHT LEVELS

AGE DEPENDENCE

- Sensitivity of younger observers is roughly 0.3 log units higher than older observers
- The difference is roughly constant across colour directions and light levels
- In achromatic channel, older observers show larger decline in sensitivity for higher spatial frequencies at high photopic light levels
- Peak sensitivity and cut-off frequency of CMFs decrease with age
- Rate of decrease in peak sensitivity and cut-off frequency is luminance dependent

4

CONCLUSIONS

- Both chromatic and achromatic contrast sensitivities are affected by age
- At lower luminances, the effect of age is frequency-invariant
- At higher luminances, sensitivity of higher spatial frequencies are deteriorated with age more than that of lower frequencies

5

FUTURE WORK

- Investigating and predicting suprathreshold sensitivity in observers of different age groups
- Developing a computational model with spatial frequency, stimulus size, background luminance, and observer age as parameters
- Developing an application for orthoptic assessment for people in older age groups
