#### Motivation

In this part of the course we're examining several methods of higher-level program analysis.

We have so far seen abstract interpretation and constraintbased analysis, two general frameworks for formally specifying (and performing) analyses of programs.

Another alternative framework is inference-based analysis.

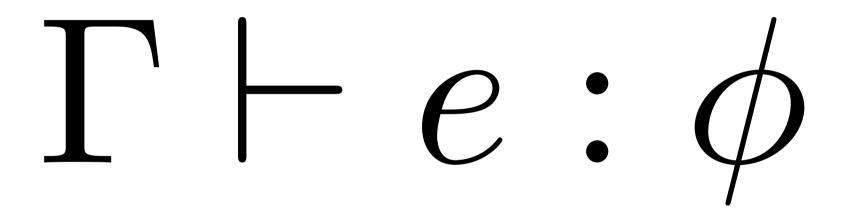

## Inference-based analysis

Inference systems consist of sets of rules for determining program properties.

Typically such a property of an entire program depends recursively upon the properties of the program's subexpressions; inference systems can directly express this relationship, and show how to recursively compute the property.

#### Inference-based analysis

An inference system specifies judgements:

- e is an expression (e.g. a complete program)
- Γ is a set of assumptions about free variables of e
- φ is a program property

Consider the ML type system, for example.

This particular inference system specifies judgements about a well-typedness property:

$$\Gamma \vdash e : t$$

means "under the assumptions in  $\Gamma$ , the expression e has type t".

We will avoid the more complicated ML typing issues (see Types course for details) and just consider the expressions in the lambda calculus:

$$e := x | \lambda x. e | e_1 e_2$$

Our program properties are types t:

$$t := \alpha \mid int \mid t_1 \rightarrow t_2$$

 $\Gamma$  is a set of type assumptions of the form

$$\{x_1:t_1,...,x_n:t_n\}$$

where each identifier  $x_i$  is assumed to have type  $t_i$ .

We write

$$\Gamma[x:t]$$

to mean  $\Gamma$  with the additional assumption that x has type t (overriding any other assumption about x).

In all inference systems, we use a set of *rules* to inductively define which judgements are valid.

In a type system, these are the typing rules.

$$\frac{}{\Gamma[x:t] \vdash x:t} \quad \text{(VAR)}$$

$$\frac{\Gamma[x:t] \vdash e:t'}{\Gamma \vdash \lambda x.e:t \to t'} \quad \text{(LAM)}$$

$$\frac{\Gamma \vdash e_1 : t \to t' \quad \Gamma \vdash e_2 : t}{\Gamma \vdash e_1 e_2 : t'} \quad (APP)$$

```
\Gamma = \{ 2 : int, add : int \rightarrow int \rightarrow int, multiply : int \rightarrow int \}
e = \lambda x. \lambda y. add (multiply 2 x) y
t = ?
```

```
\Gamma = \{ 2 : int, add : int \rightarrow int \rightarrow int, multiply : int \rightarrow int \rightarrow int \}
   e = \lambda x. \lambda y. add (multiply 2 x) y
    t = int \rightarrow int \rightarrow int
\Gamma[x:int][y:int] \vdash add:int \rightarrow int \rightarrow int \quad \Gamma[x:int][y:int] \vdash multiply \ 2x:int
                  \Gamma[x:int][y:int] \vdash add \ (multiply \ 2 \ x):int \rightarrow int
                                                                                                     \Gamma[x:int][y:int] \vdash y:int
                                                \Gamma[x:int][y:int] \vdash add \ (multiply\ 2\ x)\ y:int
```

 $\Gamma[x:int] \vdash \lambda y. \ add \ (multiply \ 2 \ x) \ y:int \rightarrow int$ 

 $\Gamma \vdash \lambda x. \, \lambda y. \, add \, (multiply \, 2 \, x) \, y : int \rightarrow int \rightarrow int$ 

### Optimisation

In the absence of a compile-time type checker, all values must be tagged with their types and run-time checks must be performed to ensure types match appropriately.

If a type system has shown that the program is well-typed, execution can proceed safely without these tags and checks; if necessary, the final result of evaluation can be tagged with its inferred type.

Hence the final result of evaluation is identical, but less run-time computation is required to produce it.

# Safety

The safety condition for this inference system is

$$(\{\} \vdash e : t) \Rightarrow (\llbracket e \rrbracket \in \llbracket t \rrbracket)$$

where [e] and [t] are the denotations of e and t respectively: [e] is the value obtained by evaluating e, and [t] is the set of all values of type t.

This condition asserts that the run-time behaviour of the program will agree with the type system's prediction.

Type-checking is just one application of inference-based program analysis.

The properties do not have to be types; in particular, they can carry more (or completely different!) information than traditional types do.

We'll consider a more program-analysis-related example: detecting odd and even numbers.

This time, the program property  $\varphi$  has the form

$$\phi := odd \mid even \mid \phi_1 \rightarrow \phi_2$$

$$\frac{}{\Gamma[x:\phi] \vdash x:\phi} \quad \text{(VAR)}$$

$$\frac{\Gamma[x:\phi] \vdash e:\phi'}{\Gamma \vdash \lambda x.e:\phi \to \phi'} \quad \text{(LAM)}$$

$$\frac{\Gamma \vdash e_1 : \phi \to \phi' \quad \Gamma \vdash e_2 : \phi}{\Gamma \vdash e_1 e_2 : \phi'} \quad (APP)$$

```
\Gamma = \{ 2 : \text{even}, \text{add} : \text{even} \rightarrow \text{even} \rightarrow \text{even}, \\ \text{multiply} : \text{even} \rightarrow \text{odd} \rightarrow \text{even} \}
e = \lambda x. \lambda y. \text{add (multiply 2 } x) \text{ y}
\phi = ?
```

```
\Gamma = \{ 2 : \text{even, add} : \text{even} \rightarrow \text{even} \rightarrow \text{even,} \\ \text{multiply} : \text{even} \rightarrow \text{odd} \rightarrow \text{even} \}
e = \lambda x. \lambda y. \text{add (multiply 2 } x) \text{ y}
\phi = \text{odd} \rightarrow \text{even} \rightarrow \text{even}
```

```
\frac{\Gamma[x:odd][y:even] \vdash add:even \rightarrow even \quad }{\Gamma[x:odd][y:even] \vdash multiply \ 2 \ x:even} = \frac{\Gamma[x:odd][y:even] \vdash add \ (multiply \ 2 \ x):even \rightarrow even }{\Gamma[x:odd][y:even] \vdash add \ (multiply \ 2 \ x):even} = \frac{\Gamma[x:odd][y:even] \vdash add \ (multiply \ 2 \ x):even}{\Gamma[x:odd] \vdash \lambda y. \ add \ (multiply \ 2 \ x):even \rightarrow even} = \frac{\Gamma[x:odd] \vdash \lambda y. \ add \ (multiply \ 2 \ x):even \rightarrow even}{\Gamma[x:odd] \vdash \lambda y. \ add \ (multiply \ 2 \ x):even \rightarrow even} = \frac{\Gamma[x:odd] \vdash \lambda y. \ add \ (multiply \ 2 \ x):even \rightarrow even}{\Gamma[x:odd] \vdash \lambda y. \ add \ (multiply \ 2 \ x):even \rightarrow even} = \frac{\Gamma[x:odd] \vdash \lambda y. \ add \ (multiply \ 2 \ x):even \rightarrow even}{\Gamma[x:odd] \vdash \lambda y. \ add \ (multiply \ 2 \ x):even \rightarrow even} = \frac{\Gamma[x:odd] \vdash \lambda y. \ add \ (multiply \ 2 \ x):even \rightarrow even}{\Gamma[x:odd] \vdash \lambda y. \ add \ (multiply \ 2 \ x):even \rightarrow even} = \frac{\Gamma[x:odd] \vdash \lambda y. \ add \ (multiply \ 2 \ x):even \rightarrow even}{\Gamma[x:odd] \vdash \lambda y. \ add \ (multiply \ 2 \ x):even \rightarrow even} = \frac{\Gamma[x:odd] \vdash \lambda y. \ add \ (multiply \ 2 \ x):even \rightarrow even}{\Gamma[x:odd] \vdash \lambda y. \ add \ (multiply \ 2 \ x):even \rightarrow even}
```

# Safety

The safety condition for this inference system is

$$(\{\} \vdash e : \phi) \Rightarrow (\llbracket e \rrbracket \in \llbracket \phi \rrbracket)$$

where  $[\![ \varphi ]\!]$  is the denotation of  $\varphi$ :

## Richer properties

Note that if we want to show a judgement like

```
\Gamma \vdash \lambda x. \lambda y. \ add \ (multiply \ 2 \ x) \ (multiply \ 3 \ y) : even \rightarrow even \rightarrow even
```

we need more than one assumption about multiply:

```
\Gamma = \{ ..., multiply : even \rightarrow even \rightarrow even, multiply : odd \rightarrow even \rightarrow even, ... \}
```

## Richer properties

This might be undesirable, and one alternative is to enrich our properties instead; in this case we could allow *conjunction* inside properties, so that our single assumption about *multiply* looks like:

multiply: even 
$$\rightarrow$$
 even  $\rightarrow$  even  $\land$  even  $\rightarrow$  odd  $\rightarrow$  even  $\land$  odd  $\rightarrow$  even  $\rightarrow$  even  $\land$  odd  $\rightarrow$  odd  $\rightarrow$  odd

We would need to modify the inference system to handle these richer properties.

### Summary

- Inference-based analysis is another useful framework
- Inference rules are used to produce judgements about programs and their properties
- Type systems are the best-known example
- Richer properties give more detailed information
- An inference system used for analysis has an associated safety condition
