 $O(n \log n)$ algorithm.

constant multiple of n^2 .

solve the same problem.

The first half of this statement is short for:

Lower and Upper Bounds

What is the running time complexity of the fastest algorithm that sorts a list?

By the analysis of the Merge Sort algorithm, we know that this is no worse than $O(n \log n)$.

The complexity of a particular algorithm establishes an *upper bound* on the complexity of the problem.

To establish a *lower bound*, we need to show that no possible algorithm, including those as yet undreamed of, can do better.

In the case of sorting, we can establish a lower bound of $\Omega(n \log n)$, showing that Merge Sort is asymptotically optimal.

Sorting is a rare example where known upper and lower bounds match.

Review		Lower Bound on Sorting	

The complexity of an algorithm (whether measuring number of steps, or amount of memory) is usually described asymptotically:

Algorithms and Problems

Insertion Sort runs in time $O(n^2)$, while Merge Sort is an

If we count the number of steps performed by the Insertion

such number, from among all inputs of that size, then the

It makes sense to compare the two algorithms, because they seek to

Sort algorithm on an input of size n, taking the largest

function of n so defined is eventually bounded by a

But, what is the complexity of the sorting problem?

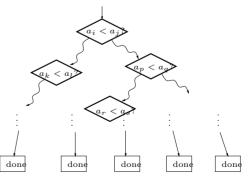

Definition

For functions $f : \mathbb{N} \to \mathbb{N}$ and $g : \mathbb{N} \to \mathbb{N}$, we say that:

- f = O(g), if there is an $n_0 \in \mathbb{N}$ and a constant c such that for all $n > n_0$, $f(n) \le cg(n)$;
- $f = \Omega(g)$, if there is an $n_0 \in \mathbb{N}$ and a constant c such that for all $n > n_0$, $f(n) \ge cg(n)$.
- $f = \theta(g)$ if f = O(g) and $f = \Omega(g)$.

Usually, O is used for upper bounds and Ω for lower bounds.

An algorithm A sorting a list of n distinct numbers a_1, \ldots, a_n .

To work for all permutations of the input list, the tree must have at least n! leaves and therefore height at least $\log_2(n!) = \theta(n \log n)$.

Given

• V — a set of nodes.

is the smallest possible.

• $c: V \times V \to \mathbb{N}$ — a cost matrix.

Travelling Salesman

 $c(v_n, v_1) + \sum_{i=1}^{n-1} c(v_i, v_{i+1})$

Find an ordering v_1, \ldots, v_n of V for which the total cost:

9

Complexity of TSP

Obvious algorithm: Try all possible orderings of V and find the one with lowest cost. The worst case running time is $\theta(n!)$.

Lower bound: An analysis like that for sorting shows a lower bound of $\Omega(n \log n)$.

Upper bound: The currently fastest known algorithm has a running time of $O(n^2 2^n)$.

Between these two is the chasm of our ignorance.
