Mobile and Sensor Systems

Lecture 3: Infrastructure, Ad-hoc and
Delay Tolerant Mobile Networks
Dr Cecilia Mascolo

UNIVERSITY OF
CAMBRIDGE

In this lecture

- In this lecture we will describe the difference in infrastructure and ad hoc networks and we will introduce ad hoc routing protocols.

- We will also introduce disconnected ad hoc networks and delay tolerant routing protocols.
Infrastucture-based sv Ad-hoc

- Wireless communication can be organized in two different fashions :
  - This might depend on the application and on the network set up.

UNIVERSITY OF CAMBRIDGE

3

Infrastructure-based

infrastructure mode

- ❖ base station connects mobiles into wired network
- ❖ handoff: mobile changes base station providing connection into wired network

network infrastructure

UNIVERSITY OF CAMBRIDGE
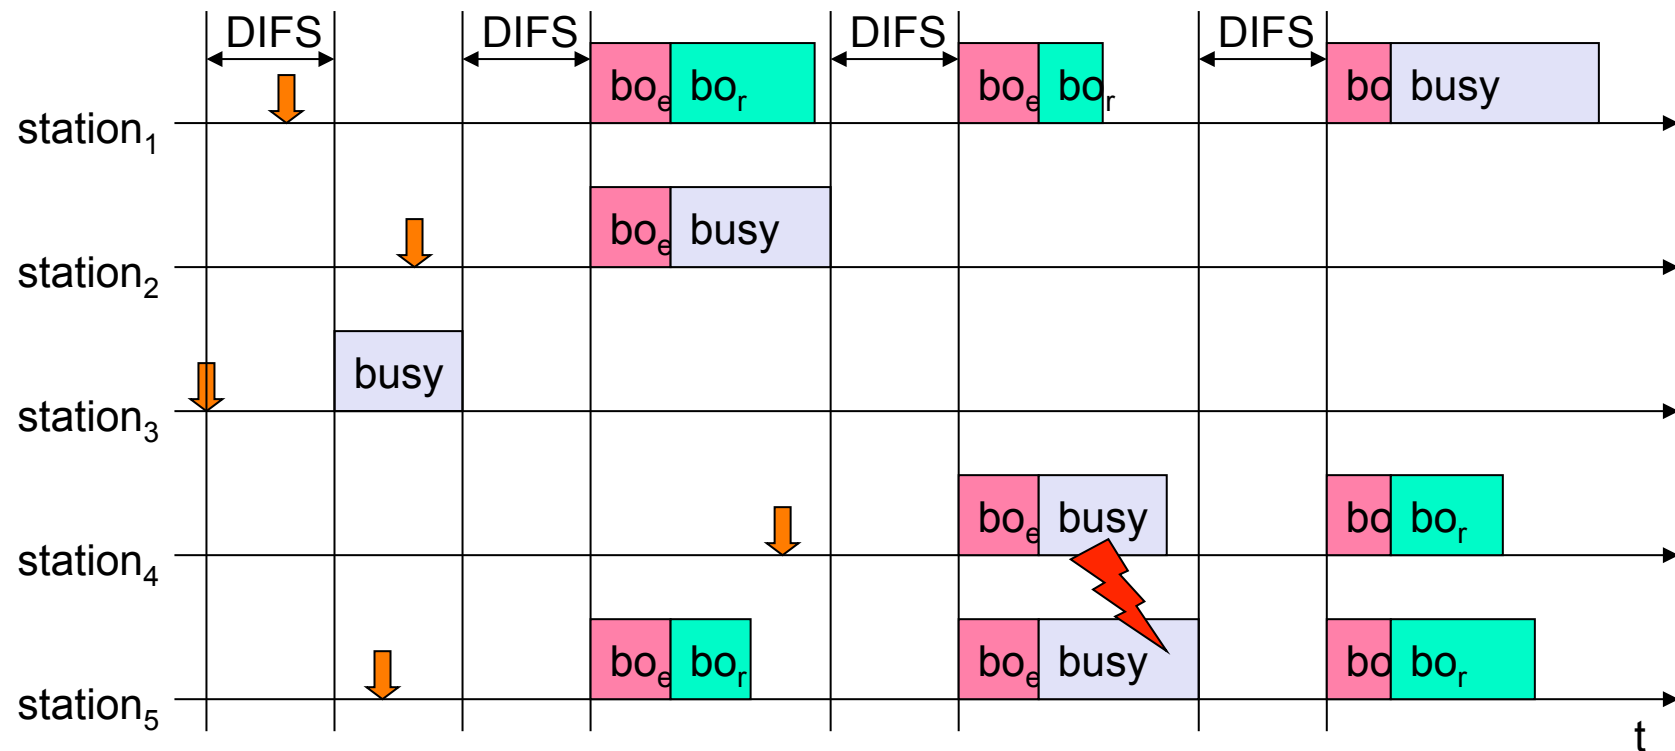

4

Ad-hoc

ad hoc mode

- ❖ no base stations
- ❖ nodes can only transmit to other nodes within link coverage
- ❖ nodes organize themselves into a network: route among themselves

UNIVERSITY OF
CAMBRIDGE

802.11 - MAC layer (recap)

- Priorities
  - defined through different inter frame spaces
  - no guaranteed, hard priorities
  - SIFS (Short Inter Frame Spacing)
    - highest priority, for ACK, CTS, polling response
  - PIFS (PCF IFS)
    - medium priority, for time-bounded service using PCF
  - DIFS (DCF, Distributed Coordination Function IFS)
    - lowest priority, for asynchronous data service

DIFS

DIFS

PIFS

SIFS

medium busy   contention   next frame

802.11 – competing stations

Synchronization using a Beacon (infrastructure)

beacon interval
(20ms – 1s)

access
point

medium

t

▽ value of the timestamp   B beacon frame
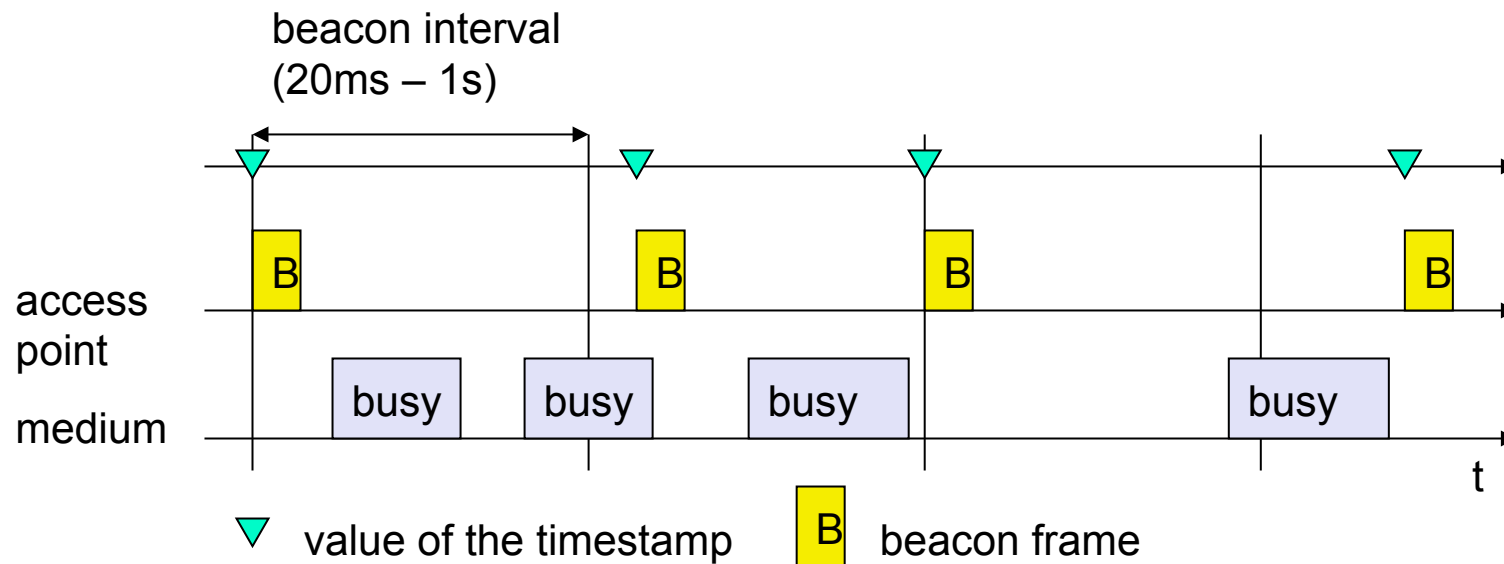

- Nodes need to keep a tight synchronized clock with the access point: this is useful for power management and coordination of frequency hopping or contention slots.
- Beacons are sent semi-periodically [ei when the medium is not busy]
UNIVERSITY OF CAMBRIDGE

# Synchronization using a Beacon (ad-hoc)

- In ad hoc mode each station transmits a beacon after the beacon interval [semi periodic again]
- Random backoffs are applied to beacons too: all station adjust clock to beacons received and suppress their beacon for the beacon interval

Power saving with wake-up patterns (infrastructure)

TIM interval

DTIM interval

access point

D B   T   T d   D B

medium

busy   busy   busy   busy

station

p d

| T | TIM | D | DTIM | | awake |

| B | broadcast/multicast | p | PS poll | d | data transmission to/from the station |

TIM: list of stations for which there will be data in the slot
DTIM Interval indicates the delivery traffic indication map: for broadcast and multicast frames. It's a multiple of TIM

t

UNIVERSITY OF CAMBRIDGE

Power saving with wake-up patterns (ad-hoc)
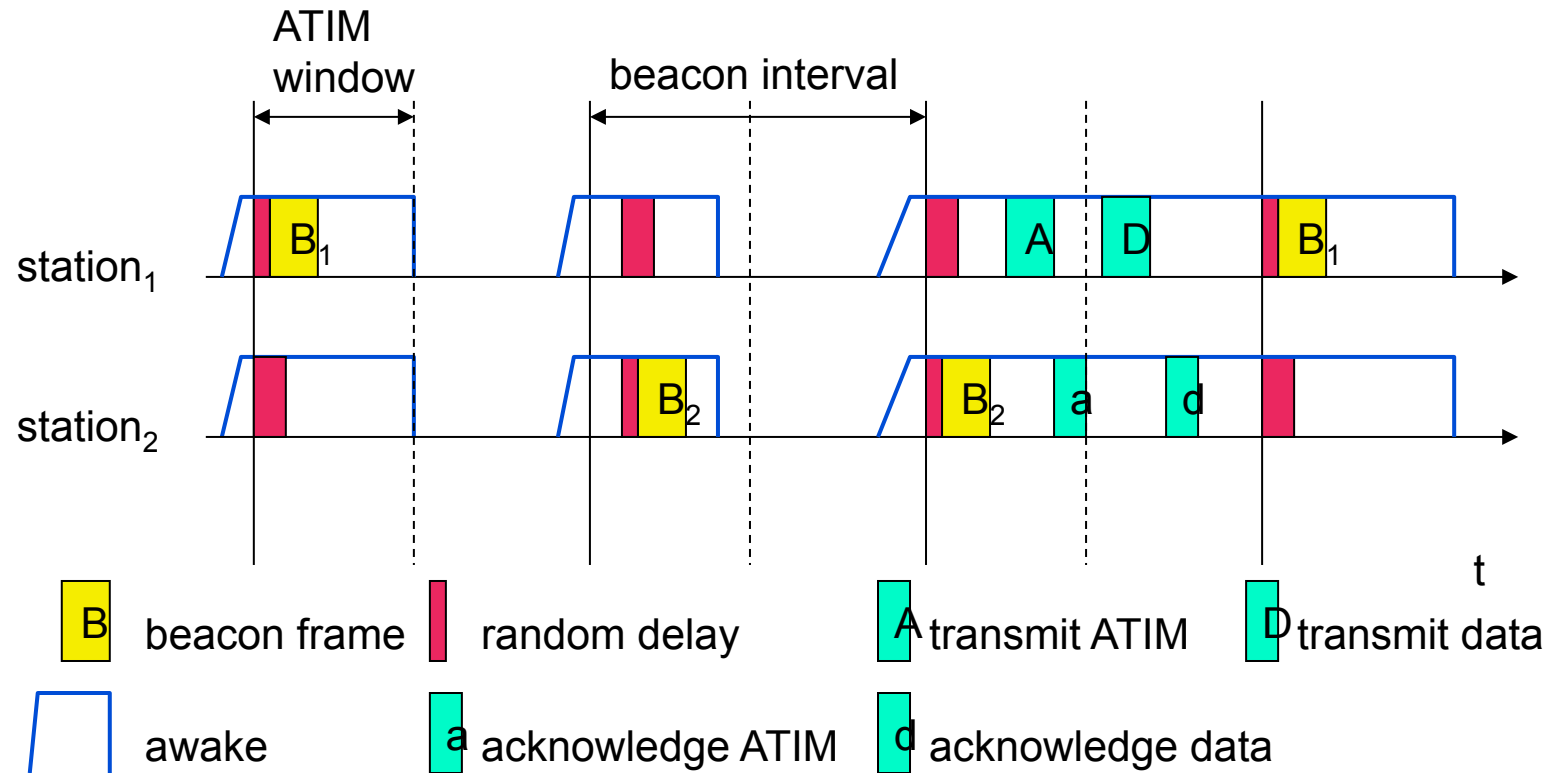

ATIM is the transmission map for ad hoc traffic: all stations stay awake for this slot

UNIVERSITY OF CAMBRIDGE

Examples of Multi-hop Ad hoc Networks
A schematic of an ad hoc network
Note that this is a static snapshot: the network will be reconfiguring when nodes move.

UNIVERSITY OF CAMBRIDGE

Examples of Ad-hoc Networking

- Destination Sequenced Distance Vector (**DSDV**) Routing.

- Proactive: routes are maintained also when not needed. Each node maintains a table with a route to every node.

- Each entry of the table has a sequence number assigned by the destination.

Dest. Next Hop, Hops Required, Dest. Seq. number.

UNIVERSITY OF
CAMBRIDGE

DSDV: Routing Table for Node D

| Dest	Nexthop	Hops	SequenceN
A	B	2	406
B	B	1	128
C	B	2	564
D	D	0	710
E	F	2	392
F	F	1	076
G	F	2	128
H	F	3	050

UNIVERSITY OF
CAMBRIDGE
DSDV Routing Updates

- Each node periodically transmits updates.
- Includes its own sequences number, routing table updates.
- Nodes also send routing table updates for some incremental link changes.
- When two routes to a destination received from two different neighbors, choose the one with *greatest* destination sequence number.
- If equal (when would they be equal?), choose the smaller metric (hop count).

DSDV: When a new link appears (ie a node moved closer)

- When K joins it
  - Transmits routing table <K,K,0,101>
  - Node A receives it and inserts in routing table: <K,K,1,101>
  - Node A propagates the new route to neighbours.
  - Neighbours of A update table with <K,A,2,101> and continue propagation.
DSDV: When a link breaks
# (ie a node moves away)

- The link between D and F breaks (the two nodes move apart or the wireless link has no connection for other reasons).

- Node D notices the break (eg lack of table update from F):

  – Updates hop count to F to infinity.

  – Increments the sequence number for F,E,G,H

  – Then:

UNIVERSITY OF
CAMBRIDGE
DSDV: When a link breaks
(ie a node moves away)

– Then Node D sends updates with new route information:

- <F, -, ∞, 077>
- <E, -, ∞, 393>
- <G, -, ∞, 129>
- <H, -, ∞, 051>
DSDV: Limitations

- Circulating and maintaining table updates is expensive for the network.

    – Especially if this is battery powered.

- If the network changes a lot then these updates might be worthwhile but only if all nodes need to communicate to all others

    – Why would a node need to keep updates of routes to nodes it does not need to communicate with?

UNIVERSITY OF
CAMBRIDGE

Another Ad-hoc routing example
Dynamic Source Routing (DSR)

- DSR is a reactive protocol: routes are searched only when communication with a node is needed.

- When a node needs to communicate it sends a route request packet.

- Nodes receive it and add themselves to the path and propagate the request to their neighbours.

- Eventually the destination node is found and the path is sent back to the source (how?).

UNIVERSITY OF
CAMBRIDGE

DSR example

- Node A needs to communicate with F. Sends request <A,F, [-],101>.
- Node B receives the request and forwards:
  - <A,F,[B],101>.
- Node D receives it and forwards:
  - <A,F,[B,D],101>.
- Node F receives it and ? (continued).
DSR example (continued)

- Node F receives it and:
  - If links are symmetric sends the path back following the indicated inverse route.
  - Or, if it has cached a path to A uses it.
  - Otherwise it sends a route request for A.
DSR Comments

- Sequence numbers are used to avoid routing loops.

- Routes are cached for some time to avoid frequent route requests by intermediate nodes.

- Low mobility and low traffic are the best scenarios for this protocol.

UNIVERSITY OF CAMBRIDGE

# Hybrid Solutions
Zone Routing Protocol (ZRP)

- Zone routing is a hybrid protocol which combines proactive with reactive approaches.

- A zone around node N is maintained where routes are collected proactively.

- Beyond the zone an inter zone protocol is responsible to determine the routes in a reactive way.

UNIVERSITY OF CAMBRIDGE

Disconnected Ad-hoc Networks

- The protocols we have seen until now only work when there is a "connected path" among the communicating nodes

- I.e. no storage on intermediate nodes is allowed.

- The protocols do not work when this is not the case.

Connected vs Disconnected Ad-hoc Networks

Connected: there is a connected path among each couple
Disconnected: not all links are present at the same time

t10

UNIVERSITY OF
CAMBRIDGE
Delay Tolerant Networks and Protocols

- These protocols do not assume a temporally connected path among the nodes.

- Nodes can accept a packet and deliver it later, after some time storing it.
UNIVERSITY OF
CAMBRIDGE

Example: Epidemic Routing

- A flooding protocol which allows nodes to store packets before forwarding.

- A node accepts a packet, moves while carrying the packet and then forwards at a different time to a different neighbourhood.

- Flooding is always expensive (many transmissions, large buffers needed)

Example
Example continued

Can we do better?

- Exploit the knowledge on the mobility of the nodes

- Is the mobility deterministic (ie. Always on the same path at same times like busses)? Maybe we can even control the mobility of some of the nodes!

- If not fixed, is it at least predictable?

- If not predictable, random…

UNIVERSITY OF
CAMBRIDGE

When mobility is predictable

- Prediction of mobility techniques need to be applied unless you want to use "epidemic".

- Instead of blindly forwarding packets to all or some neighbors, intermediate nodes estimate the chance, for each outgoing link, of eventually reaching the destination.

- Based on this estimation, the intermediate nodes decide whether to store the packet and wait for a better chance, or decide to which nodes (and the time) to forward.

UNIVERSITY OF CAMBRIDGE

Context Aware Routing (CAR)

- A node chooses the best carrier to reach a specific node. How is the best carrier neighbour chosen?

  - Host mobility, host colocation with destination node, battery.

  - A utility function which weights these aspects

  - Kalman Filter is used to predict future host colocation with destination based on previous history.

- The approach is based on local knowledge only.
