- vi. Decision. The results of this study of the effect of a film upon opinion are summarized attitudes changed after viewing the film to have increased their judgment and about half change. If the film had no systematic effect, we would expect about half of those whose would expect about 42.5 to show one kind of change and 42.5 to show the other change. to have decreased their judgment. That is, of the 85 people whose attitudes changed, we did not change and 85 who did. The analysis is based only on those subjects who did in Table 5.5. Did the film have any effect? The data show that there were 15 adults who Eq. (5.4), and noting that x > N/2 (that is, 59 > 42.5), we have that, when H_0 is true, a split as extreme or more extreme could occur by chance. Using Now we observe that 59 decreased and 26 increased. We may determine the probability

$$z = \frac{2x \pm 1 - N}{\sqrt{N}}$$

$$z = \frac{118 - 1 - 85}{\sqrt{85}}$$

$$z = \frac{3.77}{\sqrt{85}}$$

systematic effect on adults' attitudes regarding the severity of punishment desirable for of the alternative hypothesis. We conclude from these data that the film had a significant values are for a one-tailed test, whereas the region of rejection in this case is two-tailed.) is 2(.0003) = .0006. (The probability shown in the table is doubled because the tabled Juvenile delinquents. Since .0006 is smaller than $\alpha = .01$, the decision is to reject the null hypothesis in favor Reference to Appendix Table A reveals that the probability $|z| \ge 3.47$ when H_0 is true

totals are separate but not independent representations of the same data. require that we also know the separate frequencies B and C.3 It is not too uncomrectly. The data in Table 5.5 are cast in terms of the variables of interest. A fourfold cation of the sign test but also because data of this sort are often analyzed incorthey represented independent samples. This is not the case; the row and column mon for researchers to analyze such data by using the row and column totals as if table could be constructed which contained the same information, but would This example was included not only because it demonstrates a useful appli-

significance of changes (Sec. 5.1). With the use of the data in Table 5.5. This example could also have been analyzed by the McNemar test for the

$$X^{2} = \frac{(|A - D| - 1)^{2}}{|A + D|} \quad \text{with } df = 1$$

$$= \frac{(|59 - 26| - 1)^{2}}{|59 + 26|}$$

$$= 12.05$$
(5.2)

(that is, no correction for continuity is made in either case), then z^2 will be identical Appendix Table C shows that $X^2 \ge 12.05$ with df = 1 has a probability of occurto X^2 for any set of data. The same is true if the calculations are made by using that, if z is computed by using Eq. (5.3) and if X^2 is computed by using Eq. (5.1) the limitations of the table of the chi-square distribution used. It should be noted yielded by the sign test. The slight difference between the two results is due to rence when H_0 is true of less than .001. This finding is not in conflict with that the correction for continuity [Eqs. (5.2) and (5.4)].

5.2.5 Summary of Procedure

These are the steps in the use of the sign test:

- 1. Determine the sign of the difference between the two members of each pair.
- By counting, determine the value of N equal to the number of pairs whose differences show a sign (ties are ignored).
- The method for determining the probability of occurrence of data as extreme or more extreme when H_0 is true depends on the size of N:
- Appendix Table D. fewer signs. For a two-tailed test, double the probability value obtained from associated with a value as small as the observed value of x = the number of (a) If N is 35 or smaller, Appendix Table D shows the one-tailed probability
- (b) If N is larger than 35, compute the value of z by using Eq. (5.4a). Appendix Table A gives one-tailed probabilities associated with values as extreme as

in Appendix Table A. various values of z. For a two-tailed test, double the probability values shown

4. If the probability yielded by the test is less than or equal to α , reject H_0 .

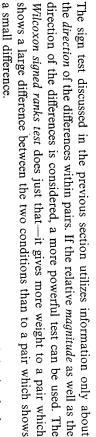

5.2.6 Power-Efficiency

cent. Discussions of the power-efficiency of the sign test for large samples may be as the size of the sample increases to an eventual (asymptotic) efficiency of 63 perfound in Lehmann (1975). The power-efficiency of the sign test is about 95 percent for N=6, but it declines

5.2.7 References

For other discussions of the sign test, the reader should consult Dixon and Massey (1983), Lehmann (1975), Moses (1952), and Randles and Wolfe (1979).

THE WILCOXON SIGNED RANKS TEST

can make the judgment of "greater than" between any pair's two values as well any pair, and (2) rank the differences in order of absolute size. That is, the researcher which member of a pair is "greater than," i.e., tell the sign of the difference between mation the experimenter may use the Wilcoxon signed ranks test. as between any two difference scores arising from any two pairs. With such infortist. With behavioral data, it is not uncommon that the researcher can (1) tell The Wilcoxon signed ranks test is a very useful test for the behavioral scien-

TABLE A

Probabilities associated with the upper tail of the normal distribution

The body of the table gives one-tailed probabilities under H_0 of z. The left-hand marginal column gives various values of z to one decimal place. The top row gives various values to the second decimal place. Thus, for example, the one-tailed p of $z \ge .11$ or $z \le -.11$ is p = .4562.

TABLE A_n Critical z values for #c multiple comparisons*

Entries in the table for a given #c and level of significance α is the point on the standard normal distribution such that the upper-tail probability is equal to $\frac{1}{2}\alpha/\#c$. For values of #coutside the range included in the table, z can be found by using Appendix Table A.

^{* #}c is the number of comparisons.

TABLE A_{III}

Critical values $q(\alpha, \# c)$ for # c dependent multiple comparisons*†‡

Entries in the table for a given # c and level of significance α are critical values for the maximum absolute values of # c standard normal random variables with common correlation. 5 for the with common correlation .5 for the one-tailed test. two-tailed test, and critical values for the upper tail of #c standard normal random variables
