Types

#### 8 lectures for CST Part II by Dominic Orchard (previously Andrew Pitts)

 $\langle www.cl.cam.ac.uk/teaching/1415/Types/ \rangle$ 

"One of the most helpful concepts in the whole of programming is the notion of type, used to classify the kinds of object which are manipulated. A significant proportion of programming mistakes are detected by an implementation which does type-checking before it runs any program. Types provide a taxonomy which helps people to think and to communicate about programs."

R. Milner, "Computing Tomorrow" (CUP, 1996), p264

#### Type Systems for Programming Languages

What are 'type systems' and what are they good for?

"A type system is a tractable syntactic method for proving the absence of certain program behaviours by classifying phrases according to the kinds of values they compute"

B. Pierce, 'Types and Programming Languages' (MIT, 2002), p1

Type systems are one of the most important channels by which developments in theoretical computer science get applied in programming language design and software verification.

### Uses of type systems

 Detecting errors via type-checking, either statically (decidable errors detected before programs are executed) or dynamically (typing errors detected during program execution).

e.g.

```
- 42.0 / "foo";
```

```
! Toplevel input:
! 42.0 / "foo"
! ......
! Type clash: expression of type
! string
! cannot have type
! real
```

### Uses of type systems

 Detecting errors via type-checking, either statically (decidable errors detected before programs are executed) or dynamically (typing errors detected during program execution).

e.g.

>>> 42 / "foo"

Traceback (most recent call last):
File "<stdin>", line 1, in <module>
TypeError: unsupported operand type(s) for /: 'int' and 'str'

### Uses of type systems

 Detecting errors via type-checking, either statically (decidable errors detected before programs are executed) or dynamically (typing errors detected during program execution).

・ロト ・ 日 ・ モー・ モー・ つくぐ

- Abstraction and support for structuring large systems.
- Documentation.
- Efficiency.
- Whole-language safety.

## Safety

Informal definitions from the literature.

- 'A safe language is one that protects its own high-level abstractions [no matter what legal program we write in it]'.
- 'A safe language is completely defined by its programmer's manual [rather than which compiler we are using]'.
- 'A safe language may have trapped errors [one that can be handled gracefully], but can't have untrapped errors [ones that cause unpredictable crashes]'.

### Formal type systems

- Constitute the precise, mathematical characterisation of informal type systems (such as occur in the manuals of most typed languages.)
- Basis for type soundness theorems: 'any well-typed program cannot produce run-time errors (of some specified kind)'.
- Can decouple specification of typing aspects of a language from algorithmic concerns: the formal type system can define typing independently of particular implementations of type-checking algorithms.

Notations for the typing relation

'foo has type bar'

ML-style (used in this course):

foo:bar

Haskell-style:

foo::bar

C/Java-style:

bar foo

Typical type system 'judgement'

 $\Gamma \vdash e : \tau$ 

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三三 - のへで

Typical type system 'judgement'

is a relation between typing environments ( $\Gamma$ ), program phrases (e) and type expressions ( $\tau$ ) that we write as

 $\Gamma \vdash e : \tau$ 

and read as: given the assignment of types to free identifiers of e specified by type environment  $\Gamma$ , then e has type  $\tau$ . E.g.

 $f : int list \rightarrow int, b : bool \vdash (if b then f nil else 3) : int$ 

is a valid typing judgement about ML.

Type checking, typeability, and type inference

Suppose given a type system for a programming language with judgements of the form  $\Gamma \vdash e : \tau$ .

- Type-checking problem: given Γ, e, and τ, is Γ ⊢ e : τ derivable in the type system?
- Typeability problem: given  $\Gamma$  and e, is there any  $\tau$  for which  $\Gamma \vdash e : \tau$  is derivable in the type system?

Second problem is usually harder than the first. Solving it usually involves devising a type inference algorithm computing a  $\tau$  for each  $\Gamma$  and e (or failing, if there is none).

A definition for type soundness, progress & preservation

Recall from CST Part IB Semantics:

Progress:

$$\forall s. \ (\Gamma \vdash e : \tau) \land \ (dom(\Gamma) \subseteq dom(s)) \\ \Rightarrow value(e) \lor \exists e', s'. \langle e, s \rangle \rightarrow \langle e', s' \rangle$$

Preservation:

$$(\Gamma \vdash e : \tau) \land (\langle e, s \rangle \rightarrow \langle e', s' \rangle) \Rightarrow \Gamma \vdash e' : \tau$$

#### Course outline

- Introduction. The role of type systems in programming languages. Formalizing type systems. [1 lecture]
- ML polymorphism. ML-style polymorphism. Principal type schemes and type inference. [2 lectures]
- Polymorphic reference types. The pitfalls of combining ML polymorphism with reference types. [1 lecture]
- Polymorphic lambda calculus. Syntax and reduction semantics. Examples of datatypes definable in the polymorphic lambda calculus. Applications. [2 lectures]
- Further topics. The Curry-Howard correspondence (types-as-formulae, terms-as-proofs) as a source of type systems. Dependent types. [2 lectures]

Mid-lecture exercise (4 minutes)

Recall the syntax of the  $\lambda$ -calculus:

$$e ::= v \mid \lambda v.e \mid e_1 e_2$$

(where v ranges over variables).

Define types and a typing relation  $\Gamma \vdash e : \tau$  for  $\lambda$ -calculus terms.

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ 臣 のへで

Simply-typed  $\lambda$ -calculus (monmorphic)

$$(\mathsf{var}) \overline{\Gamma \vdash x : \tau} (x : \tau) \in \mathsf{\Gamma}$$

$$(\mathsf{abs}) \underbrace{ \begin{array}{c} \mathsf{\Gamma}, x : \tau \vdash e : \tau' \\ \overline{\mathsf{\Gamma} \vdash \lambda x.e : \tau \rightarrow \tau'} \end{array} }_{\mathsf{X} \not\in \mathsf{dom}(\mathsf{\Gamma})} x \notin \mathsf{dom}(\mathsf{\Gamma})$$

$$(\mathsf{app}) \underbrace{\begin{array}{ccc} \Gamma \vdash e : \tau \to \tau' & \Gamma \vdash e' : \tau \\ \hline \Gamma \vdash e e' : \tau' \end{array}}_{}$$

recall: "," extends typing context, i.e.  $dom(\Gamma, x : \tau) = dom(\Gamma) \cup \{x : \tau\}$ 

$$(\mathsf{let}) \frac{ \Gamma \vdash e : \tau \quad \Gamma, x : \tau \vdash e' : \tau' }{ \Gamma \vdash \mathsf{let} \, x = e \, \mathsf{in} \, e' : \tau' }$$

Syntactic sugar let x = e in  $e' = (\lambda x.e')e$  (but not in Mini-ML, only in the monomorphic setting).

### Polymorphism = 'has many types'

- Overloading (or 'ad hoc' polymorphism): same symbol denotes operations with unrelated implementations. (E.g. + might mean both integer addition and string concatenation.)
- Subsumption τ<sub>1</sub> <: τ<sub>2</sub>: any M<sub>1</sub> : τ<sub>1</sub> can be used as M<sub>1</sub> : τ<sub>2</sub> without violating safety.
- Parametric polymorphism ('generics'): same expression belongs to a family of structurally related types. (E.g. in SML, length function

fun 
$$length$$
 nil = 0  
|  $length(x :: xs) = 1 + (length xs)$ 

has type  $\tau \text{ list} \rightarrow \text{int}$  for all types  $\tau$ .)

Type variables and type schemes in Mini-ML

To formalise statements like

' length has type  $\tau \ \textit{list} \rightarrow \textit{int}, \ \textit{for all types} \ \tau$  '

it is natural to introduce type variables  $\alpha$  (i.e. variables for which types may be substituted) and write

*length* :  $\forall \alpha (\alpha \text{ list} \rightarrow \text{int}).$ 

 $\forall \alpha (\alpha \text{ list} \rightarrow \text{int}) \text{ is an example of a type scheme.}$ 

Polymorphism of let-bound variables in ML

For example in

let 
$$f = \lambda x(x) \operatorname{in}(f \operatorname{true}) :: (f \operatorname{nil})$$

 $\lambda x(x)$  has type  $\tau \to \tau$  for any type  $\tau$ , and the variable f to which it is bound is used polymorphically:

- in (f true), f has type  $bool \rightarrow bool$
- in (f nil), f has type bool list  $\rightarrow$  bool list

Overall, the expression has type *bool list*.

'Parametric' polymorphism:

```
if f : \forall \alpha (\alpha \rightarrow \alpha),
then (f true) :: (f nil) : bool list.
```

Behaviour is uniform for different type instantiations- does not depend on the type.

Type-dependent behaviour.

### Mini-ML types and type schemes

Types $\tau ::= \alpha$ type variable $\mid bool$ type of booleans $\mid \tau \rightarrow \tau$ function type $\mid \tau \text{ list}$ list type

where  $\alpha$  ranges over a fixed, countably infinite set TyVar.

Type Schemes  $\sigma ::= \forall A(\tau)$ 

where A ranges over finite subsets of the set TyVar.

When  $A = \{\alpha_1, \dots, \alpha_n\}$ , we write  $\forall A(\tau)$  as  $\forall \alpha_1, \dots, \alpha_n(\tau)$ .

# Mini-ML typing judgement

takes the form  $\Gamma \vdash M : \tau$  where

the typing environment Γ is a finite function from variables to type schemes.
 (We write Γ = {x<sub>1</sub> : σ<sub>1</sub>,..., x<sub>n</sub> : σ<sub>n</sub>} to indicate that Γ has domain of definition dom(Γ) = {x<sub>1</sub>,..., x<sub>n</sub>} and maps each x<sub>i</sub> to the type scheme σ<sub>i</sub> for i = 1..n.)

- ► *M* is a Mini-ML expression
- $\tau$  is a Mini-ML type.

### Mini-ML expressions, M

```
variable
::=
     х
                                             boolean values
     true
     false
     if M then M else M
                                             conditional
     \lambda x(M)
                                             function abstraction
     MM
                                             function application
     let x = M in M
                                             local declaration
                                             nil list
     nil
     M::M
                                             list cons
     case M of nil \Rightarrow M \mid x :: x \Rightarrow M
                                             case expression
```

(ロ) (型) (三) (三) (三) (○)

Mini-ML type system, I

### $\Gamma \vdash x : \tau \quad \text{if } (x : \sigma) \in \Gamma \quad \text{and } \sigma \succ \tau \qquad (\text{var} \succ)$

# $\Gamma \vdash B : bool \text{ if } B \in \{\texttt{true}, \texttt{false}\}$ (bool)

$$\frac{\Gamma \vdash M_1 : bool \quad \Gamma \vdash M_2 : \tau \quad \Gamma \vdash M_3 : \tau}{\Gamma \vdash \text{if } M_1 \text{ then } M_2 \text{ else } M_3 : \tau} \quad (\text{if})$$
