1

Roadmap

Starting from a direct implementation of Slang/L3 semantics, we will **DERIVE** a Virtual Machine in a step-by-step manner. The correctness of each step is (more or less) easy to check.

2

LECTURE 7

Interpreter 0, Interpreter 2

1. Interpreter 0 : The high-level “definitional” interpreter
 1. Slang/L3 values represented directly as OCaml values
 2. Recursive interpreter implements a denotational semantics
 3. The interpreter implicitly uses OCaml’s runtime stack
2. Interpreter 2: A high-level stack-oriented machine
 1. Makes the Ocaml runtime stack explicit
 2. Complex values pushed onto stacks
 3. One stack for values and environments
 4. One stack for instructions
 5. Heap used only for references
 6. Instructions have tree-like structure

3

Approaches to Mathematical Semantics

- Axiomatic: Meaning defined through logical specifications of behaviour.
 - Hoare Logic (Part II)
 - Separation Logic
- Operational: Meaning defined in terms of transition relations on states in an abstract machine.
 - Semantics (Part 1B)
- Denotational: Meaning is defined in terms of mathematical objects such as functions.
 - Denotational Semantics (Part II)

4

Most of the code is obvious!

```

let rec interpret (e, env, store) =
  match e with
  | If(e1, e2, e3) ->
    let (v, store') = interpret(e1, env, store) in
      (match v with
       | BOOL true -> interpret(e2, env, store')
       | BOOL false -> interpret(e3, env, store')
       | v -> complain "runtime error. Expecting a boolean!")
  | Pair(e1, e2) ->
    let (v1, store1) = interpret(e1, env, store) in
    let (v2, store2) = interpret(e2, env, store1) in (PAIR(v1, v2), store2)
  | Fst e ->
    (match interpret(e, env, store) with
     | (PAIR (v1, _), store') -> (v1, store')
     | (v, _) -> complain "runtime error. Expecting a pair!")
  | Snd e ->
    (match interpret(e, env, store) with
     | (PAIR (_, v2), store') -> (v2, store')
     | (v, _) -> complain "runtime error. Expecting a pair!")
  | Inl e -> let (v, store') = interpret(e, env, store) in (INL v, store')
  | Inr e -> let (v, store') = interpret(e, env, store) in (INR v, store')
  :
  :
  
```

7

Tricky bits : Slang functions mapped to OCaml functions!

```

let rec interpret (e, env, store) =
  match e with
  :
  :
  | Lambda(x, e) -> (FUN (fun (v, s) -> interpret(e, update(env, (x, v)), s)), store)
  | App(e1, e2) -> (* I chose to evaluate argument first! *)
    let (v2, store1) = interpret(e2, env, store) in
    let (v1, store2) = interpret(e1, env, store1) in
      (match v1 with
       | FUN f -> f (v2, store2)
       | v -> complain "runtime error. Expecting a function!")
  | LetFun(f, (x, body), e) ->
    let new_env =
      update(env, (f, FUN (fun (v, s) -> interpret(body, update(env, (x, v)), s))))
    in interpret(e, new_env, store)
  | LetRecFun(f, (x, body), e) ->
    let rec new_env g = (* a recursive environment!!! *)
      if g = f then FUN (fun (v, s) -> interpret(body, update(new_env, (x, v)), s))
        else env g
    in interpret(e, new_env, store)
  
```

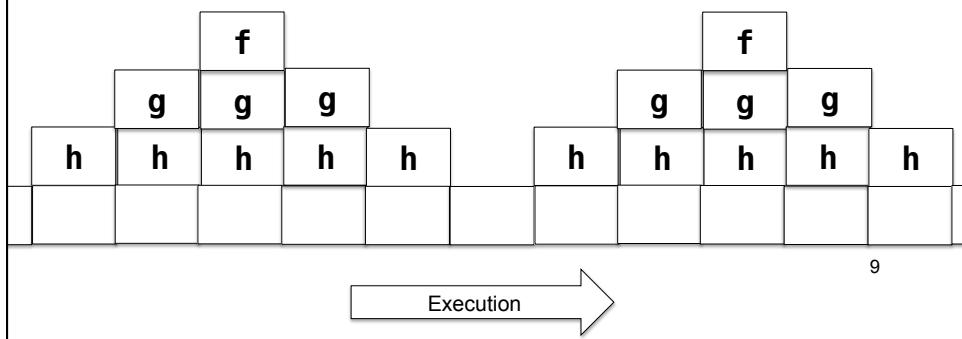

update : env * (var * value) -> env

8

Typical implementation of function calls

```
let fun f (x) = x + 1
    fun g(y) = f(y+2)+2
    fun h(w) = g(w+1)+3
in
  h(h(17))
end
```

The run-time data structure is the call stack containing an activation record for each function invocation.

interpret is implicitly using Ocaml's runtime stack

```
let rec interpret (e, env, store) =
  match e with
  | Integer n      -> (INT n, store)
  | Op(e1, op, e2) ->
    let (v1, store1) = interpret(e1, env, store) in
    let (v2, store2) = interpret(e2, env, store1) in
      (do_oper(op, v1, v2), store2)
  :
  :
```

- Every invocation of interpret is building an activation record on Ocaml's runtime stack.
- We will know define interpreter 2 which makes this stack explicit

Inpterp_2 data types

```

type address
type store = address -> value
and value =
| REF of address
| INT of int
| BOOL of bool
| UNIT
| PAIR of value * value
| INL of value
| INR of value
| FUN of ((value * store)
           -> (value * store)))
type env = Ast.var -> value

```

Interp_0

```

type address = int
type value =
| REF of address
| INT of int
| BOOL of bool
| UNIT
| PAIR of value * value
| INL of value
| INR of value
| CLOSURE of bool *
           closure
and closure = code * env
and instruction =
| PUSH of value
| LOOKUP of var
| UNARY of unary_oper
| OPER of oper
| ASSIGN
| SWAP
| POP
| BIND of var
| FST
| SND
| DEREF
| APPLY
| MK_PAIR
| MK_INL
| MK_INR
| MK_REF
| MK_CLOSURE of code
| MK_REC of var * code
| TEST of code * code
| CASE of code * code
| WHILE of code * code

```

Interp_2

Interp_2.ml : The Abstract Machine

```

and code = instruction list
and binding = var * value
and env = binding list
type env_or_value = EV of env | V of value
type env_value_stack = env_or_value list
type state = code * env_value_stack
val step : state -> state
val driver : state -> value
val compile : expr -> code
val interpret : expr -> value

```

The state is actually
comprised of a
heap --- a global array
of values --- a pair
of the form

(code, evn_value_stack)

12

Interpreter 2: The Abstract Machine

```
type state = code * env_value_stack
val step : state -> state
```

The state transition function.

```
let step = function
(* (code stack,          value/env stack) -> (code stack,  value/env stack) *)
| ((PUSH v)::ds,           evs) -> (ds, (V v)::evs)
| ((POP)::ds,              s :: evs) -> (ds, evs)
| ((SWAP)::ds,             s1 :: s2 :: evs) -> (ds, s2::s1 :: evs)
| ((BIND x)::ds,            (V v)::evs) -> (ds, EV([(x, v)]) :: evs)
| ((LOOKUP x)::ds,          (V v)::evs) -> (ds, V(search(evs, x)) :: evs)
| ((UNARY op)::ds,          (V v1)::(V v2)::evs) -> (ds, V(do_unary(op, v1, v2)) :: evs)
| ((OPER op)::ds,            (V v1)::(V v2)::evs) -> (ds, V(do_oper(op, v1, v2)) :: evs)
| ((MK_PAIR)::ds,            (V v1)::(V v2)::evs) -> (ds, V(PATR(v1, v2)) :: evs)
| ((FST)::ds,                V(PAIR (v, _))::evs) -> (ds, (V v)::evs)
| ((SND)::ds,                V(PAIR (_, v))::evs) -> (ds, (V v)::evs)
| ((MK_INL)::ds,              (V v)::evs) -> (ds, V(INL v)::evs)
| ((MK_INR)::ds,              (V v)::evs) -> (ds, V(INR v)::evs)
| ((CASE (c1, c2))::ds,       V(INL v)::evs) -> (c1 @ ds, (V v)::evs)
| ((CASE (c1, c2))::ds,       V(INR v)::evs) -> (c2 @ ds, (V v)::evs)
| ((TEST(c1, c2))::ds,        V(BOOL true)::evs) -> (c1 @ ds, evs)
| ((TEST(c1, c2))::ds,        V(BOOL false)::evs) -> (c2 @ ds, evs)
| ((ASSIGN :: ds, (V v)::(V (REF a))::evs) -> (heap.(a) <- v; (ds, V(UNIT)::evs))
| ((Deref :: ds, (V v)::(V (REF a))::evs) -> (ds, V(heap.(a))::evs)
| ((MK_REF :: ds, (V v)::evs) -> let a = allocate () in (heap.(a) <- v;
|                                         (ds, V(REF a)::evs))
| ((WHILE(c1, c2))::ds, V(BOOL false)::evs) -> (ds, evs)
| ((WHILE(c1, c2))::ds, V(BOOL true)::evs) -> (c1 @ [WHILE(c1, c2)] @ ds, evs)
| ((MK_CLOSURE c)::ds,         evs) -> (ds, V(mk_fun(c, evs_to_env evs))::evs)
| ((MK_REC(f, c))::ds,        evs) -> (ds, V(mk_rec(f, c, evs_to_env evs))::evs)
| ((APPLY :: ds, V(CLOSURE (_, (c, env)))::(V v)::evs) -> (c @ ds, (V v)::(EV env)::evs)
| state -> complain ("step : bad state = " ^ (string_of_state state) ^ "\n")
```

The driver. Correctness

```
(* val driver : state -> value *)
let rec driver state =
  match state with
  | ([] , [V v]) -> v
  | _                  -> driver (step state)
```

val compile : expr -> code

The idea: if e passes the front-end and
Interp_0.interpret e = v
then
driver (compile e, []) = v'
where v' (somehow) represents v.

In other words,
evaluating
compile e
should leave the
value of e on top
of the stack

14

Implement inter_0 in interp_2

```

let rec interpret (e, env, store) =
  match e with
  | Pair(e1, e2) ->
    let (v1, store1) = interpret(e1, env, store) in
    let (v2, store2) = interpret(e2, env, store1) in (PAIR(v1, v2), store2)
  | Fst e ->
    (match interpret(e, env, store) with
     | (PAIR (v1, _), store') -> (v1, store')
     | (v, _) -> complain "runtime error. Expecting a pair!")
  :
let step = function
  | (MK_PAIR :: ds, (V v2) :: (V v1) :: evs) -> (ds, V(PAIR(v1, v2)) :: evs)
  | (FST :: ds, V(PAIR (v, _)) :: evs) -> (ds, (V v) :: evs)
  :
let rec compile = function
  | Pair(e1, e2) -> (compile e1) @ (compile e2) @ [MK_PAIR]
  | Fst e -> (compile e) @ [FST]
  :

```

interp_0.ml

15

Implement inter_0 in interp_2

```

let rec interpret (e, env, store) =
  match e with
  | If(e1, e2, e3) ->
    let (v, store') = interpret(e1, env, store) in
    (match v with
     | BOOL true -> interpret(e2, env, store')
     | BOOL false -> interpret(e3, env, store')
     | v -> complain "runtime error. Expecting a boolean!")
  :
let step = function
  | ((TEST(c1, c2)) :: ds, V(BOOL true) :: evs) -> (c1 @ ds, evs)
  | ((TEST(c1, c2)) :: ds, V(BOOL false) :: evs) -> (c2 @ ds, evs)
  :
let rec compile = function
  | If(e1, e2, e3) -> (compile e1) @ [TEST(compile e2, compile e3)]
  :

```

interp_2.ml

16

Tricky bits again!

<pre> let rec interpret (e, env, store) = match e with Lambda(x, e) -> (FUN (fun v, s) -> interpret(e, update(env, (x, v)), s)), store) App(e1, e2) -> (* I chose to evaluate argument first! *) let (v2, store1) = interpret(e2, env, store) in let (v1, store2) = interpret(e1, env, store1) in (match v1 with FUN f -> f (v2, store2) v -> complain "runtime error. Expecting a function!") : </pre>	interp_0.ml
<pre> let step = function (POP :: ds, s :: evs) -> (ds, evs) (SWAP :: ds, s1 :: s2 :: evs) -> (ds, s2 :: s1 :: evs) ((BIND x) :: ds, (V v) :: evs) -> (ds, EV([(x, v)]) :: evs) ((MK_CLOSURE c) :: ds, evs) -> (ds, V(mk_fun(c, evs_to_env evs)) :: evs) (APPLY :: ds, V(CLOSURE (_, (c, env))) :: (V v) :: evs) -> (c @ ds, (V v) :: (EV env) :: evs) let rec compile = function Lambda(x, e) -> [MK_CLOSURE((BIND x) :: (compile e) @ [SWAP; POP])] App(e1, e2) -> (compile e2) @ (compile e1) @ [APPLY; SWAP; POP] : </pre>	interp_2.ml

17

Example : Compiled code for rev_pair.slang

<pre> let rev_pair (p : int * int) : int * int = (snd p, fst p) in rev_pair (21, 17) end </pre>

<pre> MK_CLOSURE([BIND p; LOOKUP p; SND; LOOKUP p; FST; MK_PAIR; SWAP; POP]); BIND rev; PUSH 21; PUSH 17; MK_PAIR; LOOKUP rev; APPLY; SWAP; POP; SWAP; POP </pre>	DEMO TIME!!!
---	---------------------

18

LECTURE 8

Derive Interpreter 3

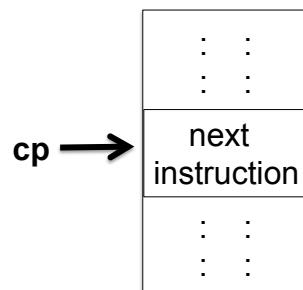

1. “Flatten” code into linear array
2. Add “code pointer” (cp) to machine state
3. New instructions : LABEL, GOTO, RETURN
4. “Compile away” conditionals and while loops

19

Linearise code

Interpreter 2 copies code on the code stack.

We want to introduce one global array of instructions indexed by a code pointer (**cp**). At runtime the **cp** points at the next instruction to be executed.

This will require two new instructions:

LABEL L : Associate label L with this location in the code array

GOTO L : Set the **cp** to the code address associated with L

20

Compile conditionals, loops

If(e1, e2, e3)

code for e1

TEST k

code for e2

GOTO m

k: code for e3

m:

While(e1, e2)

m: code for e1

TEST k

code for e2

GOTO m

k:

21

If ? = 0 Then 17 else 21 end

interp_2

```
PUSH UNIT;
UNARY READ;
PUSH 0;
OPER EQI;
TEST(
    [PUSH 17],
    [PUSH 17]
)
```

interp_3

```
PUSH UNIT;
UNARY READ;
PUSH 0;
OPER EQI;
TEST L0;
PUSH 17;
GOTO L1;
LABEL L0;
PUSH 21;
LABEL L1;
HALT
```

interp_3 (loaded)

```
0: PUSH UNIT;
1: UNARY READ;
2: PUSH 0;
3: OPER EQI;
4: TEST LO = 7;
5: PUSH 17;
6: GOTO L1 = 9;
7: LABEL LO;
8: PUSH 21;
9: LABEL L1;
10: HALT
```

Symbolic code locations

Numeric code locations

22

11

Implement interp_2 in interp_3

```
let step = function
| ((TEST(c1, c2)) :: ds, V(BOOL true) :: evs) -> (c1 @ ds, evs)
| ((TEST(c1, c2)) :: ds, V(BOOL false) :: evs) -> (c2 @ ds, evs)
:
```

interp_2.ml

```
let step (cp, evs) =
match (get_instruction cp, evs) with
| (TEST (_), Some _) , V(BOOL true) :: evs) -> (cp + 1, evs)
| (TEST (_), Some i), V(BOOL false) :: evs) -> (i, evs)
| (LABEL l, evs) -> (cp + 1, evs)
| (GOTO (_, Some i), evs) -> (i, evs)
:
```

Interp_3.ml

Code locations are represented as

("L", None) : not yet loaded (assigned numeric address)

("L", Some i) : label "L" has been assigned numeric address i

Tricky bits again!

```
let step = function
| (POP :: ds, s :: evs) -> (ds, evs)
| (SWAP :: ds, s1 :: s2 :: evs) -> (ds, s2 :: s1 :: evs)
| ((BIND x) :: ds, (V v) :: evs) -> (ds, EV([(x, v)]) :: evs)
| ((MK_CLOSURE c) :: ds, evs) -> (ds, V(mk_fun(c, evs_to_env evs)) :: evs)
| (APPLY :: ds, V(CLOSURE (_, (c, env)))) :: (V v) :: evs)
-> (c @ ds, (V v) :: (EV env) :: evs)
```

interp_2.ml

```
let step (cp, evs) =
match (get_instruction cp, evs) with
| (POP, s :: evs) -> (cp + 1, evs)
| (SWAP, s1 :: s2 :: evs) -> (cp + 1, s2 :: s1 :: evs)
| (BIND x, (V v) :: evs) -> (cp + 1, EV([(x, v)]) :: evs)
| (MK_CLOSURE loc, evs) -> (cp + 1,
V(CLOSURE(loc, evs_to_env evs)) :: evs)
| (RETURN, (V v) :: _ :: (RA i) :: evs) -> (i, (V v) :: evs)
| (APPLY, V(CLOSURE ((_, Some i), env)) :: (V v) :: evs)
-> (i, (V v) :: (EV env) :: (RA (cp + 1)) :: evs)
```

interp_3.ml

Note that in interp_2 the body of a closure is consumed from the code stack. But in interp_3 we need to save the return address on the stack (here i is the location of the closure's code).

Tricky bits again!	
<pre> let rec compile = function Lambda(x, e) -> [MK_CLOSURE((BIND x) :: (compile e) @ [SWAP; POP])] App(e1, e2) -> (compile e2) @ (compile e1) @ [APPLY; SWAP; POP] let rec comp = function App(e1, e2) -> let (defs1, c1) = comp e1 in let (defs2, c2) = comp e2 in (defs1 @ defs2, c2 @ c1 @ [APPLY]) Lambda(x, e) -> let (defs, c) = comp e in let f = new_label () in let def = [LABEL f; BIND x] @ c @ [SWAP; POP; RETURN] in (def @ defs, [MK_CLOSURE((f, None))]) let compile e = let (defs, c) = comp e in c (* body of program *) @ [HALT] (* stop the interpreter *) @ defs (* function definitions *) </pre>	interp_2.ml Interp_3.ml Interp_3.ml
	25

Interpreter 3 (very similar to interpreter 2)	
<pre> let step (cp, evs) = match (get_instruction cp, evs) with (PUSH v, s1 :: s2 :: evs) -> (cp + 1, (V v) :: evs) (POP, s :: evs) -> (cp + 1, evs) (SWAP, (V v) :: evs) -> (cp + 1, s2 :: s1 :: evs) (BIND x, (V v) :: evs) -> (cp + 1, EV([(x, v)])) :: evs) (LOOKUP x, (V v) :: evs) -> (cp + 1, V(search(evs, x))) :: evs) (UNARY op, (V v1) :: evs) -> (cp + 1, V(do_unary(op, v1))) :: evs) (OPER op, (V v1), (V v2) :: evs) -> (cp + 1, V(do_oper(op, v1, v2))) :: evs) (MK_PAIR, (V v1), (V v2) :: evs) -> (cp + 1, V(PAIR(v1, v2))) :: evs) (FST, V(PAIR (v, _)) :: evs) -> (cp + 1, (V v) :: evs) (SND, V(PAIR (_, v)) :: evs) -> (cp + 1, (V v) :: evs) (MK_INL, (V v) :: evs) -> (cp + 1, V(INL v)) :: evs) (MK_INR, (V v) :: evs) -> (cp + 1, V(INR v)) :: evs) (CASE (i, Some j), V(INL v)::evs) -> (cp + 1, (V v) :: evs) (CASE (i, Some j), V(INR v)::evs) -> (i, (V v) :: evs) (TEST (i, Some j), V(BOOL true) :: evs) -> (cp + 1, evs) (TEST (i, Some j), V(BOOL false) :: evs) -> (i, evs) (ASSIGN, (V v) :: (V (REF a)) :: evs) -> (heap.(a) <- v; (cp + 1, V(UNIT) :: evs)) (Deref, (V (REF a)) :: evs) -> (cp + 1, V(heap.(a)) :: evs) (MK_REF, (V v) :: evs) -> let a = new_address () in (heap.(a) <- v; (cp + 1, V(REF a)) :: evs) (MK_CLOSURE loc, evs) -> (cp + 1, V(CLOSURE(loc, evs_to_env evs))) :: evs) (APPLY, V(CLOSURE ((_, Some i), env)) :: (V v) :: evs) -> (i, (V v) :: (EV env) :: (RA (cp + 1)) :: evs) (* new instructions *) (RETURN, (V v) :: _ :: (RA i) :: evs) -> (i, (V v) :: evs) (LABEL i, evs) -> (cp + 1, evs) (HALT, evs) -> (cp, evs) (GOTO (i, Some j), evs) -> (i, evs) _ -> complain ("step : bad state = " ^ (string_of_state (cp, evs)) ^ "\n") </pre>	26

Some observations

- A very clean machine!
- But it still has a **very** inefficient treatment of environments.
- Also, pushing complex values on the stack is not what most virtual machines do. In fact, we are still using OCaml's runtime memory management to manipulate complex values.

27

Example : Compiled code for rev_pair.slang

```
let rev_pair (p : int * int) : int * int = (snd p, fst p)
in
  rev_pair (21, 17)
end
```

```
MK_CLOSURE(
  [BIND p; LOOKUP p; SND;
   LOOKUP p; FST; MK_PAIR;
   SWAP; POP]);
BIND rev;
PUSH 21;
PUSH 17;
MK_PAIR;
LOOKUP rev_pair;
APPLY;
SWAP;
POP;
SWAP;
POP
```

Interp_2

```
MK_CLOSURE(rev_pair)
BIND rev
PUSH 21
PUSH 17
MK_PAIR
LOOKUP rev_pair
APPLY
SWAP
POP
HALT
```

Interp_3

```
LABEL rev_pair
BIND p
LOOKUP p
SND
LOOKUP p
FST
MK_PAIR
SWAP
POP
RETURN
```

DEMO TIME!!!

LECTURES 9, 10

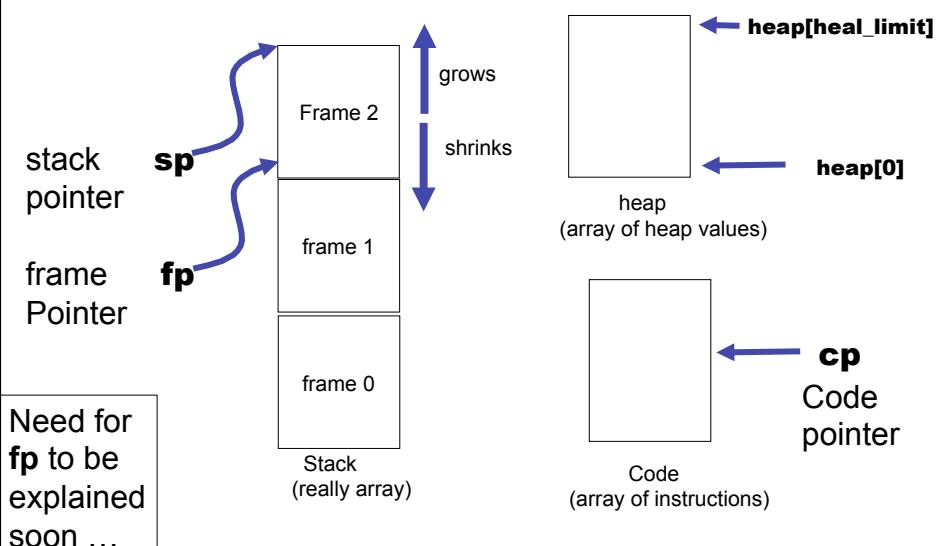

Deriving The Jargon VM

(interpreter 4)

1. **First change:** Introduce an addressable stack.
2. Replace variable lookup by a (relative) location on the stack or heap determined at compile time.
3. Relative to what? A **frame pointer (fp)** pointing into the stack is needed to keep track of the current **activation record**.
4. **Second change:** Optimise the representation of closures so that they contain only the values associated with the free variables of the closure.
5. **Third change:** Restrict values on stack to be simple (ints, bools, heap addresses, etc). Complex data is moved to the heap, leaving pointer into the heap on the stack.
6. How might things look different in a language without first-class functions? In a language with multiple arguments to function calls?

29

Jargon Virtual Machine

30

The stack in interpreter 3

A stack
in interpreter 3

(1, (2, 17))
Inl(inr(99))
:
:
:

Stack elements in interpreter 3
are not of fixed size.

Virtual machines (JVM, etc)
typically restrict stack elements
to be of a fixed size

We need to shift data from the
high-level stack of interpreter 3
to a lower-level stack with
fixed size elements.

Solution : put the data in the heap.
Place pointers to the heap on
the stack.

"All problems in computer
science can be solved by
another level of indirection,
except of course for the
problem of too many
indirections."

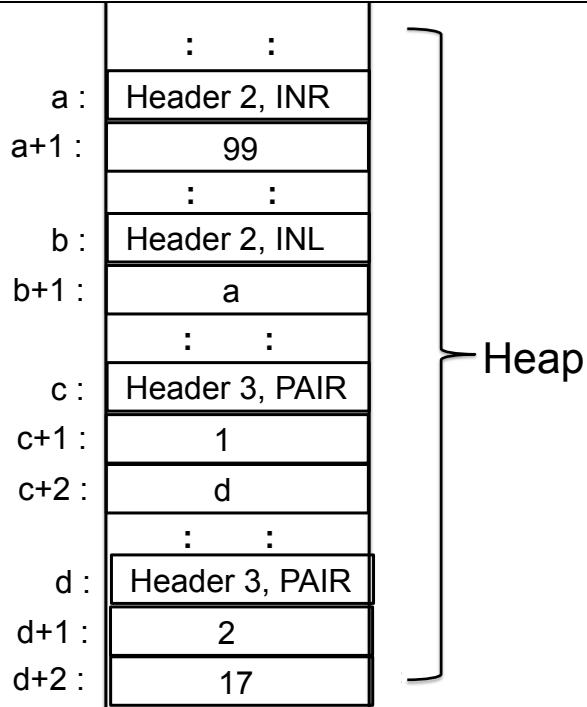

--- David Wheeler

MK_INR (MK_INL is similar)

In interpreter 3

$(\text{MK_INR}, \quad (\text{V } v) :: \text{evs}) \rightarrow (\text{cp} + 1, \text{V}(\text{INR}(v)) :: \text{evs})$

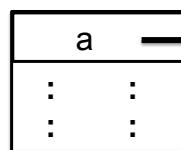

Jargon VM

The stack
before

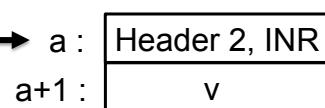

MK_INR

The stack
after

Newly allocated
locations in
the heap

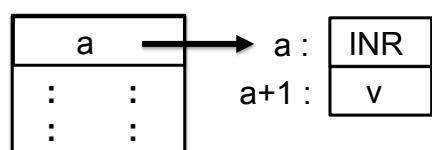

Note: The header types are not really required. We could instead add an extra field here (for example, 0 or 1). However, header types aid in understanding the code and traces of runtime execution.

CASE (TEST is similar)

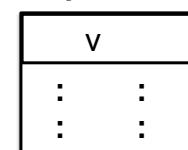

$(\text{CASE } (_), \text{Some } _), \text{ V}(\text{INL } v)::\text{evs}) \rightarrow (\text{cp} + 1, (\text{V } v) :: \text{evs})$
 $(\text{CASE } (_), \text{Some } i), \text{ V}(\text{INR } v)::\text{evs}) \rightarrow (i, \quad (\text{V } v) :: \text{evs})$

cp = t

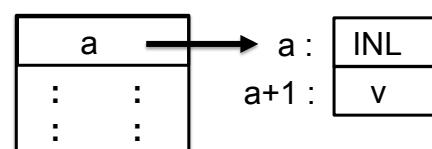

CASE i

cp = i

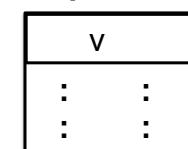

cp = t

CASE i

cp = t + 1

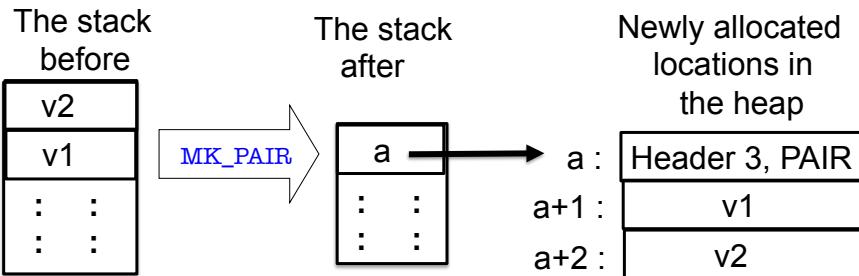

MK_PAIR

In interpreter 3:

(**MK_PAIR**, (**V** v2) :: (**V** v1) :: evs) -> (cp + 1, **V(PAIR(v1, v2)) :: evs**)

In Jargon VM:

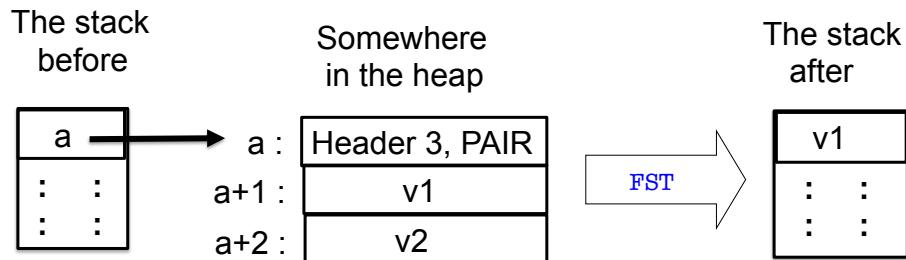

37

FST (similar for SND)

In interpreter 3:

(**FST**, **V (PAIR(v1, v2)) :: evs**) -> (cp + 1, **v1 :: evs**)

In Jargon VM:

Note that v1 could be a simple value (int or bool), or another heap address.

38

These require more care ...

In interpreter 3:

```
let step (cp, evs) =
  match (get_instruction cp, evs) with
  | (MK_CLOSURE loc, evs)
    -> (cp + 1, V(CLOSURE)(loc, evs_to_env evs)) :: evs)

  | (APPLY, V(CLOSURE) (_, Some i), env) :: (V v) :: evs)
    -> (i, (V v) :: (EV env) :: (RA (cp + 1)) :: evs)

  | (RETURN, (V v) :: _ :: (RA i) :: evs)
    -> (i, (V v) :: evs)
```

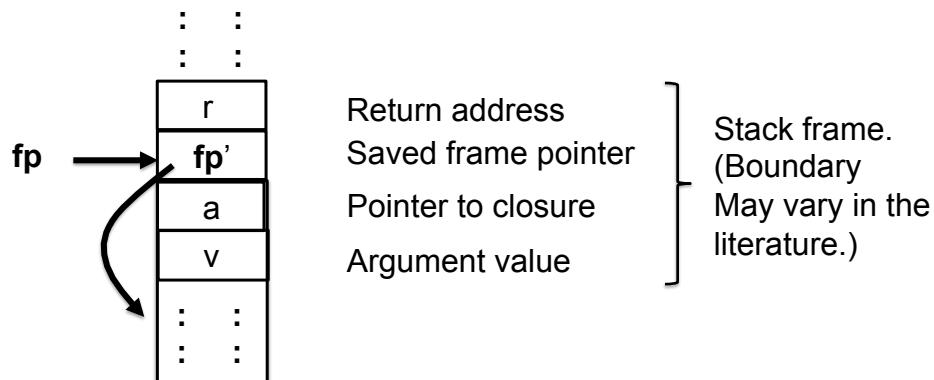

MK_CLOSURE(c, n)

c = code location of start of instructions for closure,
n = number of free variables in the body of closure.

Put values associated with free variables on stack,
then construct the closure on the heap

A stack frame

41

APPLY

Interpreter 3:

(APPLY, V(CLOSURE ((_, Some i), env)) :: (V v) :: evs)
 $\rightarrow (i, (V v) :: (\text{EV env}) :: (\text{RA} (cp + 1)) :: evs)$

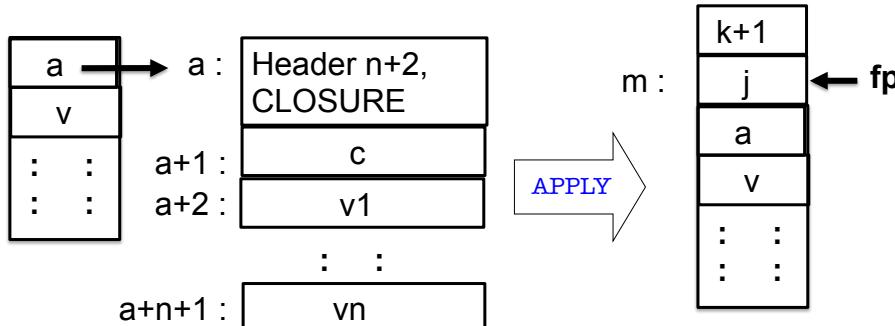

Jargon VM:

BEFORE

$cp = k$
 $fp = j$

AFTER

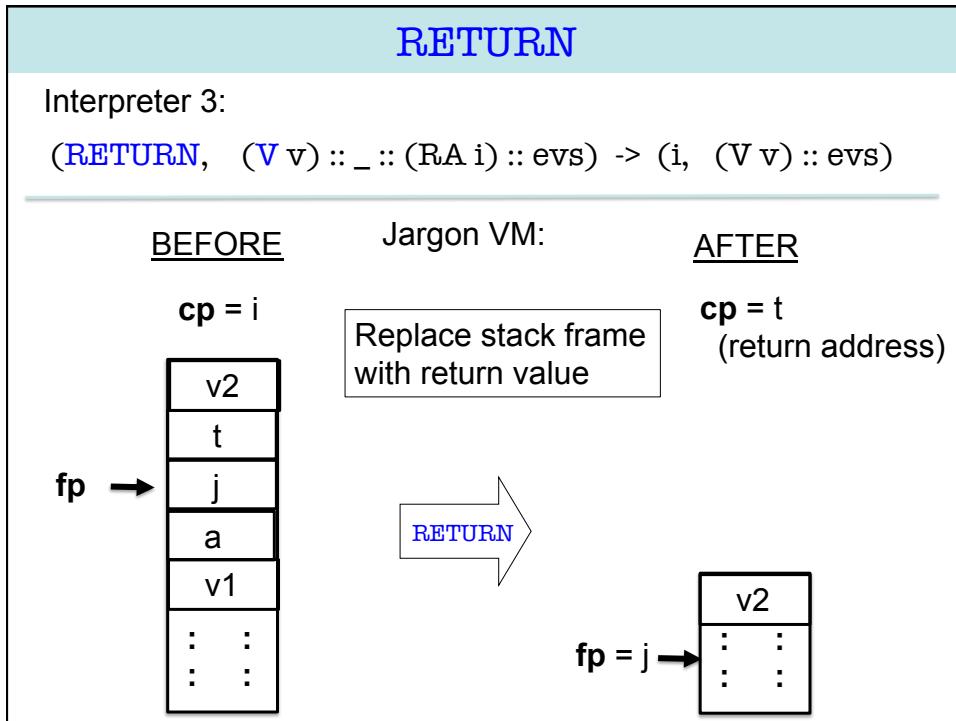

$cp = i$
 $fp = m$

RETURN

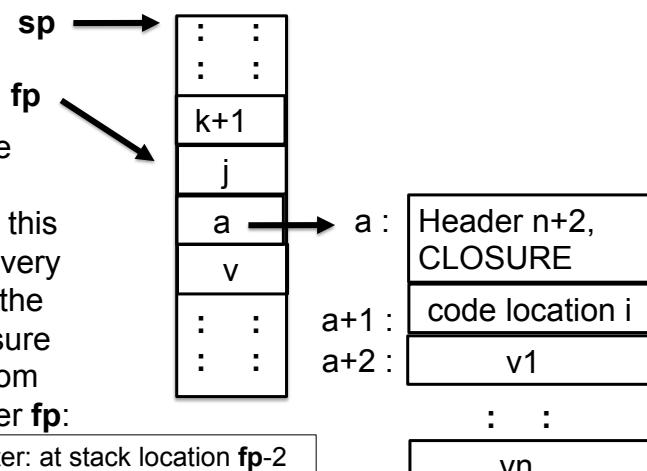

Interpreter 3:

`(RETURN, (V v) :: _ :: (RA i) :: evs) -> (i, (V v) :: evs)`

Finding a variable's value at runtime

Suppose we are executing code associated with this closure. Then every free variable in the body of the closure can be found from the frame pointer **fp**:

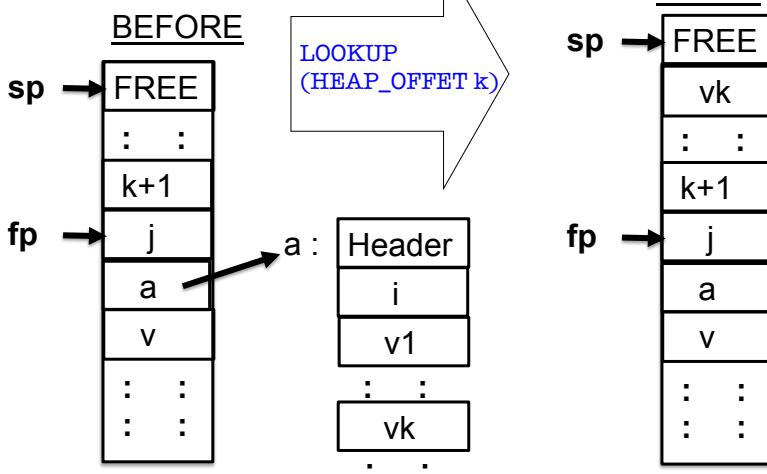

- Formal parameter: at stack location **fp-2**
- Other free variables :
 - Follow heap pointer found at **fp -1**
 - Each free variable can be associated with a fixed offset from this heap address

LOOKUP (HEAP_OFFSET k)

Interpreter 3:

(**LOOKUP** x, evs) -> (cp + 1, **V**(search(evs, x)) :: evs)

Jargon VM:

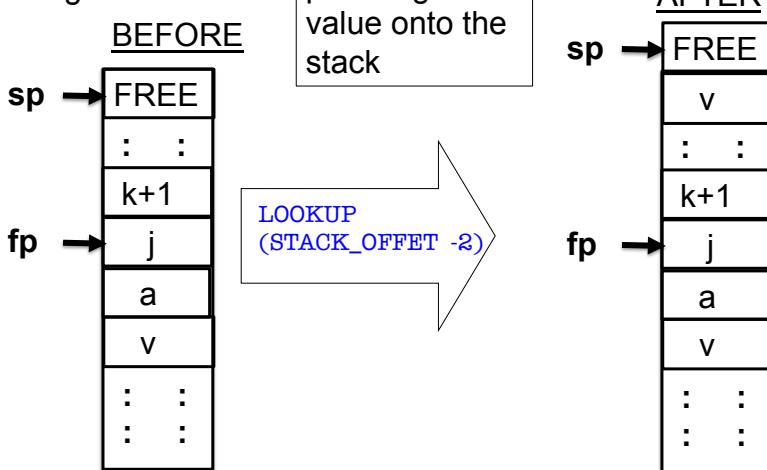

LOOKUP (STACK_OFFSET -2)

Interpreter 3:

(**LOOKUP** x, evs) -> (cp + 1, **V**(search(evs, x)) :: evs)

Jargon VM:

Oh, one problem

```
let rec comp = function
:
| LetFun(f, (x, e1), e2) ->
    let (defs1, c1) = comp e1 in
    let (defs2, c2) = comp e2 in
    let def = [LABEL f; BIND x] @ c1 @ [SWAP; POP; RETURN] in
        (def @ defs1 @ defs2,
         [MK_CLOSURE((f, None)); BIND f] @ c2 @ [SWAP; POP])
:

```

interpreter 3

Problem: Code c_2 can be anything --- how are we going to find the closure for f when we need it? It has to be a fixed offset from a frame pointer --- we no longer scan the stack for bindings!

```
let rec comp vmap = function
:
| LetFun(f, (x, e1), e2) -> comp vmap (App(Lambda(f, e2), Lambda(x, e1)))
:
```

Solution in Jargon VM

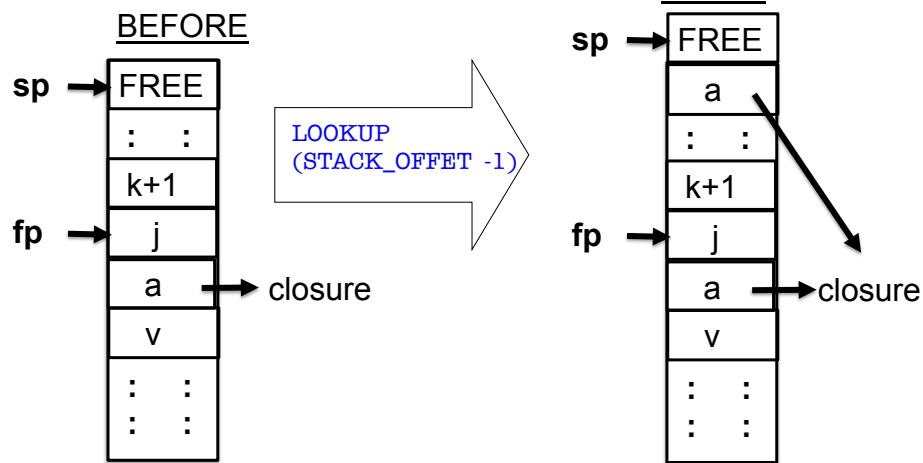

Similar trick for [LetRecFun](#)

47

LOOKUP (STACK_OFFSET -1)

For recursive function calls,
push current closure on to the stack.

Jargon VM:

Example : Compiled code for rev_pair.slang

```
let rev_pair (p : int * int) : int * int = (snd p, fst p)
in
  rev_pair (21, 17)
end
```

After the front-end, compile treats this as follows.

```
App(
  Lambda(
    "rev_pair",
    App(Var "rev_pair", Pair(Integer 21, Integer 17))),
  Lambda("p", Pair(Snd(Var "p"), Fst(Var "p"))))
```

49

Example : Compiled code for rev_pair.slang

```
App(
  Lambda("rev_pair",
    App(Var "rev_pair", Pair(Integer 21, Integer 17))),
  Lambda("p", Pair(Snd(Var "p"), Fst(Var "p"))))
```

MK_CLOSURE(L1, 0)	-- Make closure for second lambda
MK_CLOSURE(L0, 0)	-- Make closure for first lambda
APPLY	-- do application
HALT	-- the end!
L0 :	PUSH STACK_INT 21 PUSH STACK_INT 17 MK_PAIR LOOKUP STACK_LOCATION -2 APPLY RETURN
	-- code for first lambda, push 21 -- push 17 -- make the pair on the heap -- push closure for second lambda on stack -- apply first lambda -- return from first lambda
L1 :	LOOKUP STACK_LOCATION -2 SND LOOKUP STACK_LOCATION -2 FST MK_PAIR RETURN
	-- code for second lambda, push arg on stack -- extract second part of pair -- push arg on stack again -- extract first part of pair -- construct a new pair -- return from second lambda

50

Example : trace of rev_pair.slang execution

```

Installed Code =
0: MK_CLOSURE(L1 = 11, O)
1: MK_CLOSURE(LO = 4, O)
2: APPLY
3: HALT

1 -> HEAP_CI 11
2 -> HEAP_HEADER(2, HT_CLOSURE)
3 -> HEAP_CI 4
4 -> HEAP_HEADER(3, HT_PAIR)
5 -> HEAP_INT 21
6 -> HEAP_INT 17
7 -> HEAP_HEADER(3, HT_PAIR)
8 -> HEAP_INT 17
9 -> HEAP_INT 21

Jargon VM :
output> (17, 21)

```

Example : closure_add.slang

```

let f(y : int) : int -> int = let g(x : int) : int = y + x in g end
in let add21 : int -> int = f(21)
   in let add17 : int -> int = f(17)
      in add17(3) + add21(10)
         end
      end
end
end

```

Note : we really do need closures on the heap here — the values 21 and 17 do not exist on the stack at this point in the execution.

After the front-end, this becomes represented as follows.

```

App(Lambda(f, App(Lambda(add21,
                           App(Lambda(add17,
                                         Op(App(Var(add17), Integer(3)),
                                             ADD,
                                             App(Var(add21), Integer(10)))),
                                         App(Var(f), Integer(17))),
                                         App(Var(f), Integer(21)))),
                           Lambda(y, App(Lambda(g, Var(g)), Lambda(x, Op(Var(y), ADD, Var(x)))))))

```

53

```

Jargon VM code

Remarks

1. The semantic GAP between a Slang/L3 program and a low-level translation (say x86/Unix) has been significantly reduced.
2. Implementing the Jargon VM at a lower-level of abstraction (in C?, JVM bytecodes? X86/Unix? ...) looks like a relatively easy programming problem.
3. However, using a lower-level implementation (say x86, exploiting fast registers) to generate very efficient code is not so easy. See Part II Optimising Compilers.

Verification of compilers is an active area of research.
See CompCert, CakeML, and DeepSpec.

What about languages other than Slang/L3?

- Many textbooks on compilers treat only languages with first-order functions --- that is, functions cannot be passed as an argument or returned as a result. In this case, we can avoid allocating environments on the heap since all values associated with free variables will be somewhere on the stack!
- But how do we find these values? We optimise stack search by following a chain of **static links**. Static links are added to every stack frame and point to the stack frame of the last invocation of the defining function.
- One other thing: most languages take multiple arguments for a function/procedure call.

Terminology: Caller and Callee

```
fun f (x, y) = e1  
...  
fun g(w, v) =  
    w + f(v, v)
```

For this invocation of
the function f, we say
that g is the caller
while f is the callee

Recursive functions can play
both roles at the same time ...

Nesting depth

Pseudo-code

```
fun b(z) = e  
  
fun g(x1) =  
  fun h(x2) =  
    fun f(x3) = e3(x1, x2, x3, b, g h, f)  
    in  
      e2(x1, x2, b, g, h, f)  
    end  
  in  
    e1(x1, b, g, h)  
  end  
...  
b(g(17))  
...
```

59

Nesting depth

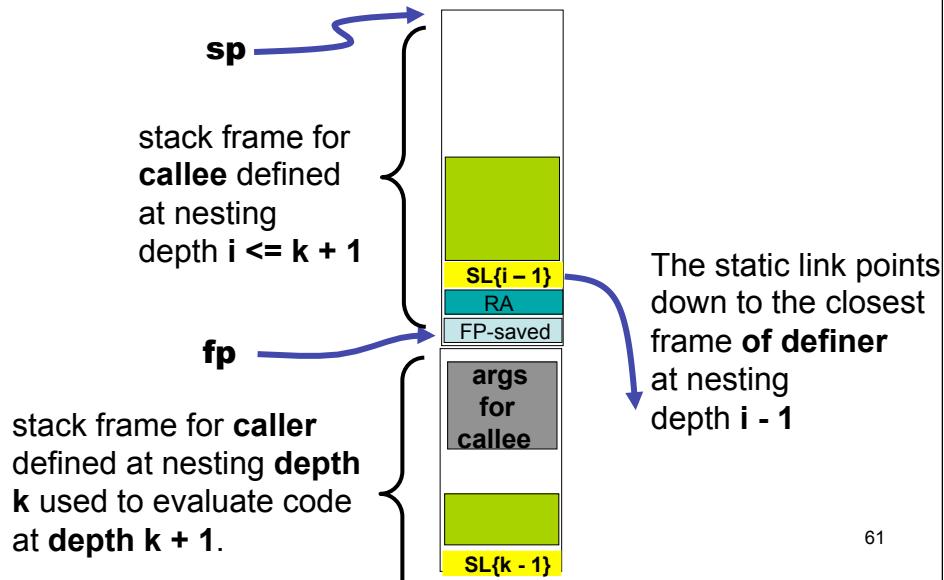

code in big box is at nesting depth k

```
fun b(z) = e  nesting depth k + 1  
  
fun g(x1) =  
  fun h(x2) =  
    fun f(x3) = e3(x1, x2, x3, b, g h, f)  nesting depth k + 3  
    in  
      e2(x1, x2, b, g, h, f)  
    end  nesting depth k + 2  
  in  
    e1(x1, b, g, h)  
  end  nesting depth k + 1  
...  
b(g(17))  
...
```

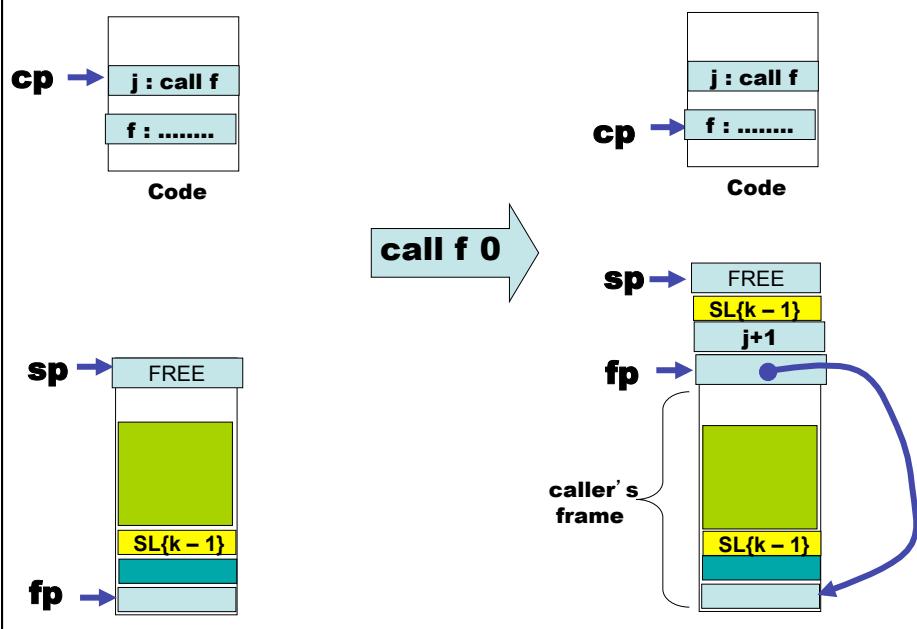

60

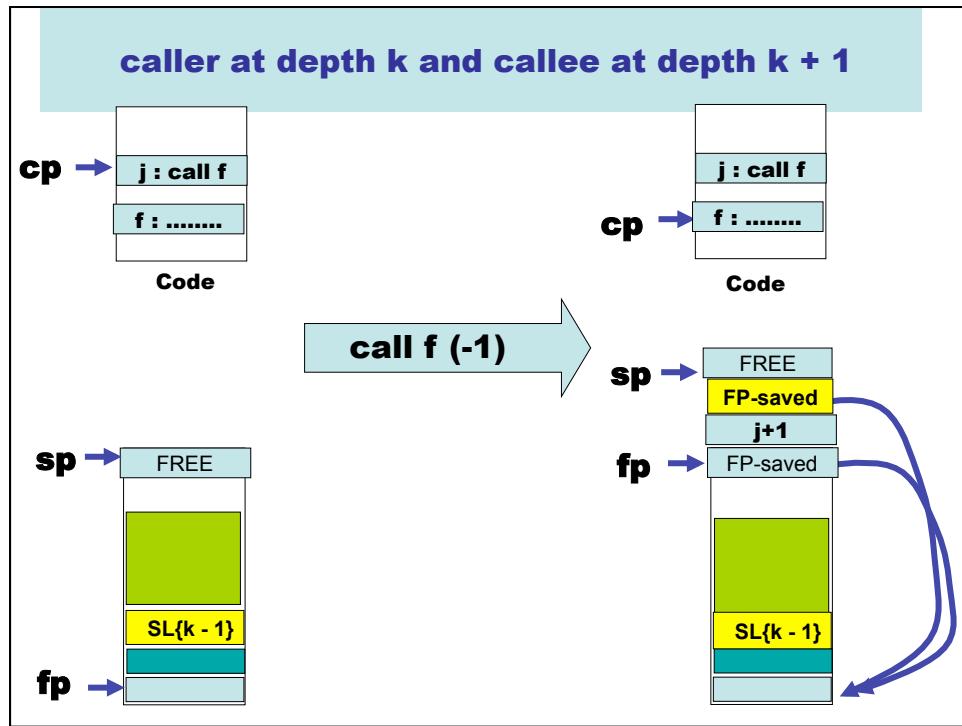

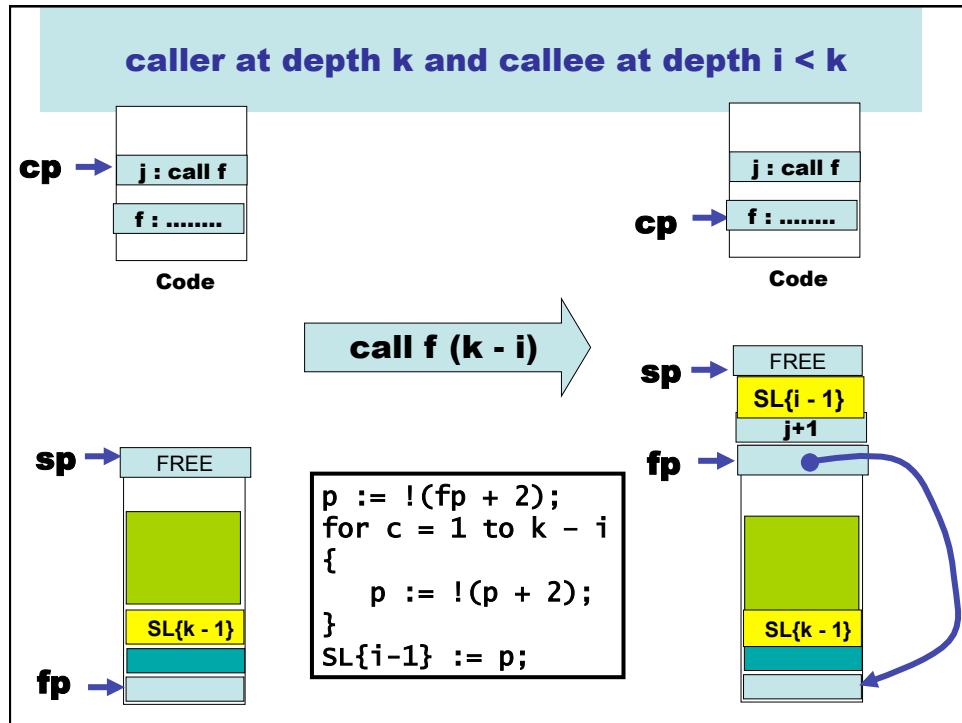

Function g is the **definer** of h. Functions g and b must share a definer defined at depth k-1

Stack with static links and variable number of arguments

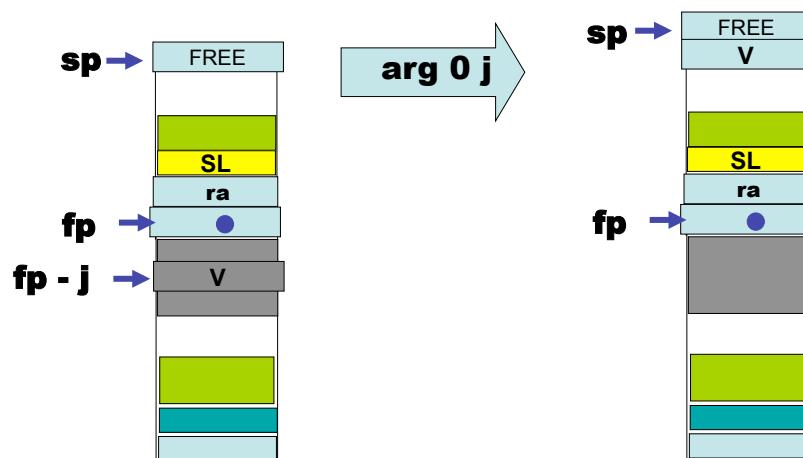

caller and callee at same nesting depth k

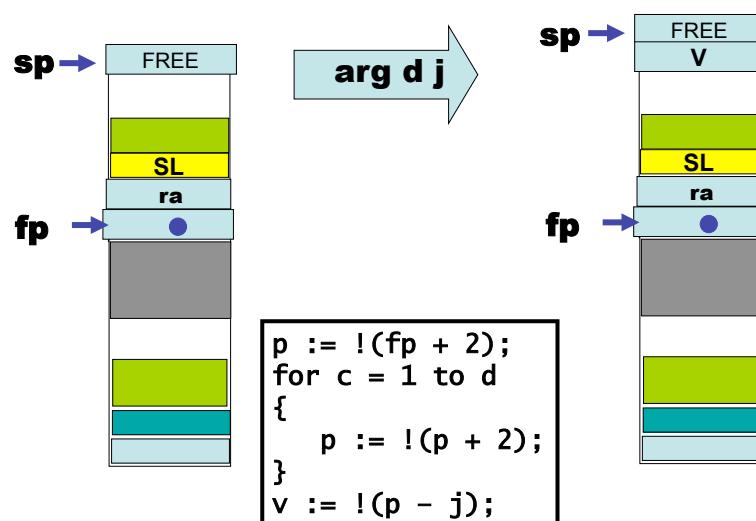

Access to argument values at static distance 0

Access to argument values at static distance d, $0 < d$

LECTUREs 11, 12 What about Interpreter 1?

- Evaluation using a stack
- Recursion using a stack
- Tail recursion elimination: from recursion to iteration
- Continuation Passing Style (CPS) : transform any recursive function to a tail-recursive function
- “Defunctionalisation” (DFC) : replace higher-order functions with a data structure
- Putting it all together:
 - Derive the Fibonacci Machine
 - Derive the Expression Machine, and “compiler”!
- This provides a roadmap for the interp_0 → interp_1 → interp_2 derivations.

67

Example of tail-recursion : gcd

```
(* gcd : int * int -> int *)
let rec gcd(m, n) =
  if m = n
  then m
  else if m < n
  then gcd(m, n - m)
  else gcd(m - n, n)
```

Compared to fib, this function uses recursion in a different way. It is **tail-recursive**. If implemented with a stack, then the “call stack” (at least with respect to gcd) will simply grow and then shrink. No “ups and downs” in between.

	gcd(1,1)	___ 1 ___					
	gcd(1,2)	gcd(1,2)	gcd(1,2)	___ 1 ___			
	gcd(3,2)	gcd(3,2)	gcd(3,2)	gcd(3,2)	gcd(3,2)	___ 1 ___	
gcd(3,5)	gcd(3,5)	gcd(3,5)	gcd(3,5)	gcd(3,5)	gcd(3,5)	gcd(3,5)	___ 1 ___

Tail-recursive code can be replaced by iterative code that does not require a “call stack” (constant space)

68

gcd_iter : gcd without recursion!

```
(* gcd : int * int -> int *)
let rec gcd(m, n) =
  if m = n
  then m
  else if m < n
  then gcd(m, n - m)
  else gcd(m - n, n)
```

Here we have illustrated tail-recursion elimination as a source-to-source transformation. However, the OCaml compiler will do something similar to a lower-level intermediate representation. Upshot : we will consider all tail-recursive OCaml functions as representing iterative programs.

```
(* gcd_iter : int * int -> int *)
let gcd_iter (m, n) =
  let rm = ref m
  in let rn = ref n
  in let result = ref 0
  in let not_done = ref true
  in let _ =
    while !not_done
    do
      if !rm = !rn
      then (not_done := false;
             result := !rm)
      else if !rm < !rn
            then rn := !rn - !rm
            else rm := !rm - !rn
    done
  in !result
```

Familiar examples : fold_left, fold_right

From ocaml-4.01.0/stdlib/list.ml :

```
(* fold_left : ('a -> 'b -> 'a) -> 'a -> 'b list -> 'a

  fold_left f a [b1; ...; bn]] = f(...(f(f a b1) b2) ...) bn
*)
let rec fold_left f a l =
  match l with
  | []      -> a
  | b :: rest -> fold_left f (f a b) rest

(* fold_right : ('a -> 'b -> 'b) -> 'a list -> 'b -> 'b

  fold_right f [a1; ...; an] b = f a1 (f a2 (... (f an b) ...))
*)
let rec fold_right f l b =
  match l with
  | []      -> b
  | a :: rest -> f a (fold_right f rest b)
```

This is tail recursive

This is NOT tail recursive

70

Question: can we transform any recursive function into a tail recursive function?

The answer is YES!

- We add an extra argument, called a *continuation*, that represents “the rest of the computation”
- This is called the Continuation Passing Style (CPS) transformation.
- We will then “defunctionalize” (DFC) these continuations and represent them with a stack.
- Finally, we obtain a tail recursive function that carries its own stack as an extra argument!

We will apply this kind of transformation to the code of interpreter 0 as the first steps towards deriving interpreter 1.

71

(CPS) transformation of fib

```
(* fib : int -> int *)
let rec fib m =
  if m = 0
  then 1
  else if m = 1
    then 1
    else fib(m - 1) + fib (m - 2)

(* fib_cps : int * (int -> int) -> int *)
let rec fib_cps (m, cnt) =
  if m = 0
  then cnt 1
  else if m = 1
    then cnt 1
    else fib_cps(m - 1, fun a -> fib_cps(m - 2, fun b -> cnt (a + b)))
```

72

A closer look

The rest of the computation after computing “fib(m)”. That is, cnt is a function expecting the result of “fib(m)” as its argument.

```
let rec fib_cps (m, cnt) =  
  if m = 0  
  then cnt 1  
  else if m = 1  
    then cnt 1  
    else fib_cps(m - 1, fun a -> fib_cps(m - 2, fun b -> cnt (a + b)))
```

This makes explicit the order of evaluation that is implicit in the original “fib(m-1) + fib(m-2)”:
-- first compute fib(m-1)
-- then compute fib(m-1)
-- then add results together
-- then return

The computation waiting for the result of “fib(m-1)”

The computation waiting for the result of “fib(m-2)”

73

Expressed with “let” rather than “fun”

```
(* fib_cps_v2 : (int -> int) * int -> int *)  
let rec fib_cps_v2 (m, cnt) =  
  if m = 0  
  then cnt 1  
  else if m = 1  
    then cnt 1  
    else let cnt2 a b = cnt (a + b)  
      in let cnt1 a = fib_cps_v2(m - 2, cnt2 a)  
      in fib_cps_v2(m - 1, cnt1)
```

Some prefer writing CPS forms without explicit funs

74

Use the identity continuation ...

```
(* fib_cps : int * (int -> int) -> int *)
let rec fib_cps (m, cnt) =
  if m = 0
  then cnt 1
  else if m = 1
  then cnt 1
  else fib_cps(m - 1, fun a -> fib_cps(m - 2, fun b -> cnt (a + b)))

let id (x : int) = x

let fib_1 x = fib_cps(x, id)

List.map fib_1 [0; 1; 2; 3; 4; 5; 6; 7; 8; 9; 10];;
= [1; 1; 2; 3; 5; 8; 13; 21; 34; 55; 89]
```

75

Correctness?

For all $c : \text{int} \rightarrow \text{int}$, for all m , $0 \leq m$, we have, $c(\text{fib } m) = \text{fib_cps}(m, c)$.

Proof: assume $c : \text{int} \rightarrow \text{int}$. By Induction on m . Base case : $m = 0$:

$$\text{fib_cps}(0, c) = c(1) = c(\text{fib}(0))$$

NB: This proof pretends that we can treat OCaml functions as ideal mathematical functions, which of course we cannot. OCaml functions might raise exceptions like "stack overflow" or "you burned my toast", and so on. But this is a convenient fiction as long as we remember to be careful.

Induction step: Assume for all $n < m$, $c(\text{fib } n) = \text{fib_cps}(n, c)$. (That is, we need course-of-values induction!)

```
fib_cps(m + 1, c)
= if m + 1 = 1
  then c 1
  else fib_cps((m+1) - 1, fun a -> fib_cps((m+1) - 2, fun b -> c (a + b)))
= if m + 1 = 1
  then c 1
  else fib_cps(m, fun a -> fib_cps(m-1, fun b -> c (a + b)))
= (by induction)
  if m + 1 = 1
  then c 1
  else (fun a -> fib_cps(m - 1, fun b -> c (a + b))) (fib m)
```

76

Correctness?

```
= if m + 1 = 1
  then c 1
  else fib_cps(m-1, fun b -> c ((fib m) + b))
= (by induction)
  if m + 1 = 1
  then c 1
  else (fun b -> c ((fib m) + b)) (fib (m-1))
= if m + 1 = 1
  then c 1
  else c ((fib m) + (fib (m-1)))
= c (if m + 1 = 1
  then 1
  else ((fib m) + (fib (m-1))))
= c(if m +1 = 1
  then 1
  else fib((m + 1) - 1) + fib ((m + 1) - 2))
= c (fib(m + 1))
```

77

QED.

Can we express fib_cps without a functional argument ?

```
(* fib_cps_v2 : (int -> int) * int -> int *)
let rec fib_cps_v2 (m, cnt) =
  if m = 0
  then cnt 1
  else if m = 1
    then cnt 1
  else let cnt2 a b = cnt (a + b)
        in let cnt1 a = fib_cps_v2(m - 2, cnt2 a)
            in fib_cps_v2(m - 1, cnt1)
```

Idea of “defunctionalisation” (DFC): replace id, cnt1 and cnt2 with instances of a new data type:

```
type cnt = ID | CNT1 of int * cnt | CNT2 of int * cnt
```

Now we need an “apply” function of type `cnt * int -> int`

78

“Defunctionalised” version of fib_cps

```
(* datatype to represent continuations *)
type cnt = ID | CNT1 of int * cnt | CNT2 of int * cnt

(* apply_cnt : cnt * int -> int *)
let rec apply_cnt = function
| (ID, a)      -> a
| (CNT1 (m, cnt), a) -> fib_cps_dfc(m - 2, CNT2 (a, cnt))
| (CNT2 (a, cnt), b) -> apply_cnt (cnt, a + b)

(* fib_cps_dfc : (cnt * int) -> int *)
and fib_cps_dfc (m, cnt) =
  if m = 0
  then apply_cnt(cnt, 1)
  else if m = 1
  then apply_cnt(cnt, 1)
  else fib_cps_dfc(m - 1, CNT1(m, cnt))

(* fib_2 : int -> int *)
let fib_2 m = fib_cps_dfc(m, ID)
```

79

Correctness?

Let $< c >$ be of type cnt representing
a continuation $c : \text{int} \rightarrow \text{int}$ constructed by fib_cps.

Proof left
as an
exercise!

Then

$\text{apply_cnt}(< c >, m) = c(m)$
and
 $\text{fib_cps}(n, c) = \text{fib_cps_dfc}(n, < c >).$

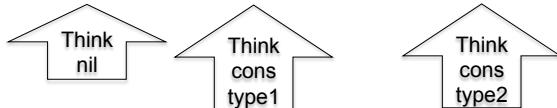

Functional continuation c	Representation $< c >$
<code>fun a -> fib_cps(m - 2, fun b -> cnt(a + b))</code>	<code>CNT1(m, < cnt >)</code>
<code>fun b -> cnt(a + b)</code>	<code>CNT2(a, < cnt >)</code>
<code>fun x -> x</code>	<code>ID</code>

80

Eureka! Continuations are just lists (used like a stack)

```
type int_list = NIL | CONS of int * int_list
```

```
type cnt = ID | CNT1 of int * cnt | CNT2 of int * cnt
```

Replace the above continuations with lists! (I've selected more suggestive names for the constructors.)

```
type tag = SUB2 of int | PLUS of int
type tag_list_cnt = tag list
```

81

The continuation lists are used like a stack!

```
type tag = SUB2 of int | PLUS of int
type tag_list_cnt = tag list

(* apply_tag_list_cnt : tag_list_cnt * int -> int *)
let rec apply_tag_list_cnt = function
| ([]), a)           -> a
| ((SUB2 m) :: cnt, a) -> fib_cps_dfc_tags(m - 2, (PLUS a):: cnt)
| ((PLUS a) :: cnt, b) -> apply_tag_list_cnt (cnt, a + b)

(* fib_cps_dfc_tags : (tag_list_cnt * int) -> int *)
and fib_cps_dfc_tags (m, cnt) =
  if m = 0
  then apply_tag_list_cnt(cnt, 1)
  else if m = 1
  then apply_tag_list_cnt(cnt, 1)
  else fib_cps_dfc_tags(m - 1, (SUB2 m) :: cnt)

(* fib_3 : int -> int *)
let fib_3 m = fib_cps_dfc_tags(m, [])
```

82

Combine Mutually tail-recursive functions into a single function

```

type state_type =
| SUB1 (* for right-hand-sides starting with fib_ *)
| APPL (* for right-hand-sides starting with apply_ *)

type state = (state_type * int * tag_list_cnt) -> int

(* eval : state -> int           A two-state transition function*)
let rec eval = function
| (SUB1, 0,          cnt) -> eval (APPL, 1,          cnt)
| (SUB1, 1,          cnt) -> eval (APPL, 1,          cnt)
| (SUB1, m,          cnt) -> eval (SUB1, (m-1), (SUB2 m) :: cnt)
| (APPL, a, (SUB2 m) :: cnt) -> eval (SUB1, (m-2), (PLUS a) :: cnt)
| (APPL, b, (PLUS a) :: cnt) -> eval (APPL, (a+b),          cnt)
| (APPL, a,          []) -> a

(* fib_4 : int -> int *)
let fib_4 m = eval (SUB1, m, [])

```

83

Eliminate tail recursion to obtain The Fibonacci Machine!

```

(* step : state -> state *)
let step = function
| (SUB1, 0,          cnt) -> (APPL, 1,          cnt)
| (SUB1, 1,          cnt) -> (APPL, 1,          cnt)
| (SUB1, m,          cnt) -> (SUB1, (m-1), (SUB2 m) :: cnt)
| (APPL, a, (SUB2 m) :: cnt) -> (SUB1, (m-2), (PLUS a) :: cnt)
| (APPL, b, (PLUS a) :: cnt) -> (APPL, (a+b),          cnt)
| _ -> failwith "step : runtime error!"

(* clearly TAIL RECURSIVE! *)
let rec driver state = function
| (APPL, a, []) -> a
| state      -> driver (step state)

In this version we have
simply made the
tail-recursive
structure very explicit.

```

```

(* fib_5 : int -> int *)
let fib_5 m = driver (SUB1, m, [])

```

84

Here is a trace of fib_5 6.

```

1 SUB1 || 6 || []
2 SUB1 || 5 || [SUB2 6]

49 APPL || 5 || [PLUS 8]
50 APPL || 13 || []

```

The OCaml file in basic_transformations/fibonacci_machine.ml contains some code for pretty printing such traces....

85

Pause to reflect

- **What have we accomplished?**
- We have taken a recursive function and turned it into an iterative function that does not require “stack space” for its evaluation (in OCaml)
- However, this function now carries its own evaluation stack as an extra argument!
- We have derived this iterative function in a step-by-step manner where each tiny step is easily proved correct.
- Wow!

86

That was fun! Let's do it again!

```
type expr =
| INT of int
| PLUS of expr * expr
| SUBT of expr * expr
| MULT of expr * expr
```

This time we will derive a stack-machine AND a “compiler” that translates expressions into a list of instructions for the machine.

```
(* eval : expr -> int
  a simple recursive evaluator for expressions *)
let rec eval = function
| INT a          -> a
| PLUS(e1, e2)   -> (eval e1) + (eval e2)
| SUBT(e1, e2)   -> (eval e1) - (eval e2)
| MULT(e1, e2)   -> (eval e1) * (eval e2)
```

87

Here we go again : CPS

```
type cnt_2 = int -> int

type state_2 = expr * cnt_2

(* eval_aux_2 : state_2 -> int *)
let rec eval_aux_2 (e, cnt) =
  match e with
  | INT a          -> cnt a
  | PLUS(e1, e2)   ->
    eval_aux_2(e1, fun v1 -> eval_aux_2(e2, fun v2 -> cnt(v1 + v2)))
  | SUBT(e1, e2)   ->
    eval_aux_2(e1, fun v1 -> eval_aux_2(e2, fun v2 -> cnt(v1 - v2)))
  | MULT(e1, e2)   ->
    eval_aux_2(e1, fun v1 -> eval_aux_2(e2, fun v2 -> cnt(v1 * v2)))

(* id_cnt : cnt_2 *)
let id_cnt (x : int) = x

(* eval_2 : expr -> int *)
let eval_2 e = eval_aux_2(e, id_cnt)
```

88

Defunctionalise!

```
type cnt_3 =
| ID
| OUTER_PLUS of expr * cnt_3
| OUTER_SUBT of expr * cnt_3
| OUTER_MULT of expr * cnt_3
| INNER_PLUS of int * cnt_3
| INNER_SUBT of int * cnt_3
| INNER_MULT of int * cnt_3

type state_3 = expr * cnt_3

(* apply_3 : cnt_3 * int -> int *)
let rec apply_3 = function
| (ID, v) -> v
| (OUTER_PLUS(e2, cnt), v1) -> eval_aux_3(e2, INNER_PLUS(v1, cnt))
| (OUTER_SUBT(e2, cnt), v1) -> eval_aux_3(e2, INNER_SUBT(v1, cnt))
| (OUTER_MULT(e2, cnt), v1) -> eval_aux_3(e2, INNER_MULT(v1, cnt))
| (INNER_PLUS(v1, cnt), v2) -> apply_3(cnt, v1 + v2)
| (INNER_SUBT(v1, cnt), v2) -> apply_3(cnt, v1 - v2)
| (INNER_MULT(v1, cnt), v2) -> apply_3(cnt, v1 * v2) 89
```

Defunctionalise!

```
(* eval_aux_2 : state_3 -> int *)
and eval_aux_3 (e, cnt) =
  match e with
  | INT a      -> apply_3(cnt, a)
  | PLUS(e1, e2) -> eval_aux_3(e1, OUTER_PLUS(e2, cnt))
  | SUBT(e1, e2) -> eval_aux_3(e1, OUTER_SUBT(e2, cnt))
  | MULT(e1, e2) -> eval_aux_3(e1, OUTER_MULT(e2, cnt))

(* eval_3 : expr -> int *)
let eval_3 e = eval_aux_3(e, ID)
```

90

Eureka! Again we have a stack!

```
type tag =
| O_PLUS of expr
| I_PLUS of int
| O_SUBT of expr
| I_SUBT of int
| O_MULT of expr
| I_MULT of int

type cnt_4 = tag list
type state_4 = expr * cnt_4

(* apply_4 : cnt_4 * int -> int *)
let rec apply_4 = function
| ([] , v) -> v
| ((O_PLUS e2) :: cnt, v1) -> eval_aux_4(e2, (I_PLUS v1) :: cnt)
| ((O_SUBT e2) :: cnt, v1) -> eval_aux_4(e2, (I_SUBT v1) :: cnt)
| ((O_MULT e2) :: cnt, v1) -> eval_aux_4(e2, (I_MULT v1) :: cnt)
| ((I_PLUS v1) :: cnt, v2) -> apply_4(cnt, v1 + v2)
| ((I_SUBT v1) :: cnt, v2) -> apply_4(cnt, v1 - v2)
| ((I_MULT v1) :: cnt, v2) -> apply_4(cnt, v1 * v2)
```

91

Eureka! Again we have a stack!

```
(* eval_aux_4 : state_4 -> int *)
and eval_aux_4 (e, cnt) =
  match e with
  | INT a           -> apply_4(cnt, a)
  | PLUS(e1, e2) -> eval_aux_4(e1, O_PLUS(e2) :: cnt)
  | SUBT(e1, e2) -> eval_aux_4(e1, O_SUBT(e2) :: cnt)
  | MULT(e1, e2) -> eval_aux_4(e1, O_MULT(e2) :: cnt)

(* eval_4 : expr -> int *)
let eval_4 e = eval_aux_4(e, [])
```

92

Eureka! Can combine apply_4 and eval_aux_4

```

type acc =
| A_INT of int
| A_EXP of expr

type cnt_5 = cnt_4

type state_5 = cnt_5 * acc

val : step : state_5 -> state_5

val driver : state_5 -> int

val eval_5 : expr -> int

```

Type of an “accumulator” that contains either an int or an expression.

The driver will be clearly tail-recursive ...

93

Rewrite to use driver, accumulator

```

let step_5 = function
  | (cnt,           A_EXP (INT a)) -> (cnt, A_INT a)
  | (cnt,   A_EXP (PLUS(e1, e2))) -> (O_PLUS(e2) :: cnt, A_EXP e1)
  | (cnt,   A_EXP (SUBT(e1, e2))) -> (O_SUBT(e2) :: cnt, A_EXP e1)
  | (cnt,   A_EXP (MULT(e1, e2))) -> (O_MULT(e2) :: cnt, A_EXP e1)
  | ((O_PLUS e2) :: cnt, A_INT v1) -> ((I_PLUS v1) :: cnt, A_EXP e2)
  | ((O_SUBT e2) :: cnt, A_INT v1) -> ((I_SUBT v1) :: cnt, A_EXP e2)
  | ((O_MULT e2) :: cnt, A_INT v1) -> ((I_MULT v1) :: cnt, A_EXP e2)
  | ((I_PLUS v1) :: cnt, A_INT v2) -> (cnt, A_INT (v1 + v2))
  | ((I_SUBT v1) :: cnt, A_INT v2) -> (cnt, A_INT (v1 - v2))
  | ((I_MULT v1) :: cnt, A_INT v2) -> (cnt, A_INT (v1 * v2))
  | ([] ,           A_INT v) -> ([] , A_INT v)

let rec driver_5 = function
  | ([] , A_INT v) -> v
  | state      -> driver_5 (step_5 state)

let eval_5 e = driver_5 ([] , A_EXP e)

```

94

Eureka! There are really two independent stacks here --- one for “expressions” and one for values

```

type directive =
| E of expr
| DO_PLUS
| DO_SUBT
| DO_MULT

type directive_stack = directive list

type value_stack = int list

type state_6 = directive_stack * value_stack

val step_6 : state_6 -> state_6

val driver_6 : state_6 -> int

val exp_6 : expr -> int

```

The state is now
two stacks!

95

Split into two stacks

```

let step_6 = function
| (E(INT v) :: ds,          vs) -> (ds, v :: vs)
| (E(PLUS(e1, e2)) :: ds,   vs) -> ((E e1) :: (E e2) :: DO_PLUS :: ds, vs)
| (E(SUBT(e1, e2)) :: ds,   vs) -> ((E e1) :: (E e2) :: DO_SUBT :: ds, vs)
| (E(MULT(e1, e2)) :: ds,   vs) -> ((E e1) :: (E e2) :: DO_MULT :: ds, vs)

| (DO_PLUS :: ds, v2 :: v1 :: vs) -> (ds, (v1 + v2) :: vs)
| (DO_SUBT :: ds, v2 :: v1 :: vs) -> (ds, (v1 - v2) :: vs)
| (DO_MULT :: ds, v2 :: v1 :: vs) -> (ds, (v1 * v2) :: vs)
| _ -> failwith "eval : runtime error!"

let rec driver_6 = function
| ([] , [v]) -> v
| state    -> driver_6 (step_6 state)

let eval_6 e = driver_6 ([E e], [])

```

96

An eval_6 trace

e = PLUS(MULT(INT 89, INT 2), SUBT(INT 10, INT 4))

inspect	state 1 DS = [E(PLUS(MULT(INT(89), INT(2)), SUBT(INT(10), INT(4))))] VS = []
compute	state 2 DS = [DO_PLUS; E(SUBT(INT(10), INT(4))); E(MULT(INT(89), INT(2)))] VS = []
inspect	state 3 DS = [DO_PLUS; E(SUBT(INT(10), INT(4))); DO_MULT; E(INT(2)); E(INT(89))] VS = []
compute	state 4 DS = [DO_PLUS; E(SUBT(INT(10), INT(4))); DO_MULT; E(INT(2))] VS = [89]
inspect	state 5 DS = [DO_PLUS; E(SUBT(INT(10), INT(4))); DO_MULT] VS = [89; 2]
compute	state 6 DS = [DO_PLUS; E(SUBT(INT(10), INT(4)))] VS = [178]
inspect	state 7 DS = [DO_PLUS; DO_SUBT; E(INT(4)); E(INT(10))] VS = [178]
compute	state 8 DS = [DO_PLUS; DO_SUBT; E(INT(4))] VS = [178; 10]
inspect	state 9 DS = [DO_PLUS; DO_SUBT] VS = [178; 10; 4]
compute	state 10 DS = [DO_PLUS] VS = [178; 6]
	state 11 DS = [] VS = [184]

Top of each stack is on the right

Key insight

This evaluator is interleaving two distinct computations:

- (1) decomposition of the input expression into sub-expressions
- (2) the computation of +, -, and *

Idea: why not do the decomposition BEFORE the computation?

Key insight: An interpreter can (usually) be refactored into a translation (compilation!) followed by a lower-level interpreter.

Interpret_higher (e) = interpret_lower(compile(e))

Note : this can occur at many levels of abstraction: think of machine code being interpreted in micro-code ...

98

Refactor --- compile!

```
(* low-level instructions *)
type instr =
| Ipush of int
| Iplus
| Isubt
| Imult

type code = instr list
```

Never put off till run-time what you can do at compile-time.
-- David Gries

```
type state_7 = code * value_stack

(* compile : expr -> code *)
let rec compile = function
| INT a           -> [Ipush a]
| PLUS(e1, e2)   -> (compile e1) @ (compile e2) @ [Iplus]
| SUBT(e1, e2)   -> (compile e1) @ (compile e2) @ [Isubt]
| MULT(e1, e2)   -> (compile e1) @ (compile e2) @ [Imult]
```

99

Evaluate compiled code.

```
(* step_7 : state_7 -> state_7 *)
let step_7 = function
| (Ipush v :: is,      vs) -> (is, v :: vs)
| (Iplus :: is, v2::v1::vs) -> (is, (v1 + v2) :: vs)
| (Isubt :: is, v2::v1::vs) -> (is, (v1 - v2) :: vs)
| (Imult :: is, v2::v1::vs) -> (is, (v1 * v2) :: vs)
| _ -> failwith "eval : runtime error!"

let rec driver_7 = function
| ([]), [v] -> v
| _ -> driver_7 (step_7 state)

let eval_7 e = driver_7 (compile e, [])
```

100

An eval_7 trace

inspect {

```
compile (PLUS(MULT(INT 89, INT 2), SUBT(INT 10, INT 4)))
      = [push 89; push 2; mult; push 10; push 4; subt; plus]
```

compute {

state 1	IS = [add; sub; push 4; push 10; mul; push 2; push 89]
	VS = []
state 2	IS = [add; sub; push 4; push 10; mul; push 2]
	VS = [89]
state 3	IS = [add; sub; push 4; push 10; mul]
	VS = [89; 2]
state 4	IS = [add; sub; push 4; push 10]
	VS = [178]
state 5	IS = [add; sub; push 4]
	VS = [178; 10]
state 6	IS = [add; sub]
	VS = [178; 10; 4]
state 7	IS = [add]
	VS = [178; 6]
state 8	IS = [] VS = [184]

Top of each stack is on the right

Interp_0.ml → interp_1.ml → interp_2.ml

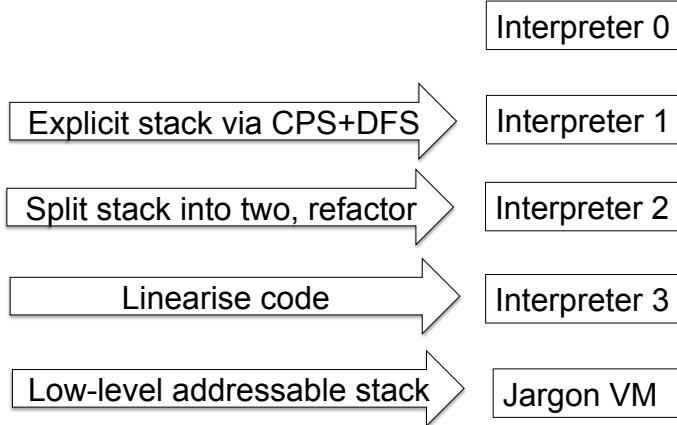

The derivation from eval to compile+eval_7 can be used as a guide to a derivation from Interpreter 0 to interpreter 2.

1. Apply CPS to the code of Interpreter 0
2. Defunctionalise
3. Arrive at interpreter 1, which has a single continuation stack containing expressions, values and environments
4. Spit this stack into two stacks : one for instructions and the other for values and environments
5. Refactor into compiler + lower-level interpreter
6. Arrive at interpreter 2.

102

Taking stock

Starting from a direct implementation of Slang/L3 semantics, we have **DERIVED** a Virtual Machine in a step-by-step manner. The correctness of each step is (more or less) easy to check.

103
