Inclusions

We have the following inclusions:

$$\mathsf{L} \subseteq \mathsf{NL} \subseteq \mathsf{P} \subseteq \mathsf{NP} \subseteq \mathsf{PSPACE} \subseteq \mathsf{NPSPACE} \subseteq \mathsf{EXP}$$

where $\mathsf{EXP} = \bigcup_{k=1}^{\infty} \mathsf{TIME}(2^{n^k})$

Moreover,

$$\mathsf{L} \subseteq \mathsf{NL} \cap \mathsf{co\text{-}NL}$$

$$\mathsf{P} \subseteq \mathsf{NP} \cap \mathsf{co\text{-}NP}$$

$$\mathsf{PSPACE} \subseteq \mathsf{NPSPACE} \cap \mathsf{co\text{-}NPSPACE}$$

Reachability

Recall the Reachability problem: given a *directed* graph $G = (V, E)$ and two nodes $a, b \in V$, determine whether there is a path from a to b in G.

A simple search algorithm solves it:

1. mark node a, leaving other nodes unmarked, and initialise set S to $\{a\}$;
2. while S is not empty, choose node i in S: remove i from S and for all j such that there is an edge (i, j) and j is unmarked, mark j and add j to S;
3. if b is marked, accept else reject.

NL Reachability

We can construct an algorithm to show that the Reachability problem is in NL:

1. write the index of node a in the work space;
2. if i is the index currently written on the work space:
   (a) if $i = b$ then accept, else
   guess an index j ($\log n$ bits) and write it on the work space.
   (b) if (i, j) is not an edge, reject, else replace i by j and return to (2).

$O((\log n)^2)$ space Reachability algorithm:

Path(a, b, i)

if $i = 1$ and $a \neq b$ and (a, b) is not an edge reject
else if (a, b) is an edge or $a = b$ accept
else, for each node x, check:

1. is there a path $a - x$ of length $i/2$; and
2. is there a path $x - b$ of length $i/2$?

if such an x is found, then accept, else reject.

The maximum depth of recursion is $\log n$, and the number of bits of information kept at each stage is $3 \log n$.

Savitch's Theorem

The space efficient algorithm for reachability used on the configuration graph of a nondeterministic machine shows:

$$\mathsf{NSPACE}(f) \subseteq \mathsf{SPACE}(f^2)$$

for $f(n) \geq \log n$.

This yields

$$\mathsf{PSPACE} = \mathsf{NPSPACE} = \text{co-}\mathsf{NPSPACE}.$$

Complementation

A still more clever algorithm for Reachability has been used to show that nondeterministic space classes are closed under complementation:

If $f(n) \geq \log n$, then

$$\mathsf{NSPACE}(f) = \text{co-}\mathsf{NSPACE}(f)$$

In particular

$$\mathsf{NL} = \text{co-}\mathsf{NL}.$$

Logarithmic Space Reductions

We write

$$A \leq_L B$$

if there is a reduction f of A to B that is computable by a deterministic Turing machine using $O(\log n)$ workspace (with a *read-only* input tape and *write-only* output tape).

Note: We can compose $\leq_L$ reductions. So,

$$\text{if } A \leq_L B \text{ and } B \leq_L C \text{ then } A \leq_L C$$

NP-complete Problems

Analysing carefully the reductions we constructed in our proofs of NP-completeness, we can see that SAT and the various other NP-complete problems are actually complete under $\leq_L$ reductions.

Thus, if SAT $\leq_L A$ for some problem A in L then not only P $=$ NP but also L $=$ NP.

P-complete Problems

It makes little sense to talk of complete problems for the class P with respect to polynomial time reducibility $\leq_P$.

There are problems that are complete for P with respect to *logarithmic space* reductions $\leq_L$.

One example is CVP—the circuit value problem.

- If CVP $\in$ L then L $=$ P.
- If CVP $\in$ NL then NL $=$ P.

CVP

CVP - the *circuit value problem* is, given a circuit, determine the value of the result node n.

CVP is solvable in polynomial time, by the algorithm which examines the nodes in increasing order, assigning a value `true` or `false` to each node.

CVP is complete for P under L reductions.

That is, for every language A in P,

$$A \leq_L \text{CVP}$$

Reachability

Similarly, it can be shown that Reachability is, in fact, NL-complete.

For any language $A \in \mathsf{NL}$, we have $A \leq_L$ Reachability

L = NL if, and only if, Reachability $\in$ L

Note: it is known that the reachability problem for *undirected* graphs is in L.

Provable Intractability

Our aim now is to show that there are languages (*or, equivalently, decision problems*) that we can prove are not in P.

This is done by showing that, for every *reasonable* function f, there is a language that is not in $\mathsf{TIME}(f)$.

The proof is based on the diagonal method, as in the proof of the undecidability of the halting problem.

Time Hierarchy Theorem

For any constructible function f, with $f(n) \geq n$, define the f-bounded *halting language* to be:

$$H_f = \{[M], x \mid M \text{ accepts } x \text{ in } f(|x|) \text{ steps}\}$$

where $[M]$ is a description of M in some fixed encoding scheme.

Then, we can show

$H_f \in \mathsf{TIME}(f(n)^2)$ and $H_f \notin \mathsf{TIME}(f(\lfloor n/2 \rfloor))$

Time Hierarchy Theorem

For any constructible function $f(n) \geq n$, $\mathsf{TIME}(f(n))$ is properly contained in $\mathsf{TIME}(f(2n+1)^2)$.

Strong Hierarchy Theorems

For any constructible function $f(n) \geq n$, $\mathsf{TIME}(f(n))$ is properly contained in $\mathsf{TIME}(f(n)(\log f(n)))$.

Space Hierarchy Theorem
For any pair of constructible functions f and g, with $f = O(g)$ and $g \neq O(f)$, there is a language in $\mathsf{SPACE}(g(n))$ that is not in $\mathsf{SPACE}(f(n))$.

Similar results can be established for nondeterministic time and space classes.

Consequences

- For each k, $\mathsf{TIME}(n^k) \neq \mathsf{P}$.
- $\mathsf{P} \neq \mathsf{EXP}$.
- $\mathsf{L} \neq \mathsf{PSPACE}$.
- Any language that is EXP-complete is not in P.
- There are no problems in P that are complete under linear time reductions.
