## **Provable Intractability**

Our aim now is to show that there are languages (*or, equivalently, decision problems*) that we can prove are not in P.

This is done by showing that, for every *reasonable* function f, there is a language that is not in  $\mathsf{TIME}(f)$ .

The proof is based on the diagonal method, as in the proof of the undecidability of the halting problem.

## **Time Hierarchy Theorem**

For any constructible function f, with  $f(n) \ge n$ , define the f-bounded halting language to be:

 $H_f = \{ [M], x \mid M \text{ accepts } x \text{ in } f(|x|) \text{ steps} \}$ 

where [M] is a description of M in some fixed encoding scheme. Then, we can show

 $H_f \in \mathsf{TIME}(f(n)^3) \text{ and } H_f \notin \mathsf{TIME}(f(\lfloor n/2 \rfloor))$ 

#### **Time Hierarchy Theorem**

For any constructible function  $f(n) \ge n$ ,  $\mathsf{TIME}(f(n))$  is properly contained in  $\mathsf{TIME}(f(2n+1)^3)$ .

## **Strong Hierarchy Theorems**

For any constructible function  $f(n) \ge n$ ,  $\mathsf{TIME}(f(n))$  is properly contained in  $\mathsf{TIME}(f(n)(\log f(n)))$ .

### **Space Hierarchy Theorem**

For any pair of constructible functions f and g, with f = O(g) and  $g \neq O(f)$ , there is a language in  $\mathsf{SPACE}(g(n))$  that is not in  $\mathsf{SPACE}(f(n))$ .

Similar results can be established for nondeterministic time and space classes.

### **Consequences**

- For each k,  $\mathsf{TIME}(n^k) \neq \mathsf{P}$ .
- $P \neq EXP$ .
- $L \neq PSPACE$ .
- Any language that is **EXP**-complete is not in **P**.
- There are no problems in P that are complete under linear time reductions.

## **Descriptive Complexity**

*Descriptive Complexity* is an attempt to study the complexity of problems and classify them, not on the basis of how difficult it is to *compute* solutions, but on the basis of how difficult it is to *describe* the problem.

This gives an alternative way to study complexity, independent of particular machine models.

Based on *definability in logic*.

### **Graph Properties**

As an example, consider the following three decision problems on *graphs*.

- 1. Given a graph G = (V, E) does it contain a *triangle*?
- 2. Given a directed graph G = (V, E) and two of its vertices  $a, b \in V$ , does G contain a *path* from a to b?
- 3. Given a graph G = (V, E) is it *3-colourable*? That is, is there a function  $\chi : V \to \{1, 2, 3\}$  so that whenever  $(u, v) \in E, \ \chi(u) \neq \chi(v).$

## **Graph Properties**

1. Checking if G contains a triangle can be solved in *polynomial* time and *logarithmic space*.

2. Checking if G contains a path from a to b can be done in *polynomial time*.

Can it be done in *logarithmic space*?

Unlikely. It is NL-complete.

3. Checking if G is 3-colourable can be done in *exponential time* and *polynomial space*.

Can it be done in *polynomial time*?

Unlikely. It is NP-complete.

## **Logical Definability**

In what kind of formal language can these decision problems be *specified* or *defined*?

The graph G = (V, E) contains a triangle.

 $\exists x, y, z \in V(x \neq y \land y \neq z \land x \neq z \land E(x, y) \land E(x, z) \land E(y, z))$ 

The other two properties are *provably* not definable with only first-order quantification over vertices.

## **First-Order Logic**

Consider *first-order predicate logic*.

A collection of variables  $x, y, \ldots$ , and formulas:  $E(x, y) \mid \phi \land \psi \mid \phi \lor \psi \mid \neg \phi \mid \exists x \phi \mid \forall x \phi$ 

Any property of graphs that is expressible in *first-order logic* is in L.

The problem of deciding whether  $G \models \phi$  for a first-order  $\phi$  is in time  $O(ln^m)$  and  $O(m \log n)$  space.

where, l is the *length* of  $\phi$  and n the *order* of G and m is the nesting depth of quantifiers in  $\phi$ .

# **Complexity of First-Order Logic**

The straightforward algorithm proceeds recursively on the structure of  $\phi$ :

- Atomic formulas by direct lookup.
- Boolean connectives are easy.
- If  $\phi \equiv \exists x \psi$  then for each v in G check whether

 $(G, x \mapsto v) \models \psi.$ 

## **Second-Order Quantifiers**

*3-Colourability* and *Reachability* can be defined with quantification over *sets of vertices*.

 $\exists R \subseteq V \exists B \subseteq V \exists G \subseteq V$  $\forall x (Rx \lor Bx \lor Gx) \land$  $\forall x (\neg (Rx \land Bx) \land \neg (Bx \land Gx) \land \neg (Rx \land Gx)) \land$  $\forall x \forall y (Exy \rightarrow (\neg (Rx \land Ry) \land \\ \neg (Bx \land By) \land \\ \neg (Gx \land Gy)))$ 

 $\forall S \subseteq V(a \in S \land \forall x \forall y((x \in S \land E(x, y)) \to y \in S) \to b \in S)$ 

## **Existential Second-Order Logic**

Second-order logic is obtained by adding to the defining rules of first-order logic two further clauses:

atomic formulae  $-X(t_1, \ldots, t_a)$ , where X is a *second-order* variable

second-order quantifiers  $-\exists X\phi, \forall X\phi$ 

*Existential Second-Order Logic* (ESO) consists of formulas of the form

 $\exists X_1 \cdots \exists X_k \phi$ 

where  $\phi$  is *first-order* 

## **Fagin's Theorem**

### Theorem (Fagin)

A class of graphs is definable by a formula of *existential second-order logic* if, and only if, it is decidable by a *nondeterminisitic machine* running in polynomial time.

#### $\mathsf{ESO} = \mathsf{NP}$

One direction is easy: Given G and  $\exists X_1 \dots \exists X_k \phi$ .

a nondeterministic machine can guess an interpretation for  $X_1, \ldots, X_k$  and then verify  $\phi$ .

The other direction requires a proof similar to Cook's theorem.

Is there a logic, intermediate between first and second-order logic that expresses exactly graph properties in P?

This is an open question, still the subject of active research.
