Acknowledgements

These slides are heavily based on previous versions by Mike Gordon, Alan Mycroft, and Kasper Svendsen.

Thanks to Julia Bibik, Mistral Contrastin, Victor Gomes, Joe Isaacs, Hrutvik Kanabar, Neel Krishnaswami, Ian Orton, Peter Sewell, and Domagoj Stolfa for remarks and reporting mistakes.

Motivation

We often fail to write programs that meet our expectations, which we phrased in their specifications:

- we fail to write programs that meet their specification;
- we fail to write specifications that meet our expectations.

Addressing the former issue is called verification, and addressing the latter is called validation.

In practice, verification and validation feed back into each other.

Background

There are many verification & validation techniques of varying coverage, expressivity, level of automation, ..., for example:

- typing
- testing
- model checking
- program logics
- operational reasoning

expressivity (of safety properties)

coverage:
- complete
- bounded
- sparse
Choice of technique

More expressive and complete techniques lead to more confidence.

It is important to choose the right set of verification & validation techniques for the task at hand:

• verified designs may still not work;
• verification can give a false sense of security;
• verification can be very expensive and time-consuming.

More heavyweight techniques should be used together with testing, not as a replacement.

Course structure

This course is about two techniques, their underlying ideas, how to use them, and why they are correct:

• Hoare logic (Lectures 1-6);
• Model checking (Lectures 7-12).

These are not just techniques, but also ways of thinking about programs.

Lecture plan

Lecture 1: Informal introduction to Hoare logic
Lecture 2: Examples, loop invariants, and mechanisation
Lecture 3: Formal semantics and properties of Hoare logic
Lecture 4: Introduction to separation logic
Lecture 5: Verifying abstract data types in separation logic
Lecture 6: Extending Hoare logic
Hoare logic is a formalism for relating the initial and terminal state of a program. Hoare logic was invented in 1969 by Tony Hoare, inspired by earlier work of Robert Floyd. There was little-known prior work by Alan Turing. Hoare logic is still an active area of research.

Partial correctness triples

Hoare logic uses partial correctness triples (also "Hoare triples") for specifying and reasoning about the behaviour of programs:

\{P\} \ C \ \{Q\}

is a logical statement about a command \(C\), where \(P\) and \(Q\) are state predicates:

- \(P\) is called the precondition, and describes the initial state;
- \(Q\) is called the postcondition, and describes the terminal state.

Components of a Hoare logic

To define a Hoare logic, we need four main components:

- the programming language that we want to reason about: its syntax and dynamic (e.g. operational) semantics;
- an assertion language for defining state predicates: its syntax and an interpretation;
- an interpretation of Hoare triples;
- a (sound) syntactic proof system for deriving Hoare triples.

This lecture will introduce each component informally. In the coming lectures, we will cover the formal details.
Commands of the WHILE language

WHILE is the prototypical imperative language. Programs consist of commands, which include branching, iteration, and assignment:

\[
\begin{align*}
C & ::= \text{skip} \\
     & | \ C_1; \ C_2 \\
     & | \ X := E \\
     & | \ \text{if } B \text{ then } \ C_1 \text{ else } \ C_2 \\
     & | \ \text{while } B \text{ do } \ C
\end{align*}
\]

Here, \(X\) is a variable, \(E\) is an arithmetic expression, which evaluates to an integer, and \(B\) is a boolean expression, which evaluates to a boolean.

States are mappings from variables to integers, \(\text{Var} \rightarrow \mathbb{Z}\).

Expressions of the WHILE language

The grammar for arithmetic expressions and boolean expressions includes the usual arithmetic operations and comparison operators, respectively:

\[
\begin{align*}
E & ::= \ N | \ X | E_1 + E_2 & \text{arithmetic expressions} \\
    & | \ E_1 - E_2 | E_1 \times E_2 | \cdots \\
B & ::= \ T | \ F | E_1 = E_2 & \text{boolean expressions} \\
    & | \ E_1 \leq E_2 | E_1 \geq E_2 | \cdots
\end{align*}
\]

Expressions do not have side effects.

Assertions and specifications

Assertions (also "state predicates") \(P, Q, \ldots\) include boolean expressions (which can contain program variables), combined using the usual logical operators: \(\land, \lor, \neg, \Rightarrow, \forall, \exists, \ldots\).

For instance, the predicate \(X = Y + 1 \land Y > 0\) describes states in which the variable \(Y\) contains a positive value, and the value of \(X\) is equal to the value of \(Y\) plus 1.
The partial correctness triple \( \{ P \} C \{ Q \} \) holds if and only if:
- assuming \( C \) is executed in an initial state satisfying \( P \),
- and assuming moreover that this execution terminates,
- then the terminal state of the execution satisfies \( Q \).

For instance,
- \( \{ X = 1 \} X := X + 1 \{ X = 2 \} \) holds;
- \( \{ X = 1 \} X := X + 1 \{ X = 3 \} \) does not hold.

Partial correctness triples are called \textbf{partial} because they only specify the intended behaviour of terminating executions.

For instance, \( \{ X = 1 \} \textbf{while } X > 0 \textbf{ do } X := X + 1 \{ X = 0 \} \) holds, because the given program never terminates when executed from an initial state where \( X \) is 1.

Later, we will see that it is also possible to have total correctness triples that strengthen partial correctness triples to require termination.

Corner cases of partial correctness triples

\( \{ \bot \} C \{ Q \} \)
- this says nothing about the behaviour of \( C \), because \( \bot \) never holds for any initial state.

\( \{ \top \} C \{ Q \} \)
- this says that whenever \( C \) halts, \( Q \) holds.

\( \{ P \} C \{ \top \} \)
- this holds for every precondition \( P \) and command \( C \), because \( \top \) always holds in the terminate state.
The need for auxiliary variables

How can we specify that a program \( C \) computes the maximum of two variables \( X \) and \( Y \), and stores the result in a variable \( Z \)?

Is this a good specification for \( C \)?

\[
\{ \top \} \ C \{ (X \leq Y \Rightarrow Z = Y) \land (Y \leq X \Rightarrow Z = X) \}
\]

No! Take \( C \) to be

\[
X := 0; \ Y := 0; \ Z := 0
\]

Then \( C \) satisfies the above specification!

The postcondition should refer to the initial values of \( X \) and \( Y \).

Using auxiliary variables

In Hoare logic, we use auxiliary variables (also “ghost variables”, or “logical variables”), which are not allowed to occur in the program, to refer to the initial values of variables in postconditions.

Notation: program variables are uppercase, and auxiliary variables are lowercase.

Using auxiliary variables, we can specify \( C \) with

\[
\{ X = x \land Y = y \} \ C \{ (x \leq y \Rightarrow Z = y) \land (y \leq x \Rightarrow Z = x) \}
\]

Examples of partial correctness triples

\( C \) computes the Euclidian division of \( X \) by \( Y \) into \( Q \) and \( R \):

\[
\{ X = x \land Y = y \land x \geq 0 \land y > 0 \} \ C \{ x = Q \times y + R \}
\]

\( C \) tests whether \( P \) is prime:

\[
\{ P = p \land p > 0 \} \ C \{ (r = 0 \Rightarrow \exists q, r. q > 1 \land r > 1 \land p = q \times r) \land (r = 1 \Rightarrow \forall q, r. q > 1 \land r > 1 \Rightarrow p \neq q \times r) \}
\]
Formal proof system for Hoare logic

Inference rule schemas

The inference rule schemas of Hoare logic will be specified as follows:

\[
\frac{\vdash S_1 \quad \cdots \quad \vdash S_n}{\vdash S}
\]

This expresses that \( S \) may be deduced from assumptions \( S_1, ..., S_n \).

These are schemas that may contain meta-variables.

Proof trees

A proof tree for \( \vdash S \) in Hoare logic is a tree with \( \vdash S \) at the root, constructed using the inference rules of Hoare logic, where all nodes are shown to be derivable (so leaves require no further derivations):

\[
\frac{\vdash S_1 \quad \vdash S_2}{\vdash S_3} \quad \frac{\vdash S_3 \quad \vdash S_4}{\vdash S}
\]

We typically write proof trees with the root at the bottom.

Hoare logic

We will now introduce a natural deduction proof system for partial correctness triples due to Tony Hoare.

The logic consists of a set of inference rule schemas for deriving consequences from premises.

If \( S \) is a statement, we will write \( \vdash S \) to mean that the statement \( S \) is derivable. We will have two derivability judgements:

- \( \vdash P \), for derivability of assertions; and
- \( \vdash \{P\} C \{Q\} \), for derivability of partial correctness triples.
Formal proof system for Hoare logic

\[ \Gamma \vdash \{P\} \text{skip} \{P\} \]

\[ \Gamma \vdash \{P\} \text{C}_1 \{Q\} \quad \Gamma \vdash \{Q\} \text{C}_2 \{R\} \]

\[ \Gamma \vdash \{P\} \text{C}_1; \text{C}_2 \{R\} \]

\[ \Gamma \vdash \{P \land B\} \text{C}_1 \{Q\} \quad \Gamma \vdash \{P \land \neg B\} \text{C}_2 \{Q\} \]

\[ \Gamma \vdash \{P\} \text{if } B \text{ then } \text{C}_1 \text{ else } \text{C}_2 \{Q\} \]

\[ \Gamma \vdash \{P\} \text{while } B \text{ do } \text{C} \{P \land \neg B\} \]

\[ \Gamma \vdash P_1 \Rightarrow P_2 \quad \Gamma \vdash P_2 \text{C}_2 \{Q_2\} \quad \Gamma \vdash Q_2 \Rightarrow Q_1 \]

\[ \Gamma \vdash P_1 \text{C}_1 \{Q_1\} \]

The skip rule

\[ \Gamma \vdash \{P\} \text{skip} \{P\} \]

The skip rule expresses that any assertion that holds before \text{skip} is executed also holds afterwards.

\[ P \] is a meta-variable ranging over an arbitrary state predicate.

For instance, \[ \Gamma \vdash \{X = 1\} \text{skip} \{X = 1\} \].

The assignment rule

\[ \Gamma \vdash \{P[E/X]\} X := E \{P\} \]

Here, \( P[E/X] \) means the assertion \( P \) with the expression \( E \) substituted for all occurrences of the variable \( X \).

For instance,

\[ \Gamma \vdash \{X + 1 = 2\} X := X + 1 \{X = 2\} \]

\[ \Gamma \vdash \{Y + X = Y + 10\} X := Y + X \{X = Y + 10\} \]

The assignment rule reads right-to-left; could we use another rule that reads more easily?

Consider the following plausible alternative assignment rule:

\[ \Gamma \vdash \{P\} X := E \{P[E/X]\} \]

We can instantiate this rule to obtain the following triple, which does not hold:

\[ \{X = 0\} X := 1 \{1 = 0\} \]
The rule of consequence

\[ \vdash P_1 \Rightarrow P_2 \quad \vdash \{ P_2 \} \ C \ \{ Q_2 \} \quad \vdash Q_2 \Rightarrow Q_1 \]
\[ \vdash \{ P_1 \} \ C \ \{ Q_1 \} \]

The rule of consequence allows us to strengthen preconditions and weaken postconditions.

Note: the \( \vdash P \Rightarrow Q \) hypotheses are a different kind of judgment.

For instance, from \( \vdash \{ X + 1 = 2 \} \ X := X + 1 \ \{ X = 2 \} \),
we can deduce \( \vdash \{ X = 1 \} \ X := X + 1 \ \{ X = 2 \} \).

Sequential composition

\[ \vdash \{ P \} \ C_1 \ \{ Q \} \quad \vdash \{ Q \} \ C_2 \ \{ R \} \]
\[ \vdash \{ P \} \ C_1; \ C_2 \ \{ R \} \]

If the postcondition of \( C_1 \) matches the precondition of \( C_2 \),
we can derive a specification for their sequential composition.

For example, if we have deduced:
\( \vdash \{ X = 1 \} \ X := X + 1 \ \{ X = 2 \} \) and
\( \vdash \{ X = 2 \} \ X := X \times 2 \ \{ X = 4 \} \)
we may deduce \( \vdash \{ X = 1 \} \ X := X + 1; \ X := X \times 2 \ \{ X = 4 \} \).

The conditional rule

\[ \vdash \{ P \land B \} \ C_1 \ \{ Q \} \quad \vdash \{ P \land \neg B \} \ C_2 \ \{ Q \} \]
\[ \vdash \{ P \} \ \text{if } B \text{ then } C_1 \text{ else } C_2 \ \{ Q \} \]

For instance, to prove that
\( \vdash \{ \top \} \ \text{if } X \geq Y \text{ then } Z := X \text{ else } Z := Y \ \{ Z = \max(X, Y) \} \)
it suffices to prove that \( \vdash \{ \top \land X \geq Y \} \ Z := X \ \{ Z = \max(X, Y) \} \)
and \( \vdash \{ \top \land \neg (X \geq Y) \} \ Z := Y \ \{ Z = \max(X, Y) \} \).

The loop rule

\[ \vdash \{ P \land B \} \ C \ \{ P \} \]
\[ \vdash \{ P \} \ \text{while } B \text{ do } C \ \{ P \land \neg B \} \]

The loop rule says that
\( \bullet \) if \( P \) is an invariant of the loop body when the loop condition succeeds, then \( P \) is an invariant for the whole loop, and
\( \bullet \) if the loop terminates, then the loop condition failed.

We will return to the problem of finding loop invariants.
Example

Example: integer square root algorithm

We can use these rules to verify a very inefficient integer square root algorithm:

\[
\begin{align*}
&\{X = x \land x \geq 0\} \\
&S = 0; \textbf{while } (S + 1) \times (S + 1) \leq X \textbf{ do } S := S + 1 \\
&\{S \times S \leq x \land x < (S + 1) \times (S + 1)\}
\end{align*}
\]

Summary

Hoare logic is a formalism for reasoning about the behaviour of programs by relating their initial and terminal state.

It uses an assertion logic based on first-order logic to reason about program states, and defines Hoare triples on top of it to reason about the programs.

Papers of historical interest:

In the next lecture, we will use Hoare logic to reason about example programs.
Recap

In the previous lecture, we introduced Hoare logic, which uses partial correctness triples to specify the behaviour of imperative programs by relating the initial state of a program with its final state (when it terminates).

Today, we will use Hoare logic to specify and verify some simple programs.

We will first establish derived rules that make using Hoare logic easier.

Using these, we will then verify two simple programs to exercise Hoare logic, and to illustrate how to find invariants in Hoare logic.
Forward reasoning

The proof rules we have seen so far are best suited for **forward** (also “top down”) reasoning, where a proof tree is constructed starting from the leaves, going towards the root.

For instance, consider a proof of
\[ \vdash \{ X = a \} \ X := X + 1 \{ X = a + 1 \} \]
using the assignment rule:
\[ \vdash \{ P[E/X] \} \ X := E \{ P \} \]

Backwards reasoning & backwards assignment rule

It is often more natural to work **backwards** (also “bottom up”), starting from the root of the proof tree, and generating new subgoals until all the nodes have been shown to be derivable.

We can derive rules better suited for backwards reasoning.

For instance, we can derive this backwards assignment rule:

\[ \vdash P \Rightarrow Q[E/X] \]
\[ \vdash \{ P \} \ X := E \{ Q \} \]

This rule does not impose that the precondition is of a given shape, but instead that it implies an assertion of the desired shape.

Backwards assignment rule

We can derive the backwards assignment rule by combining the assignment rule with the rule of consequence:

\[ \vdash P \Rightarrow Q[E/X] \]
\[ \vdash \{ Q[E/X] \} \ X := E \{ Q \} \]
\[ \vdash \{ P \} \ X := E \{ Q \} \]
\[ \vdash P \Rightarrow Q \]

Proof of a simple assignment using the forward reasoning

\[ \vdash X = 1 \Rightarrow X + 1 = a + 1 \]
\[ \vdash \{ (X = a + 1)[X + 1/X] \} \ X := X + 1 \{ X = a + 1 \} \]
\[ \vdash X = a + 1 \Rightarrow X = a + 1 \]

Given that \((X = a + 1)[X + 1/X] \equiv X + 1 = a + 1\).
**Backwards sequenced assignment rule**

The sequence rule can already be applied bottom up, but requires us to guess an assertion $R$:

\[
\frac{\varnothing \vdash P \; ; \; C_1 \; ; \; C_2 \; \{Q\} }{\varnothing \vdash \{P\} \; ; \; C_1 \; ; \; C_2 \; \{Q\} }
\]

In the case of a command sequenced before an assignment, we can avoid having to guess $R$ by using the sequenced assignment rule:

\[
\frac{\varnothing \vdash P \; \{Q\} }{\varnothing \vdash \{P\} \; X := E \; \{Q\} }
\]

This is easily derivable using the sequencing rule and the backwards assignment rule (exercise).

**Backwards loop rule**

In the same way, we can derive a backwards reasoning rule for loops by building in consequence:

\[
\frac{\varnothing \vdash P \Rightarrow I \; \{I \land B\} \; C \; \{I\} \; \{I \land \neg B \Rightarrow Q\} }{\varnothing \vdash \{P\} \; \text{while} \; B \; \text{do} \; C \; \{Q\} }
\]

This rule still requires us to guess $I$ to apply it bottom-up.

**Backwards skip and conditional rules**

We can also derive a backwards skip rule that builds in consequence:

\[
\frac{\varnothing \vdash P \Rightarrow Q }{\varnothing \vdash \{P\} \; \text{skip} \; \{Q\} }
\]

The conditional rule needs not be changed:

\[
\frac{\varnothing \vdash (P \land B) \; C_1 \; \{Q\} \; \{P \land \neg B\} \; C_2 \; \{Q\} }{\varnothing \vdash \{P\} \; \text{if} \; B \; \text{then} \; C_1 \; \text{else} \; C_2 \; \{Q\} }
\]

**Backwards reasoning proof rules**

\[
\frac{\varnothing \vdash P \Rightarrow Q }{\varnothing \vdash \{P\} \; \text{skip} \; \{Q\} }
\]

\[
\frac{\varnothing \vdash (P \land B) \; C_1 \; \{Q\} \; \{P \land \neg B\} \; C_2 \; \{Q\} }{\varnothing \vdash \{P\} \; \text{if} \; B \; \text{then} \; C_1 \; \text{else} \; C_2 \; \{Q\} }
\]

There is no separate rule of consequence anymore. This set of rules is still relatively complete.
Finding proofs: loop invariants

Finding proofs: factorial

Specifying a program computing factorial

We wish to verify that the following command computes the factorial of $X$, and stores the result in $Y$:

\[
\textbf{while } X \neq 0 \textbf{ do } (Y := Y \times X; X := X - 1)
\]

First, we need to formalise the specification:

- Factorial is only defined for non-negative numbers, so $X$ should be non-negative in the initial state.
- The terminal state of $Y$ should be equal to the factorial of the initial state of $X$.
- The implementation assumes that $Y$ is equal to 1 initially.

A specification of a program computing factorial

This corresponds to the following partial correctness triple:

\[
\{X = x \land X \geq 0 \land Y = 1\} \\
\textbf{while } X \neq 0 \textbf{ do } (Y := Y \times X; X := X - 1) \\
\{Y = x!\}
\]

Here, ‘!’ denotes the usual mathematical factorial function.

Note that we used an auxiliary variable $x$ to record the initial value of $X$ and relate the terminal value of $Y$ with the initial value of $X$. 
How does one find an invariant?

\[ \vdash P \Rightarrow I \quad \vdash \{ I \land B \} \ C \ \{ I \} \quad \vdash I \land \neg B \Rightarrow Q \]

\[ \vdash \{ P \} \text{ while } B \text{ do } C \ \{ Q \} \]

Here, \( I \) is an invariant, meaning that it

- must hold initially;
- must be preserved by the loop body when \( B \) is true; and
- must imply the desired postcondition when \( B \) is false.

Analysing the factorial implementation

\[ \{ X = x \land X \geq 0 \land Y = 1 \} \]

\[ \text{while } X \neq 0 \text{ do } (Y := Y \times X; X := X - 1) \]

\[ \{ Y = x! \} \]

How does this program work?

Observations about the factorial implementation

\[ \{ X = x \land X \geq 0 \land Y = 1 \} \]

\[ \text{while } X \neq 0 \text{ do } (Y := Y \times X; X := X - 1) \]

\[ \{ Y = x! \} \]

An invariant for the factorial implementation

\[ \{ X = x \land X \geq 0 \land Y = 1 \} \]

\[ \text{while } X \neq 0 \text{ do } (Y := Y \times X; X := X - 1) \]

\[ \{ Y = x! \} \]

Take \( I \) to be \( Y \times X! = x! \land X \geq 0 \).

(We need \( X \geq 0 \) for \( X! \) to make sense.)

\( Y \) is the value computed so far, and \( X! \) remains to be computed.
Backwards reasoning proof rules (recap)

\[\vdash P \Rightarrow Q\]
\[\vdash \{P\} \text{skip} \{Q\}\]
\[\vdash \{P\} C_1 \{R\} \vdash \{R\} C_2 \{Q\}\]
\[\vdash \{P\} \vdash \{P\} C_1; C_2 \{Q\}\]
\[\vdash P \Rightarrow Q\]
\[\vdash \{P\} \text{if } B \text{ then } C_1 \text{ else } C_2 \{Q\}\]

Derivation tree of the verified factorial

\[\vdash (X=x \land X \geq 0 \land Y=1) \Rightarrow (Y \times X! = x! \land X \geq 0)\]
\[\vdash (Y \times X! = x! \land X \geq 0 \land X \neq 0) \Rightarrow ((Y \times X! \ldots 0} Y:=Y \times X; X:=X−1{Y \times X! = x! \land X \geq 0} \]
\[\vdash (Y \times X! = x! \land X \geq 0 \land \neg (X \neq 0)) \Rightarrow Y=x!\]

Proof outlines

Derivations in Hoare logic are often more readable when given as proof outlines instead of proof trees.

Proof outlines are code listings annotated with Hoare logic assertions between statements.

Sequences of Hoare logic assertions indicate reasoning about assertions.
Proof outline for the implementation of factorial

\{ X = x \land X \geq 0 \land Y = 1 \} \\
\{ Y \times X! = x! \land X \geq 0 \} \\
\textbf{while } X \neq 0 \textbf{ do} \\
(\{ Y \times X! = x! \land X \geq 0 \land X \neq 0 \} \\
\{ (Y \times X) \times (X - 1)! = x! \land (X - 1) \geq 0 \} \\
Y := Y \times X; \\
\{ Y \times (X - 1)! = x! \land (X - 1) \geq 0 \} \\
X := X - 1 \\
\{ Y \times X! = x! \land X \geq 0 \}) \\
\{ Y \times X! = x! \land X \geq 0 \land \neg(X \neq 0) \} \\
\{ Y = x! \}

Finding proofs: Fibonacci

A verified Fibonacci implementation

We wish to verify that the following command computes the \(N\)-th Fibonacci number (indexed from 1), and stores the result in \(Y\). This corresponds to the following partial correctness Hoare triple:

\{ 1 \leq N \land N = n \} \\
X = 0; \\
Y := 1; \\
Z := 1; \\
\textbf{while } Z < N \textbf{ do} \\
(\{ Y := X + Y; X := Y - X; Z := Z + 1 \} \\
\{ Y = \text{fib}(n) \})

Recall that the Fibonacci sequence is defined by

\( \text{fib}(1) = 1, \quad \text{fib}(2) = 1, \quad \forall n > 2. \text{fib}(n) = \text{fib}(n - 1) + \text{fib}(n - 2) \)

Moreover, for convenience, we assume \( \text{fib}(0) = 0 \).
Observations about the implementation of Fibonacci

\{X = 0 \land Y = 1 \land Z = 1 \land 1 \leq N \land N = n\}

while \(Z < N\) do

\((Y := X + Y; X := Y - X; Z := Z + 1)\)

\{Y = \text{fib}(n)\}

<table>
<thead>
<tr>
<th>iteration</th>
<th>0</th>
<th>1</th>
<th>2</th>
<th>3</th>
<th>4</th>
<th>5</th>
<th>6</th>
<th>\cdots</th>
<th>n - 1</th>
</tr>
</thead>
<tbody>
<tr>
<td>(Y)</td>
<td>1</td>
<td>1</td>
<td>2</td>
<td>3</td>
<td>5</td>
<td>8</td>
<td>13</td>
<td>\cdots</td>
<td>\text{fib}(n)</td>
</tr>
<tr>
<td>(X)</td>
<td>0</td>
<td>1</td>
<td>1</td>
<td>2</td>
<td>3</td>
<td>5</td>
<td>8</td>
<td>\cdots</td>
<td>\text{fib}(n - 1)</td>
</tr>
<tr>
<td>(Z)</td>
<td>1</td>
<td>2</td>
<td>3</td>
<td>4</td>

</tr>
</tbody>
</table>

Analysing the implementation of Fibonacci

\{X = 0 \land Y = 1 \land Z = 1 \land 1 \leq N \land N = n\}

while \(Z < N\) do

\((Y := X + Y; X := Y - X; Z := Z + 1)\)

\{Y = \text{fib}(n)\}

\(Z\) is used to count loop iterations, and \(Y\) and \(X\) are used to compute the Fibonacci number:

\(Y\) contains the current Fibonacci number,

and \(X\) contains the previous Fibonacci number.

This suggests trying the invariant

\(Y = \text{fib}(Z) \land X = \text{fib}(Z - 1) \land Z > 0\).

(We need \(Z > 0\) for \(\text{fib}(Z - 1)\) to make sense.)

A better invariant for the Fibonacci implementation

\{X = 0 \land Y = 1 \land Z = 1 \land 1 \leq N \land N = n\}

while \(Z < N\) do

\((Y := X + Y; X := Y - X; Z := Z + 1)\)

\{Y = \text{fib}(n)\}

While \(Y = \text{fib}(Z) \land X = \text{fib}(Z - 1) \land Z > 0\) is an invariant,

it is not strong enough to establish the desired postcondition.

We need to know that when the loop terminates, then \(Z = n\).

It suffices to strengthen the invariant to:

\(Y = \text{fib}(Z) \land X = \text{fib}(Z - 1) \land Z > 0 \land Z \leq N \land N = n\)
Proof outline for the loop of the Fibonacci implementation

\[ X = 0 \land Y = 1 \land Z = 1 \land 1 \leq N \land N = n \]
\[ Y = fib(Z) \land X = fib(Z - 1) \land Z > 0 \land Z \leq N \land N = n \]

while \( Z < N \) do

\( \{ Y = fib(Z) \land X = fib(Z - 1) \land Z > 0 \land Z \leq N \land N = n \} \)
\( Y := fib(Z) \land X = fib(Z - 1) \land Z > 0 \land Z \leq N \land N = n \)
\( X := Y - X; \)
\( Y := X + Y; \)
\( Y := fib(Z + 1) \land X = fib(Z) \land Z + 1 > 0 \land Z + 1 \leq N \land N = n \)
\( Z := Z + 1 \)
\( Y := fib(Z) \land X = fib(Z - 1) \land Z > 0 \land Z \leq N \land N = n \)
\( \{ Y = fib(n) \} \)

Verification condition generation

Finding invariants is difficult (as we will see in the next lecture).

However, we can write a simple recursive function \( VC \) that takes a precondition \( P \), an annotated program \( C \) in which loop invariants are provided as annotations, and a postcondition and \( Q \), and returns a set of assertions (called “verification conditions”) such that, if they all hold, then \( \{ P \} \mid C \mid \{ Q \} \) holds (where \( \mid C \mid \) is \( C \) without the annotations).

Formally,

\[ \forall C, P, Q. (\forall \phi \in VC(P, C, Q). \vdash \phi) \Rightarrow (\vdash \{ P \} \mid C \mid \{ Q \}) \]
Summary of proof-finding

We have looked at how to find proofs:

• how “backwards” reasoning can help;
• how to find invariants.

Finding invariants is difficult!

Writing out full proof trees or even proof outlines by hand is tedious and error-prone, even for simple programs. However, the trivia can be mechanised, leaving only finding invariants and proving difficult implications to the user.

In the next lecture, we will formalise the intuitions we gave in the first lecture, and prove soundness of Hoare logic.

Recap

In the previous lecture, we specified and verified some small programs using the intuitions and syntactic rules of Hoare logic we introduced in the first lecture.

In this lecture, we will put these intuitions on a formal grounding, and prove the soundness of the syntactic rules we used.
Semantics of Hoare logic

Recall: to define a Hoare logic, we need four main components:

• the programming language that we want to reason about:
  its syntax and dynamic semantics;
• an assertion language for defining state predicates:
  its syntax and an interpretation;
• an interpretation of Hoare triples;
• a (sound) syntactic proof system for deriving Hoare triples.

This lecture defines a formal semantics of Hoare logic, and introduces properties of Hoare logic (soundness & completeness).

Dynamic semantics of WHILE

The dynamic semantics of WHILE will be given in the form of a small-step operational semantics (as in Part IB Semantics).

The states of the small-step operational semantics, called configurations, are pairs of a command $C$ and a stack $s$. We will abuse terminology, and also refer to $s$ as the state.

The step relation $\langle C, s \rangle \rightarrow \langle C', s' \rangle$ expresses that configuration $\langle C, s \rangle$ can take a small step to become configuration $\langle C', s' \rangle$.

We will write $\rightarrow^*$ for the reflexive, transitive closure of $\rightarrow$.

Stacks are functions from variables to integers:

$$s \in \text{Stack} \defeq \text{Var} \rightarrow \mathbb{Z}$$

These are total functions, and define the current value of every program variable and auxiliary variable.

This models WHILE with arbitrary precision integer arithmetic. A more realistic model might use 32-bit integers and require reasoning about overflow, etc.
Dynamic semantics of expressions: first approach

We could have two small-step reduction relations for arithmetic expressions and boolean expressions, \( \langle E, s \rangle \rightarrow \langle E', s' \rangle \) and \( \langle B, s \rangle \rightarrow \langle B', s' \rangle \):

- \( \langle X, s \rangle \rightarrow \langle s(X), s \rangle \)
- \( \langle E_1, s \rangle \rightarrow \langle E'_1, s' \rangle \)
- \( \langle E_1 + E_2, s \rangle \rightarrow \langle E'_1 + E'_2, s' \rangle \)

\( N_1 + N_2 = N \quad \langle N_1 + N_2, s \rangle \rightarrow \langle N, s \rangle \)

\( E \) evaluates arithmetic expression \( E \) to an integer in stack \( s \):

\[ E[\[−\]](s) \text{ evaluates } E \text{ with } = \]

\[ E[\[N\]](s) \overset{def}{=} N \]

\[ E[\[X\]](s) \overset{def}{=} s(X) \]

\[ E[\[E_1 + E_2\]](s) \overset{def}{=} E[\[E_1\]](s) + E[\[E_2\]](s) \]

\[ E[\[X + 2\]](s) = E[\[X\]](s) + E[\[2\]](s) = 3 + 2 = 5, \text{ and} \]

\[ E[\[Y + 4\]](s) = E[\[Y\]](s) + E[\[4\]](s) = 0 + 4 = 4. \]

Dynamic semantics of expressions: our approach

However, expressions in \textsc{while} do not change the stack, and do not get stuck:

\[ \forall E, s. \ \exists N. \ \langle E, s \rangle \rightarrow^* \langle N, s \rangle \]

We take advantage of this, and specify the dynamic semantics of expressions in a way which makes our setup easier (the results are the same, but execution can take fewer steps):

We use functions \( E[s] \) and \( B[B](s) \) to evaluate arithmetic expressions and boolean expressions in a given stack \( s \), respectively.

Semantics of boolean expressions

\( B[B](s) \) evaluates boolean expression \( B \) to a boolean in stack \( s \):

\[ B[\[-\]](=) : BExp \times Stack \rightarrow \mathbb{B} \]

\[ B[\[N\]](s) \overset{def}{=} \top \]

\[ B[\[X\]](s) \overset{def}{=} \bot \]

\[ B[\[E_1 \leq E_2\]](s) \overset{def}{=} \begin{cases} \top & \text{if } E[\[E_1\]](s) \leq E[\[E_2\]](s) \\ \bot & \text{otherwise} \end{cases} \]

\( B[\[X + 2 \geq Y + 4\]](s) = E[\[X + 2\]](s) \geq E[\[Y + 4\]](s) = 5 \geq 4 = \top. \)
Small-step operational semantics of WHILE

\[ E[s] = N \]
\[ \langle X := E, s \rangle \rightarrow \langle \text{skip}, s[X \mapsto N] \rangle \]
\[ \langle \text{skip}, C_2, s \rangle \rightarrow \langle C_2, s \rangle \]
\[ \langle C_1, s \rangle \rightarrow \langle C_1', s' \rangle \]
\[ \langle C_1; C_2, s \rangle \rightarrow \langle C_1', C_2', s' \rangle \]

\[ B[s] = \top \]
\[ \langle \text{if } B \text{ then } C_1 \text{ else } C_2, s \rangle \rightarrow \langle C_1, s \rangle \]
\[ \langle \text{if } B \text{ then } C_1 \text{ else } C_2, s \rangle \rightarrow \langle C_2, s \rangle \]
\[ B[s] = \bot \]
\[ \langle \text{while } B \text{ do } C, s \rangle \rightarrow \langle \text{skip}, s \rangle \]
\[ B[s] = \top \]
\[ \langle \text{while } B \text{ do } C, s \rangle \rightarrow \langle C; \text{while } B \text{ do } C, s \rangle \]

Properties of WHILE

Safety and determinacy

A configuration \( \langle C, s \rangle \) is stuck, written \( \langle C, s' \rangle \not\rightarrow \), when \( \forall C', s'. \neg(\langle C, s \rangle \rightarrow \langle C', s' \rangle) \).

The dynamic semantics of WHILE is safe, in that a configuration is stuck exactly when its command is \text{skip}:

\[ (\langle C, s \rangle \not\rightarrow) \iff C = \text{skip} \]

This is true for any syntactically well-formed command, without any further typing! (Because our language is very simple.)

The dynamic semantics of WHILE is deterministic:

\[ \langle C, s \rangle \rightarrow \langle C', s' \rangle \land \langle C, s \rangle \rightarrow \langle C'', s'' \rangle \Rightarrow C'' = C' \land s'' = s' \]

Non-termination

It is possible to have an infinite sequence of steps starting from a configuration \( \langle C, s \rangle \): \( \langle C, s \rangle \) has a non-terminating execution (also “can diverge”), written \( \langle C, s \rangle \rightarrow^\omega \), when there exists a sequence of commands \( (C_n)_{n \in \mathbb{N}} \) and a sequence of stacks \( (s_n)_{n \in \mathbb{N}} \) such that

\[ C_0 = C \land s_0 = s \land \forall n \in \mathbb{N}. \langle C_n, s_n \rangle \rightarrow \langle C_{n+1}, s_{n+1} \rangle \]

Note that

\[ \langle C, s \rangle \rightarrow^\omega \iff \exists C', s'. \langle C, s \rangle \rightarrow \langle C', s' \rangle \land \langle C', s' \rangle \rightarrow^\omega \]

Because WHILE is safe and deterministic, a configuration can take steps to \text{skip} if and only if it does not diverge:

\[ (\exists s'. \langle C, s \rangle \rightarrow^* \langle \text{skip}, s' \rangle) \iff \neg(\langle C, s \rangle \rightarrow^\omega) \]

This can break down with a non-deterministic language.
Substitution

We use $E_1[E_2/X]$ to denote $E_1$ with $E_2$ substituted for every occurrence of program variable $X$:

$$-[= / \equiv] : \text{Expr} \times \text{Expr} \times \text{Var} \to \text{Expr}$$

$N[E_2/X] \overset{\text{def}}{=} N$

$Y[E_2/X] \overset{\text{def}}{=} \begin{cases} Y & \text{if } Y = X \text{ and } E_2 \\ Y & \text{if } Y \neq X \text{ and } Y \\ (E_a + E_b)[E_2/X] \overset{\text{def}}{=} (E_a[E_2/X]) + (E_b[E_2/X]) \\ \vdots \end{cases}$

For example, $(X + (Y \times 2))[3 + Z/Y] = X + ((3 + Z) \times 2)$.

Proof of substitution property: variable case

$$E[E_1[E_2/X]](s) = E[E_1](s[X \mapsto E[E_2](s)])$$

Case $E_1 \equiv Y$:

$$E[Y[E_2/X]](s) = \begin{cases} E[X[E_2/X]](s) = E[E_2](s) = E[X](s[X \mapsto E[E_2](s)]) \\ E[Y](s) = E[Y](s[X \mapsto E[E_2](s)]) \\ E[Y](s[X \mapsto E[E_2](s)]) \\ \end{cases}$$

Proof of substitution property: addition case

$$E[E_1[E_2/X]](s) = E[E_1](s[X \mapsto E[E_2](s)])$$

Case $E_1 \equiv E_a + E_b$:

$$E[(E_a + E_b)[E_2/X]](s) = E[E_a[E_2/X]](s) + E[E_b[E_2/X]](s) = E[E_a](s[X \mapsto E[E_2](s)]) + E[E_b](s[X \mapsto E[E_2](s)]) = E[E_a + E_b](s[X \mapsto E[E_2](s)])$$

Substitution property for expressions

We will use the following expression substitution property later:

$$E[E_1[E_2/X]](s) = E[E_1](s[X \mapsto E[E_2](s)])$$

The expression substitution property follows by induction on $E_1$. Case $E_1 \equiv N$:

$$E[N[E_2/X]](s) = E[N](s) = N = E[N](s[X \mapsto E[E_2](s)])$$
Now, we have formally defined the dynamic semantics of the \textsc{while} language that we wish to reason about.

The next step is to formalise the assertion language that we will use to describe and reason about states of \textsc{while} programs.

We take the language of assertions to be (slight variation of) an instance of single-sorted first-order logic with equality (as in Part IB Logic and Proof).

The formal syntax of the assertion language is given below:

\[
\begin{align*}
\chi & ::= X | x & \text{variables} \\
t & ::= \chi | f(t_1, \ldots, t_n) & \text{terms} \\
P, Q & ::= \bot | T | P \land Q | P \lor Q | P \Rightarrow Q & \text{assertions} \\
\neg P & ::= P \Rightarrow \bot
\end{align*}
\]

Quantifiers quantify over terms, and only bind logical variables.

Here \( f \) and \( p \) range over an unspecified set of function symbols and predicate symbols, respectively, that includes (symbols for) the usual mathematical functions and predicates on integers.

In particular, we assume that they contain symbols that allows us to embed arithmetic expressions \( E \) as terms, and boolean expressions \( B \) as assertions.

\[ [\chi](s) \overset{def}{=} s(\chi) \]
\[ [f(t_1, \ldots, t_n)](s) \overset{def}{=} [f([t_1](s), \ldots, [t_n](s)) \]

We assume that the appropriate function \([f]\) associated to each function symbol \( f \) is provided along with the implicit signature.

In particular, we have \([E](s) = \mathcal{E}[E](s)\).
Semantics of assertions

The term and assertion semantics satisfy a similar substitution property to the expression semantics:

- \[ [t[ E / X ]] (s) = [t]([X ← E](s))] \]

- \[ s \in [P[E/X]] \iff s[X \mapsto E](s) \in [P] \]

They are easily provable by induction on \( t \) and \( P \), respectively: the former by using the substitution property for expressions, and the latter by using the former. (Exercise)

The latter property will be useful in the proof of soundness of the syntactic assignment rule.

Substitutions

We use \( t[E/X] \) and \( P[E/X] \) to denote \( t \) and \( P \) with \( E \) substituted for every occurrence of program variable \( X \), respectively.

Since our quantifiers bind logical variables, and all free variables in \( E \) are program variables, there is no issue with variable capture:

\[
(\forall x. P)[E/X] \overset{\text{def}}{=} \forall x. (P[E/X])
\]
Semantics of Hoare logic

Now that we have formally defined the dynamic semantics of WHILE and our assertion language, we can define the formal meaning of our triples.

A partial correctness triple asserts that if the given command terminates when executed from an initial state that satisfies the precondition, then the terminal state must satisfy the postcondition:

\[ \models \{ P \} \ C \ \{ Q \} \quad \overset{\text{def}}{=} \quad \forall s, s'. s \in [P] \land \langle C, s \rangle \rightarrow^* \langle \text{skip}, s' \rangle \Rightarrow s' \in [Q] \]

Without safety, we would have to worry about getting stuck without reaching \text{skip}.

Properties of Hoare logic

Now, we have a syntactic proof system for deriving Hoare triples, \( \vdash \{ P \} \ C \ \{ Q \} \), and a formal definition of the meaning of our Hoare triples, \( \models \{ P \} \ C \ \{ Q \} \).

How are these related?

We might hope that any triple that can be derived syntactically holds semantically (soundness), and that any triple that holds semantically is syntactically derivable (completeness).

Hoare logic is sound but \textbf{not} complete.
Soundness of Hoare logic

**Theorem (Soundness)**

If \( \vdash \{ P \} C \{ Q \} \) then \( \models \{ P \} C \{ Q \} \).

Soundness expresses that any triple derivable using the syntactic proof system holds semantically.

Soundness can be proved by induction on the \( \vdash \{ P \} C \{ Q \} \) derivation:

- it suffices to show, for each inference rule, that if each hypothesis holds semantically, then the conclusion holds semantically.

**Soundness of the assignment rule**

\[ \models \{ P[E/X] \} X := E \{ P \} \]

Assume \( s \in \llbracket P[E/X] \rrbracket \) and \( \langle X := E, s \rangle \to^* \langle \text{skip}, s' \rangle \).

From the substitution property, it follows that
\( s[X \mapsto \mathcal{E}[E](s)] \in \llbracket P \rrbracket \).

From inversion on the steps, there exists an \( N \) such that
\( \mathcal{E}[E](s) = N \) and \( s' = s[X \mapsto N] \), so \( s' = s[X \mapsto \mathcal{E}[E](s)] \).

Hence, \( s' \in \llbracket P \rrbracket \).

**Soundness of the loop rule**

If \( \models \{ P \land B \} C \{ P \} \) then \( \models \{ P \} \textbf{while } B \textbf{ do } C \{ P \land \neg B \} \)

How can we get past the fact that the loop step rule defines the steps of a loop in terms of the steps of a loop?

We will prove \( \models \{ P \} \textbf{while } B \textbf{ do } C \{ P \land \neg B \} \) by proving a modified version of the property.

We write \( \langle C, s \rangle \to^k \langle C', s' \rangle \) to mean \( \langle C, s \rangle \) can take \( k \) steps, where \( k \geq 0 \), to reach \( \langle C', s' \rangle \).
Soundness of the loop rule: base case

If (IH) \( \forall s, s'. s \in [P \land B] \land (C, s) \Rightarrow^* (\text{skip}, s') \Rightarrow s' \in [P] \), then \( \forall n > 0. \forall k < n. \forall s, s'. s \in [P] \land (\text{while } B \text{ do } C, s) \Rightarrow^k (\text{skip}, s') \Rightarrow s' \in [P \land \neg B] \).

We can prove this by a (nested) induction on \( n \):

Case 1: assume \( s \in [P] \), \( k < 1 \), and
\( (\text{while } B \text{ do } C, s) \Rightarrow^k (\text{skip}, s') \).

Then \( \text{while } B \text{ do } C = \text{skip} \), so we have a contradiction.

Soundness of the loop rule: inductive case

If (IH) \( \forall s, s'. s \in [P \land B] \land (C, s) \Rightarrow^* (\text{skip}, s') \Rightarrow s' \in [P] \), then \( \forall n > 0. \forall k < n. \forall s, s'. s \in [P] \land (\text{while } B \text{ do } C, s) \Rightarrow^k (\text{skip}, s') \Rightarrow s' \in [P \land \neg B] \).

Case \( n + 1 \): assume \( s \in [P] \), \( k < n + 1 \),
\( (\text{while } B \text{ do } C, s) \Rightarrow^k (\text{skip}, s') \), and
\( (\text{nIH}) \forall k < n. \forall s, s'. s \in [P] \land (\text{while } B \text{ do } C, s) \Rightarrow^k (\text{skip}, s') \Rightarrow s' \in [P \land \neg B] \).

If \( k = 1 \), \( B \) must have evaluated to false: \( B[B](s) = \bot \) and \( s' = s \).
Since \( B[B](s) = \bot \), \( s \notin [B] \), so \( s \notin [B \Rightarrow \bot] \), so \( s \in [B \Rightarrow \bot] \), so \( s \in [\bot] \). Therefore, \( s \in [P \land \neg B] \).
Hence, \( s' = s \in [P \land \neg B] \).

Other properties of Hoare logic
Completeness

Completeness is the converse property of soundness: If $\models \{P\} C \{Q\}$ then $\vdash \{P\} C \{Q\}$.

Our Hoare logic inherits the incompleteness of arithmetic and is therefore not complete.

Relative completeness

The previous argument showed that because the assertion logic is not complete, then neither is Hoare logic.

However, Hoare logic is relatively complete for our simple language:

- Relative completeness expresses that any failure to derive $\vdash \{P\} C \{Q\}$ for a statement that holds semantically can be traced back to a failure to prove $\vdash R$ for some valid arithmetic statement $R$.

In practice, completeness is not that important, and there is more focus on nice, usable rules.

Decidability

Finally, Hoare logic is not decidable.

$\models \{\top\} C \{\bot\}$ holds if and only if $C$ does not terminate.

Moreover, we can encode Turing machines in WHILE.

Hence, since the Halting problem is undecidable, so is Hoare logic.
Other perspectives on Hoare triples

So far, we have assumed $P$, $C$, and $Q$ were given, and focused on proving $\vdash \{P\} C \{Q\}$.

Recall, if $P$ and $Q$ are assertions, $P$ is stronger than $Q$, and $Q$ is weaker than $P$, when $P \Rightarrow Q$.

If we are given $P$ and $C$, can we infer a $Q$? Is there a best such $Q$, $sp(P, C)$? (‘strongest postcondition’)

Symmetrically, if we are given $C$ and $Q$, can we infer a $P$? Is there a best such $P$, $wlp(C, Q)$? (‘weakest liberal precondition’)

Are there functions $wlp$ and $sp$ such that
\[
(\vdash P \Rightarrow wlp(C, Q)) \iff \vdash \{P\} C \{Q\} \iff (\vdash sp(P, C) \Rightarrow Q)
\]

Terminology

We write $wlp$ and talk about weakest liberal precondition because we only consider partial correctness.

This has no relevance here because, as we will see, there is no effective general finite (first-order) formula for weakest preconditions, liberal or not, or strongest postconditions, for commands containing loops, so we will not consider weakest preconditions, liberal or not, for loops, so there is no difference between partial and total correctness.

Computing weakest liberal preconditions (except for loops)

Dijkstra gives rules for computing weakest liberal preconditions for deterministic loop-free code:
\[
wlp(skip, Q) = Q \\
wlp(X := E, Q) = Q[E/X] \\
wlp(C_1; C_2, Q) = wlp(C_1, wlp(C_2, Q)) \\
wlp(if B then C_1 else C_2, Q) = (B \Rightarrow wlp(C_1, Q)) \land (\neg B \Rightarrow wlp(C_2, Q))
\]

These rules are suggested by the relative completeness of the Hoare logic proof rules from the first lecture.
Example of weakest liberal precondition computation

\[ wlp(X := X + 1; Y := Y + X, \exists m, n. X = 2 \times m \land Y = 2 \times n) = wlp(X := X + 1, wlp(Y := Y + X, \exists m, n. X = 2 \times m \land Y = 2 \times n)) = wlp(X := X + 1, (\exists m, n. X = 2 \times m \land Y = 2 \times n)[Y + X/Y]) = (\exists m, n. X = 2 \times m \land Y + X = 2 \times n) = (\exists m, n. X = 2 \times m \land Y = 2 \times n)\]
\[ \Leftrightarrow (\exists m, n. X = 2 \times m + 1 \land Y = 2 \times n) \]

Weakest preconditions for loops

While the following property holds for loops
\[ wlp(while B do C, Q) \Leftrightarrow wlp(if B then (C; while B do C) else skip, Q) \Leftrightarrow (B \Rightarrow wlp(C, wlp(while B do C, Q))) \land (\neg B \Rightarrow Q) \]
it does not define \( wlp(while B do C, Q) \) as a finite formula in first-order logic.

There is no general finite formula for \( wlp(while B do C, Q) \) in first-order logic. (Otherwise, it would be easy to find invariants!)

Verification condition generation

We can now sketch the design of a verification generation algorithm.

(1) The precondition needs to imply the approximate weakest liberal precondition induced by the provided loop invariants.

(2) Moreover, the provided loop invariants need to be actual loop invariants, and, together with the guard not holding, need to imply the loop postcondition.

\[
\begin{align*}
\vdash P &\Rightarrow I & \vdash \{I \land B\} C \{I\} & \vdash I \land \neg B \Rightarrow Q \\
\vdash \{P\} while B do C \{Q\} &
\end{align*}
\]
These can be computed mutually recursively.

Summary

We have defined a dynamic semantics for the WHILE language, and a formal semantics for a Hoare logic for WHILE.

We have shown that the syntactic proof system from the first lecture is sound with respect to this semantics, but not complete.

Supplementary reading on soundness and completeness:
- Software Foundations, Benjamin C. Pierce et al.

In the next lecture, we will look at extending Hoare logic to reason about pointers.
We can define annotated programs:

\[ C ::= \text{skip} \]
\[ | \ C_1; C_2 \]
\[ | X := E \]
\[ | \text{if } B \text{ then } C_1 \text{ else } C_2 \]
\[ | \text{while } B \text{ do } \{ I \} C \]

and an erasure function:

\[ |\text{skip}| \overset{\text{def}}{=} \text{skip} \]
\[ |C_1; C_2| \overset{\text{def}}{=} |C_1|; |C_2| \]
\[ |X := E| \overset{\text{def}}{=} X := E \]
\[ |\text{if } B \text{ then } C_1 \text{ else } C_2| \overset{\text{def}}{=} |\text{if } B \text{ then } |C_1| \text{ else } |C_2| | \]
\[ |\text{while } B \text{ do } \{ I \} C| \overset{\text{def}}{=} |\text{while } B \text{ do } |C| | \]

(2) an auxiliary function that collects side-conditions of loops:

\[ \text{VCaux}(\text{skip}, Q) \overset{\text{def}}{=} \emptyset \]
\[ \text{VCaux}(X := E, Q) \overset{\text{def}}{=} \emptyset \]
\[ \text{VCaux}(\text{if } B \text{ then } C_1 \text{ else } C_2, Q) \overset{\text{def}}{=} \text{VCaux}(C_1, Q) \cup \text{VCaux}(C_2, Q) \]
\[ \text{VCaux}(C_1; C_2) \overset{\text{def}}{=} \text{VCaux}(C_1, \text{awlp}(C_2, Q)) \cup \text{VCaux}(C_2, Q) \]
\[ \text{VCaux}(\text{while } B \text{ do } \{ I \} C, Q) \overset{\text{def}}{=} \{ I \land \neg B \Rightarrow Q, I \land B \Rightarrow \text{awlp}(C, I) \} \cup \text{VCaux}(C, I) \]
Recap

In the previous lectures, we have considered a language, WHILE, where mutability only concerned program variables.

In this lecture, we will extend the WHILE language with pointer operations on a heap, and look at the challenges Hoare logic faces when trying to reason about this language.

This will motivate introducing an extension of Hoare logic, called separation logic, to enable practical reasoning about pointers.

Syntax of WHILE\(_p\), a language with pointers

We introduce new commands to manipulate the heap:

\[
E ::= N \mid X \mid E_1 + E_2 \quad \text{arithmetic expressions} \\
\quad \mid E_1 - E_2 \mid E_1 \times E_2 \mid \cdots \\
\text{null} \equiv 0
\]

\[
B ::= T \mid F \mid E_1 = E_2 \quad \text{boolean expressions} \\
\quad \mid E_1 \leq E_2 \mid E_1 \geq E_2 \mid \cdots
\]

\[
C ::= \text{skip} \mid C_1; C_2 \mid X := E \quad \text{commands} \\
\quad \mid \text{if } B \text{ then } C_1 \text{ else } C_2 \\
\quad \mid \text{while } B \text{ do } C \\
\quad \mid X := [E] \mid [E_1] := E_2 \\
\quad \mid X := \text{alloc}(E_0, \ldots, E_n) \\
\quad \mid \text{dispose}(E)
\]

The heap

Commands are now evaluated also with respect to a heap that stores the current values of allocated locations.

Heap assignment, dereferencing, and deallocation fail if the given locations are not currently allocated.

This is a design choice that makes WHILE\(_p\) more like a programming language, whereas having a heap with all locations always allocated would make WHILE\(_p\) more like assembly.

It allows us to consider faults, and how separation logic can be used to prevent faults, and it also makes things clearer.
Heap usage commands

Heap assignment command \([E_1] := E_2\)
- evaluates \(E_1\) to a location \(\ell\) and \(E_2\) to a value \(N\), and updates the heap to map \(\ell\) to \(N\); faults if \(\ell\) is not currently allocated.

Heap dereferencing command \(X := [E]\)
- evaluates \(E\) to a location \(\ell\), and assigns the value that \(\ell\) maps to to \(X\); faults if \(\ell\) is not currently allocated.

We could have heap dereferencing be an expression, but then expressions would fault, which would add complexity.

Heap management commands

Allocation assignment command: \(X := \text{alloc}(E_0, \ldots, E_n)\)
- chooses \(n + 1\) consecutive unallocated locations starting at location \(\ell\), evaluates \(E_0, \ldots, E_n\) to values \(N_0, \ldots, N_n\), updates the heap to map \(\ell + i\) to \(N_i\) for each \(i\), and assigns \(\ell\) to \(X\).

In \(\text{WHILE}_p\), allocation never faults.
A real machine would run out of memory at some point.

Deallocation command \(\text{dispose}(E)\)
- evaluates \(E\) to a location \(\ell\), and deallocates location \(\ell\) from the heap; faults if \(\ell\) is not currently allocated.

Pointers

\(\text{WHILE}_p\) has proper pointer operations, as opposed for example to references:
- pointers can be invalid: \(X := [\text{null}]\) faults
- we can perform pointer arithmetic:
  - \(X := \text{alloc}(0, 1); Y := [X + 1]\)
  - \(X := \text{alloc}(0); \text{if } X = 3 \text{ then } [3] := 1 \text{ else } [X] := 2\)

We do not have a separate type of pointers: we use integers as pointers.

Pointers in C have many more subtleties. For example, in C, pointers can point to the stack.

Pointers and data structures

In \(\text{WHILE}_p\), we can encode data structures in the heap. For example, we can encode the mathematical list \([12, 99, 37]\) with the following singly-linked list:

\[
\begin{array}{c}
\text{HEAD} \rightarrow 12 \rightarrow 99 \rightarrow 37 \rightarrow X
\end{array}
\]

In \(\text{WHILE}\), we would have had to encode that in integers, for example as \(\text{HEAD} = 2^{12} \times 3^{99} \times 5^{37}\) (as in Part IB Computation theory).

More concretely:

\[
\begin{array}{c}
\text{HEAD} = 10 \rightarrow 0 \rightarrow 7 \rightarrow 8 \rightarrow 10 \rightarrow 11 \rightarrow 121 \rightarrow 12 \rightarrow 7 \rightarrow 37 \rightarrow 0
\end{array}
\]
Operations on mutable data structures

For instance, this operation deletes the first element of the list:

\[
X := [\text{HEAD} + 1]; \quad \text{// lookup address of second element}
\]
\[
\text{dispose}(\text{HEAD}); \quad \text{// deallocate first element}
\]
\[
\text{dispose}(\text{HEAD} + 1);
\]
\[
\text{HEAD} := X \quad \text{// swing head to point to second element}
\]

States of WHILE\(_p\)

For the WHILE language, we modelled the state as a stack, that is, a function mapping program variables to values (integers):

\[
s \in \text{Stack} \equiv \text{Var} \rightarrow \mathbb{Z}
\]

For WHILE\(_p\), we extend the state to be composed of a stack and a heap, where

\begin{itemize}
  \item the stack maps program variables to values (as before), and
  \item the heap maps allocated locations to values.
\end{itemize}

We have

\[
\text{State} \equiv \text{Stack} \times \text{Heap}
\]

Heaps

We elect for locations to be non-negative integers:

\[
\ell \in \text{Loc} \equiv \{\ell \in \mathbb{Z} \mid 0 \leq \ell\}
\]

null is a location, but a “bad” one, that is never allocated.

To model the fact that only a finite number of locations is allocated at any given time, we model the heap as a finite function, that is, a partial function with a finite domain:

\[
h \in \text{Heap} \equiv (\text{Loc} \setminus \{\text{null}\})^{\text{fin}} \rightarrow \mathbb{Z}
\]
Adapting the base constructs to handle the heap

The base constructs can be adapted to handle the extended state and failure in the expected way:

\[
\begin{align*}
E[X \leftarrow E_1,\langle s,h \rangle] & \rightarrow \langle s[N], h \rangle \\
E[X \leftarrow E_1,\langle s,h \rangle] & \rightarrow \langle E_2, \langle s, h \rangle \rangle \\
B & \rightarrow E_1 \rightarrow \langle \text{skip}, \langle s, h \rangle \rangle \\
\text{if } B & \rightarrow C_1,\langle s, h \rangle \rightarrow \langle C_1, \langle s, h \rangle \rangle \\
\text{while } B & \rightarrow C_2,\langle s, h \rangle \rightarrow \langle \text{skip},\langle \text{skip}, \langle s, h \rangle \rangle \rangle \\
\text{while } B & \rightarrow C_1,\langle s, h \rangle \rightarrow \langle C_1, \langle s, h \rangle \rangle \\
\text{while } B & \rightarrow C_2,\langle s, h \rangle \rightarrow \langle \text{skip}, \langle s, h \rangle \rangle \\
\text{while } B & \rightarrow C_1,\langle s, h \rangle \rightarrow \langle C_1, \langle s, h \rangle \rangle \\
\text{while } B & \rightarrow C_2,\langle s, h \rangle \rightarrow \langle \text{skip}, \langle s, h \rangle \rangle \\
\end{align*}
\]

Heap dereferencing

Dereferencing an allocated location stores the value at that location to the target program variable:

\[
E[X \leftarrow E_1,\langle s,h \rangle] \rightarrow \langle \text{skip}, \langle s[X \leftarrow N], h \rangle \rangle
\]

Dereferencing an unallocated location and dereferencing something that is not a location lead to a fault:

\[
\begin{align*}
E[E_1] & \rightarrow \ell \notin \text{dom}(h) \\
\exists \ell. E[E_1] & \rightarrow \ell
\end{align*}
\]

Heap assignment

Assigning to an allocated location updates the heap at that location with the assigned value:

\[
\begin{align*}
E[E_1] & \rightarrow \ell \in \text{dom}(h) \\
E[E_2] & \rightarrow N \rightarrow \langle E_1 \leftarrow E_2,\langle s, h \rangle \rangle \rightarrow \langle \text{skip}, \langle s, h[\ell \leftarrow N] \rangle \rangle
\end{align*}
\]

Assigning to an unallocated location or to something that is not a location leads to a fault:

\[
\begin{align*}
E[E_1] & \rightarrow \ell \notin \text{dom}(h) \\
\exists \ell. E[E_1] & \rightarrow \ell
\end{align*}
\]
Deallocate an allocated slot

\[
E[E](s) = \ell \quad \ell \in \text{dom}(h)
\]

\[
\langle \text{dispose}(E), (s, h) \rangle \rightarrow \langle \text{skip}, (s, h \setminus \{\ell, h(\ell)\}) \rangle
\]

Deallocating an unallocated location or something that is not a location leads to a fault:

\[
E[E](s) = \ell \quad \ell \notin \text{dom}(h)
\]

\[
\langle \text{dispose}(E), (s, h) \rangle \rightarrow \bot
\]

\[
\forall i \in \{0, \ldots, n\}, \ell + i \notin \text{dom}(h)
\]

\[
\ell \neq \text{null}
\]

\[
\langle X := \text{alloc}(E_0, \ldots, E_n), (s, h) \rangle \rightarrow \langle \text{skip}, (s[X \mapsto \ell], h[\ell \mapsto N_1, \ldots, \ell + n \mapsto N_n]) \rangle
\]

Because the heap has a finite domain, it is always possible to pick a suitable \( \ell \), so allocation never faults.

We will show that reasoning about pointers in Hoare logic is not practicable.

To do so, we will first show what makes compositional reasoning possible in standard Hoare logic (in the absence of pointers), and then show how it fails when we introduce pointers.
Approximating modified program variables

We can syntactically overapproximate the set of program variables that might be modified by a command $C$:

$$mod(\text{skip}) = \emptyset$$

$$mod(X := E) = \{X\}$$

$$mod(C_1; C_2) = mod(C_1) \cup mod(C_2)$$

$$mod(\text{if } B \text{ then } C_1 \text{ else } C_2) = mod(C_1) \cup mod(C_2)$$

$$mod(\text{while } B \text{ do } C) = mod(C)$$

$$mod([E_1] := E_2) = \emptyset$$

$$mod(X := [E]) = \{X\}$$

$$mod(X := \text{alloc}(E_0, \ldots, E_n)) = \{X\}$$

$$mod(\text{dispose}(E)) = \emptyset$$

For reference: free variables

The set of free variables of a term and of an assertion is given by

$$FV(-) : \text{Term} \rightarrow \mathcal{P}(\text{Var})$$

$$FV(\chi) \overset{\text{def}}{=} \{\chi\}$$

$$FV(f(t_1, \ldots, t_n)) \overset{\text{def}}{=} FV(t_1) \cup \ldots \cup FV(t_n)$$

and

$$FV(-) : \text{Assertion} \rightarrow \mathcal{P}(\text{Var})$$

$$FV(\top) = FV(\bot) \overset{\text{def}}{=} \emptyset$$

$$FV(P \land Q) = FV(P \lor Q) = FV(P \Rightarrow Q) \overset{\text{def}}{=} FV(P) \cup FV(Q)$$

$$FV(\forall v. P) = FV(\exists v. P) \overset{\text{def}}{=} FV(P) \setminus \{v\}$$

$$FV(t_1 = t_2) \overset{\text{def}}{=} FV(t_1) \cup FV(t_2)$$

$$FV(p(t_1, \ldots, t_n)) \overset{\text{def}}{=} FV(t_1) \cup \ldots FV(t_n)$$ respectively.

The rule of constancy

In standard Hoare logic (without the rules that we will introduce later, and thus without the new commands we have introduced), the rule of constancy expresses that assertions that do not refer to program variables modified by a command are automatically preserved during its execution:

$$\vdash \{P\} C \{Q\} \quad mod(C) \cap FV(R) = \emptyset$$

$$\vdash \{P \land R\} C \{Q \land R\}$$

This rule is admissible in standard Hoare logic.

Modularity and the rule of constancy

This rule is important for modularity, as it allows us to only mention the part of the state that we access.

Using the rule of constancy, we can separately verify two complicated commands:

$$\vdash \{P\} C_1 \{Q\} \quad \vdash \{R\} C_2 \{S\}$$

and then, as long as they use different program variables, we can compose them.

For example, if $mod(C_1) \cap FV(R) = \emptyset$ and $mod(C_2) \cap FV(Q) = \emptyset$, we can compose them sequentially:

$$\vdash \{P \land R\} C_1 \{Q \land R\} \quad \vdash \{R \land Q\} C_2 \{S \land Q\}$$

$$\vdash \{P \land R\} C_1 \{Q \land S\}$$
A bad rule for reasoning about pointers

Imagine we extended Hoare logic with a new assertion, \( t_1 \rightarrow t_2 \), for asserting that location \( t_1 \) currently contains the value \( t_2 \), and extended the proof system with the following (sound) rule:

\[
\vdash \{ \top \} [E_1] := E_2 \ (E_1 \rightarrow E_2)
\]

Then we would lose the rule of constancy, as using it, we would be able to derive

\[
\vdash \{ \top \} [37] := 42 \ (37 \rightarrow 42) \quad \text{mod}([37] := 42) \cap \text{FV}(Y \rightarrow 0) = \emptyset
\]

\[
\vdash \{ \top \land Y \rightarrow 0 \} [37] := 42 \ (37 \rightarrow 42 \land Y \rightarrow 0)
\]

even if \( Y = 37 \), in which case the postcondition would require 0 to be equal to 42.

There is a problem!

Reasoning about pointers

In the presence of pointers, we can have aliasing: syntactically distinct expressions can refer to the same location. Updates made through one expression can thus influence the state referenced by other expressions.

This complicates reasoning, as we explicitly have to track inequality of pointers to reason about updates:

\[
\vdash \{ E_1 \neq E_3 \land E_3 \leftrightarrow E_4 \} [E_1] := E_2 \ (E_1 \leftrightarrow E_2 \land E_3 \leftrightarrow E_4)
\]

We have to assume that any location is possibly modified unless stated otherwise in the precondition. This is not compositional at all, and quickly becomes unmanageable.

Separation logic

Separation logic is an extension of Hoare logic that enables modular reasoning about resources. It introduces new connectives to reason about the combination of disjoint resources.

We will use separation logic to reason about pointers in \( \text{WHILE}_p \). Our resources will be parts of the heap, and we will use the new connectives of separation logic to control aliasing.

Where a Hoare logic assertion refers to a (freely duplicable) property of the current state, a separation logic assertion asserts ownership of resources. Resources can be combined or compared (and exchanged), but need to be accounted for.
**History and terminology**

Separation logic was proposed by John Reynolds in 2000, and developed further by Peter O’Hearn and Hongseok Yang around 2001. It is still a very active area of research.

There are many variants of separation logic.

In WHILE, the heap in explicitly managed: the program is meant to dispose of heap locations itself. To be able to show that our programs do not leak memory, we are going to consider a so-called linear (or classical) separation logic. If we were not interested in reasoning about deallocation, for example because there is no garbage collector, we could use an affine (or intuitionistic) separation logic.

**The points-to assertion**

We introduce a new assertion, written $t_1 \mapsto t_2$, and read "$t_1$ points to $t_2$", to reason about individual heap cells.

The points-to assertion $t_1 \mapsto t_2$

- asserts that the current value that heap location $t_1$ maps to is $t_2$ (like $t_1 \mapsto t_2$), and
- asserts ownership of heap location $t_1$.

For example, $X \mapsto Y + 1$ asserts that the current value of heap location $X$ is $Y + 1$, and moreover asserts ownership of that heap location.

**The separating conjunction**

Separation logic extends Hoare logic with a new connective, the separating conjunction '$\ast$', to reason about disjoint resources.

The assertion $P \ast Q$ asserts that $P$ and $Q$ hold (somewhat like $P \land Q$); however, it also asserts that the resources (the parts of the heap) owned by $P$ and $Q$ are disjoint.

The separating conjunction has a neutral element, $\text{emp}$, which describes the empty resource (the empty heap):

\[ \text{emp} \ast P \iff P \iff P \ast \text{emp}. \]

**Examples of separation logic assertions**

1. $(X \mapsto t_1) \ast (Y \mapsto t_2)$

   This assertion is unsatisfiable in a state where $X$ and $Y$ refer to the same location, since $X \mapsto t_1$ and $Y \mapsto t_2$ would both assert ownership of the same location.

   A heap satisfying this assertion is of the following shape:

   $X \mapsto t_1 \quad t_2 \mapsto Y$

2. $(X \mapsto t) \ast (X \mapsto t)$

   This assertion is not satisfiable, as $X$ is not disjoint from itself.
Examples of separation logic assertions

3. $X \mapsto t_1 \land Y \mapsto t_2$

This asserts that the heap is described by $X \mapsto t_1$, and also by $Y \mapsto t_2$.
Therefore, $X$ and $Y$ alias each other, and $t_1 = t_2$

4. $(X \mapsto Y) * (Y \mapsto X)$

Here, $X \mapsto t$, ..., $t_n$ is shorthand for
$(X \mapsto t_0) * (X + 1 \mapsto t_1) * \cdots * (X + n \mapsto t_n)$

5. $(X \mapsto t_0, Y) * (Y \mapsto t_1, \text{null})$

X \[ \begin{array}{c} \text{null} \\ \vdots \\ \text{null} \end{array} \]

6. $\exists x, y. \ (\text{HEAD} \mapsto 12, x) * (x \mapsto 99, y) * (y \mapsto 37, \text{null})$

This describes our singly linked list from earlier:

\[ \text{HEAD} \rightarrow 12 \rightarrow 99 \rightarrow 37 \rightarrow \text{null} \]

Examples of separation logic assertions

Semantics of separation logic assertions
Semantics of separation logic assertions

The semantics of a separation logic assertion \( P, [P] \), is the set of states (that is, pairs of a stack and a heap) that satisfy \( P \).

It is simpler to define it indirectly, through the semantics of \( P \) given a stack \( s \), written \([P](s)\), which is the set of heaps that, together with stack \( s \), satisfy \( P \).

Recall that we want to capture the notion of ownership: if \( h \in [P](s) \), then \( P \) should assert ownership of any locations in \( \text{dom}(h) \).

The heaps \( h \in [P](s) \) are thus referred to as partial heaps, since they only contain the locations owned by \( P \).

Semantics of separation logic assertions: points-to

The points-to assertion \( t_1 \mapsto t_2 \) asserts ownership of the location referenced by \( t_1 \), and that this location currently contains \( t_2 \):

\[
[t_1 \mapsto t_2](s) \overset{def}{=} \begin{cases} h \in \text{Heap} \\
\exists \ell, N. \begin{cases} t_1(s) = \ell \land \\
\ell \neq \text{null} \land \\
\text{dom}(h) = \{\ell\} \land \\
h(\ell) = N \end{cases} \end{cases}
\]

\( t_1 \mapsto t_2 \) only asserts ownership of location \( \ell \), so to capture ownership, requires \( \text{dom}(h) = \{\ell\} \).

Semantics of separation logic assertions: \(*\)

Separating conjunction, \( P * Q \), asserts that the heap can be split into two disjoint parts such that one satisfies \( P \), and the other \( Q \):

\[
[P * Q](s) \overset{def}{=} \begin{cases} h \in \text{Heap} \\
\exists h_1, h_2. \begin{cases} h_1 \in [P](s) \land \\
h_2 \in [Q](s) \land \\
h = h_1 \uplus h_2 \end{cases} \end{cases}
\]

where \( h = h_1 \uplus h_2 \) is equal to \( h = h_1 \cup h_2 \), but only holds when \( \text{dom}(h_1) \cap \text{dom}(h_2) = \emptyset \).
Semantics of separation logic assertions: \(emp\)

The empty heap assertion only holds for the empty heap:

\[
\begin{align*}
\emp(s) & \triangleq \{ h \in \text{Heap} \mid \text{dom}(h) = \emptyset \}
\end{align*}
\]

\(emp\) does not assert ownership of any location, so to capture ownership, \(\text{dom}(h) = \emptyset\).

Summary: separation logic assertions

Separation logic assertions not only describe properties of the current state (as Hoare logic assertions did), but also assert ownership of parts of the current heap.

Separation logic controls aliasing of pointers by enforcing that assertions own disjoint parts of the heap.

Semantics of separation logic triples

Separation logic not only extends the assertion language, but strengthens the semantics of correctness triples in two ways:

- they ensure that commands do not fail;
- they ensure that the ownership discipline associated with assertions is respected.
Ownership and separation logic triples

Separation logic triples ensure that the ownership discipline is respected by requiring that the precondition asserts ownership of any heap cells that the command might use.

For instance, we want the following triple, which asserts ownership of location 37, stores the value 42 at this location, and asserts that after that location 37 contains value 42, to be valid:

\[ \vdash \{37 \mapsto \rightarrow 1\} [37] := 42 \{37 \mapsto \rightarrow 42\} \]

However, we do not want the following triple to be valid, because it updates a location that it is not the owner of:

\[ \nvdash \{100 \mapsto \rightarrow 1\} [37] := 42 \{100 \mapsto \rightarrow 1\} \]

even though the precondition ensures that the postcondition is true!

Framing

How can we make this principle that triples must assert ownership of the heap cells they modify precise?

The idea is to require that all triples must preserve any assertion that asserts ownership of a part of the heap disjoint from the part of the heap that their precondition asserts ownership of.

This is exactly what the separating conjunction, \(*\), allows us to express.

The frame rule

This intent that all triples preserve any assertion \(R\) disjoint from the precondition, called the frame, is captured by the frame rule:

\[
\vdash \{P\} C \{Q\} \quad \text{mod}(C) \cap FV(R) = \emptyset
\]

\[
\vdash \{P * R\} C \{Q * R\}
\]

The frame rule is similar to the rule of constancy, but uses the separating conjunction to express separation.

We still need to be careful about program variables (in the stack), so we need \(\text{mod}(C) \cap FV(R) = \emptyset\).

Examples of framing

How does preserving all frames force triples to assert ownership of heap cells they modify?

Imagine that the following triple did hold and preserved all frames:

\[ \{100 \mapsto \rightarrow 1\} [37] := 42 \{100 \mapsto \rightarrow 1\} \]

In particular, it would preserve the frame \(37 \mapsto \rightarrow 1\):

\[ \{100 \mapsto \rightarrow 1 \star 37 \mapsto \rightarrow 1\} [37] := 42 \{100 \mapsto \rightarrow 1 \star 37 \mapsto \rightarrow 1\} \]

This triple definitely does not hold, since location 37 contains 42 in the terminal state.
Examples of framing

This problem does not arise for triples that assert ownership of the heap cells they modify, since triples only have to preserve frames disjoint from the precondition.

For instance, consider this triple which asserts ownership of location 37:

\[
\{37 \mapsto 1\} \; [37] := 42 \; \{37 \mapsto 42\}
\]

If we frame on \(37 \mapsto 1\), then we get the following triple, which holds vacuously since no initial states satisfies \(37 \mapsto 42\) \(\neq\) \(37 \mapsto 1\):

\[
\{37 \mapsto 1 \neq 37 \mapsto 1\} \; [37] := 42 \; \{37 \mapsto 42 \neq 37 \mapsto 1\}
\]

Informal semantics of separation logic triples

The meaning of \(\{P\} C \{Q\}\) in separation logic is thus

- \(C\) does not fault when executed in an initial state satisfying \(P\), and
- if \(h_1\) satisfies \(P\), and if when executed from an initial state with an initial heap \(h_1 \cup h_F\), \(C\) terminates, then the terminal heap has the form \(h'_1 \cup h_F\), where \(h'_1\) satisfies \(Q\).

This bakes in the requirement that triples must satisfy framing, by requiring that they preserve all disjoint heaps \(h_F\).

Formal semantics of separation logic triples

Written formally, the semantics is:

\[
\models \{P\} C \{Q\} \overset{\text{def}}{=} \\
(\forall s, h. h \in [P](s) \Rightarrow \neg(((C, \langle s, h \rangle) \rightarrow^*)))) \land \\
(\forall s, h_1, h_F, s', h'. \text{dom}(h_1) \cap \text{dom}(h_F) = \emptyset \land \\
h_1 \in [P](s) \land (C, \langle s, h_1 \cup h_F \rangle) \rightarrow^* \langle \text{skip}, \langle s', h' \rangle \rangle \\
\Rightarrow \exists h'_1, h' = h'_1 \cup h_F \land h'_1 \in [Q](s'))
\]

We then have the semantic version of the frame rule baked in:

If \(\models \{P\} C \{Q\}\) and \(\text{mod}(C) \cap \text{FV}(R) = \emptyset\), then

\(\models \{P \ast R\} C \{Q \ast R\}\).

Summary

Separation logic is an extension of Hoare logic that enables modular reasoning about resources. It extends Hoare logic with new assertions, and refines the semantics of assertions to reason about ownership and separation.

We leverage this to control aliasing, which enables practical reasoning about pointers and mutable data structures.

In the next lecture, we will look at a proof system for separation logic, and apply separation logic to examples.

Papers of historical interest:

Recap

Last time, we introduced separation logic, a variant of Hoare logic that makes reasoning about pointers tractable.

Separation logic is based on the notions of separation and ownership.

A separation logic partial correctness triple ensures that the execution of the command (1) does not fault, and (2) only changes the part of the heap that the precondition asserts ownership of.

In this lecture, we will look at a proof system for separation logic, and put separation logic into practice.

A proof system for separation logic

Separation logic inherits all the partial correctness rules from Hoare logic from the first lecture, and extends them with

- structural rules, including the frame rule;
- rules for each new heap-manipulating command.

Some of the rules that were admissible for plain Hoare logic, for example the rule of constancy, are no longer sound for separation logic.

We now want the rule of consequence to be able manipulate our extended assertion language, with our new assertions $P \ast Q$, $t_1 \mapsto t_2$, and $emp$, and not just first-order logic anymore.
The frame rule

The frame rule is the core of separation logic. It expresses that separation logic triples always preserve any assertion disjoint from the precondition:

$$\vdash \{P\} C \{Q\} \quad \text{mod}(C) \cap \text{FV}(R) = \emptyset$$

$$\vdash \{P \ast R\} C \{Q \ast R\}$$

The second hypothesis ensures that the frame $R$ does not refer to any program variables modified by the command $C$.

This builds in modularity and compositionality.

The heap assignment rule

Separation logic triples must assert ownership of any heap cells modified by the command. The heap assignment rule thus asserts ownership of the heap location being assigned:

$$\vdash \{E_1 \mapsto t\} [E_1] := E_2 \{E_1 \mapsto E_2\}$$

If expressions were allowed to fault, we would need a more complex rule.

The heap dereference rule

Separation logic triples must ensure the command does not fault. The heap dereference rule thus asserts ownership of the given heap location to ensure the location is allocated in the heap:

$$\vdash \{E \mapsto u \land X = x\} X := [E] \{E[x/X] \mapsto u \land X = u\}$$

Here, $u$ and $x$ are auxiliary variables, and $x$ is used to refer to the initial value of program variable $X$ in the postcondition.

Other structural rules

Given the rules that we are going to consider for the heap-manipulating commands, we are going to need to include structural rules like the following:

$$\vdash \{P\} C \{Q\}$$

$$\vdash \exists x. P \quad C \quad \exists x. Q$$

Rules like these were admissible in Hoare logic.
Allocation and deallocation

The allocation rule introduces a new points-to assertion for each newly allocated location:

\[
\vdash \{ \text{X} \mapsto \text{x} \} \text{X} := \text{alloc}(E_0, \ldots, E_n) \{ X \mapsto E_0[x/X], \ldots, E_n[x/X] \}
\]

The deallocation rule destroys the points-to assertion for the location to not be available anymore:

\[
\vdash \{ E \mapsto t \} \text{dispose}(E) \{ \text{emp} \}
\]

Swap example

To illustrate these rules, consider the following code snippet:

\[
C_{\text{swap}} \equiv \text{A} := [\text{X}]; \; \text{B} := [\text{Y}]; [\text{X}] := \text{B}; [\text{Y}] := \text{A};
\]

We want to show that it swaps the values in the locations referenced by \text{X} and \text{Y}, when \text{X} and \text{Y} do not alias:

\[
\{ X \mapsto n_1 \ast Y \mapsto n_2 \} \text{ C}_{\text{swap}} \{ X \mapsto n_2 \ast Y \mapsto n_1 \}
\]

Proof outline for swap

\[
\{ X \mapsto n_1 \ast Y \mapsto n_2 \}
\]

\[
\text{A} := [\text{X}];
\]

\[
\{ (X \mapsto n_1 \ast Y \mapsto n_2) \land A = n_1 \}
\]

\[
\text{B} := [\text{Y}];
\]

\[
\{ (X \mapsto n_1 \ast Y \mapsto n_2) \land A = n_1 \land B = n_2 \}
\]

\[
[\text{X}] := \text{B};
\]

\[
\{ (X \mapsto B \ast Y \mapsto n_2) \land A = n_1 \land B = n_2 \}
\]

\[
[\text{Y}] := \text{A};
\]

\[
\{ (X \mapsto B \ast Y \mapsto A) \land A = n_1 \land B = n_2 \}
\]

\[
\{ X \mapsto n_2 \ast Y \mapsto n_1 \}
\]

Justifying these individual steps is now considerably more involved than in Hoare logic.
Detailed proof outline for the first triple of swap

\{ X \mapsto n_1 * Y \mapsto n_2 \}
\{ \exists a. ((X \mapsto n_1 * Y \mapsto n_2) \land A = a) \}
\{ (X \mapsto n_1 * Y \mapsto n_2) \land A = a \}
\{ X \mapsto n_1 \land A = a \}
A := [X]
\{ X[a/A] \mapsto n_1 \land A = n_1 \}
\{ X \mapsto m_1 \land A = n_1 \}
\{ ((X \mapsto n_1 \land A = n_1) \ast Y \mapsto n_2) \land A = n_1 \}
\{ \exists a. ((X \mapsto n_1 \ast Y \mapsto n_2) \land A = n_1) \}
\{ (X \mapsto n_1 \ast Y \mapsto n_2) \land A = n_1 \}

Proof of the first triple of swap (continued)

We relied on many properties of our assertion logic.

For example, to justify the first application of consequence, we need to show that

\[ \vdash P \Rightarrow \exists a. (P \land A = a) \]

and to justify the last application of consequence, we need to show that:

\[ \vdash ((X \mapsto n_1 \land A = n_1) \ast Y \mapsto n_2) \Rightarrow ((X \mapsto n_1 \ast Y \mapsto n_2) \land A = n_1) \]

For reference: proof of the first triple of swap

Put another way:
To prove this first triple, we use the heap dereference rule to derive:

\{ X \mapsto n_1 \land A = a \} \quad A := [X] \{ X[a/A] \mapsto n_1 \land A = n_1 \}

Then we existentially quantify the auxiliary variable a:

\{ \exists a. X \mapsto n_1 \land A = a \} \quad A := [X] \{ \exists a. X[a/A] \mapsto n_1 \land A = n_1 \}

Applying the rule of consequence, we obtain:

\{ X \mapsto m_1 \} \quad A := [X] \{ X \mapsto m_1 \land A = n_1 \}

Since A := [X] does not modify Y, we can frame on Y \mapsto n_2:

\{ X \mapsto n_1 \ast Y \mapsto n_2 \} \quad A := [X] \{ (X \mapsto n_1 \land A = n_1) \ast Y \mapsto n_2 \}

Lastly, by the rule of consequence, we obtain:

\{ X \mapsto n_1 \ast Y \mapsto n_2 \} \quad A := [X] \{ (X \mapsto n_1 \ast Y \mapsto n_2) \land A = n_1 \}

Properties of separation logic assertions
Syntax of assertions in separation logic

We now have an extended language of assertions, with a new connective, the separating conjunction $\ast$:

\[
P, Q ::= \bot | \top | P \land Q | P \lor Q | P \Rightarrow Q | P \ast Q | \text{emp} | \forall v. P | \exists v. P | t_1 = t_2 | p(t_1, \ldots, t_n) \quad n \geq 0
\]

$\Rightarrow$ is a predicate symbol of arity 2.

This is not just usual first-order logic anymore: this is an instance of the classical first-order logic of bunched implication (which is related to linear logic).

We will also require inductive predicates later.

We will take an informal look at what kind of properties hold and do not hold in this logic. Using the semantics, we can prove the properties we need as we go.

Properties of separating conjunction

Separating conjunction is a commutative and associative operator with $\text{emp}$ as a neutral element (like $\land$ was with $\top$):

\[
\vdash P \ast Q \Leftrightarrow Q \ast P
\]

\[
\vdash (P \ast Q) \ast R \Leftrightarrow P \ast (Q \ast R)
\]

\[
\vdash P \ast \text{emp} \Leftrightarrow P
\]

Separating conjunction is monotone with respect to implication:

\[
\vdash P_1 \Rightarrow Q_1 \quad \vdash P_2 \Rightarrow Q_2
\]

\[
\vdash P_1 \ast P_2 \Rightarrow Q_1 \ast Q_2
\]

Separating conjunction distributes over disjunction:

\[
\vdash (P \lor Q) \ast R \Leftrightarrow (P \ast R) \lor (Q \ast R)
\]

Properties of pure assertions

An assertion is pure when it does not talk about the heap. Syntactically, this means it does not contain $\text{emp}$ or $\Rightarrow$.

Separating conjunction and conjunction become more similar when they involve pure assertions:

\[
\vdash P \land Q \Rightarrow P \ast Q \quad \text{when } P \text{ or } Q \text{ is pure}
\]

\[
\vdash P \ast Q \Rightarrow P \land Q \quad \text{when } P \text{ and } Q \text{ are pure}
\]

\[
\vdash (P \land Q) \ast R \Leftrightarrow P \land (Q \ast R) \quad \text{when } P \text{ is pure}
\]
Axioms for the points-to assertion

null cannot point to anything:

\[ \vdash \forall t_1, t_2. t_1 \rightarrow t_2 \Rightarrow (t_1 \rightarrow t_2 \neq \text{null}) \]

locations combined by * are disjoint:

\[ \vdash \forall t_1, t_2, t_3, t_4. (t_1 \rightarrow t_2 \ast t_3 \rightarrow t_4) \Rightarrow (t_1 \rightarrow t_2 \ast t_3 \rightarrow t_4 * t_1 \neq t_3) \]

Assertions in separation logic are not freely duplicable in general: we do not have \( \vdash P \Rightarrow P \ast P \) for all \( P \). Therefore, in general, we need to repeat the assertions on the right-hand side of the implication to not “lose” them.

Verifying abstract data types

Separation logic is very well-suited for specifying and reasoning about data structures typically found in standard libraries such as lists, queues, stacks, etc.

To illustrate this, we will specify and verify a library for working with lists, implemented using null-terminated singly-linked lists, using separation logic.

A list library implemented using singly-linked lists

First, we need to define a memory representation for our lists.

We will use null-terminated singly-linked list, starting from some designated HEAD program variable that refers to the first element of the linked list. (We have to make do with this in WHILE\(_p\).)

For instance, we will represent the mathematical list \([12, 99, 37]\) as we did in the previous lecture:

\[
\text{HEAD} \quad 12 \quad 99 \quad 37
\]
Representation predicates

To formalise the memory representation, separation logic uses representation predicates that relate an abstract description of the state of the data structure with its concrete memory representations.

For our example, we want a predicate \(\text{list}(t, \alpha)\) that relates a mathematical list, \(\alpha\), with its memory representation starting at location \(t\) (here, \(\alpha, \beta, \ldots\) are just terms, but we write them differently to clarify the fact that they refer to mathematical lists).

To define such a predicate formally, we need to extend the assertion logic to reason about inductively defined predicates. We probably also want to extend it to reason about mathematical lists directly rather than through encodings. We will elide these details.

We are going to define the \(\text{list}(t, \alpha)\) predicate by induction on the list \(\alpha\):

- The empty list \(\[]\) is represented as a null pointer:
  \[
  \text{list}(t, \[]) \overset{df}{=} t = \text{null}
  \]

- The list \(h :: \alpha\) (again, \(h\) is just a term) is represented by a pointer to two consecutive heap cells that contain the head \(h\) of the list and the location of the representation of the tail \(\alpha\) of the list, respectively:
  \[
  \text{list}(t, h :: \alpha) \overset{df}{=} \exists y. (t \mapsto h) \ast ((t + 1) \mapsto y) \ast \text{list}(y, \alpha)
  \]
  (recall that \(t \mapsto h \Rightarrow ((t \mapsto h) \ast t \neq \text{null})\))

The representation predicate allows us to specify the behaviour of the list operations by their effect on the abstract state of the list.

For example, assuming that we represent the mathematical list \(\alpha\) at location \(\text{HEAD}\), we can specify a push operation \(C_{\text{push}}\) that pushes the value of program variable \(X\) onto the list in terms of its behaviour on the abstract state of the list as follows:

\[
\{\text{list}(\text{HEAD}, \alpha) \wedge X = x\} C_{\text{push}} \{\text{list}(\text{HEAD}, x :: \alpha)\}
\]

The \(\text{emp}\) in the postcondition of \(C_{\text{delete}}\) ensures that the locations of the precondition have been deallocated.
Implementation of push

The push operation stores the HEAD pointer into a temporary variable Y before allocating two consecutive locations for the new list element, storing the start-of-block location to HEAD:

\[ C_{\text{push}} \equiv Y := \text{HEAD}; \text{HEAD} := \text{alloc}(X, Y) \]

We wish to prove that \( C_{\text{push}} \) satisfies its intended specification:

\[ \{ \text{list}(\text{HEAD}, \alpha) \land X = x \} \quad C_{\text{push}} \quad \{ \text{list}(\text{HEAD}, x :: \alpha) \} \]

(We could use \( \text{HEAD} := \text{alloc}(X, \text{HEAD}) \) instead.)

Proof outline for push

Here is a proof outline for the push operation:

\[ \{ \text{list}(\text{HEAD}, \alpha) \land X = x \} \]
\[ Y := \text{HEAD} \]
\[ \{ \text{list}(Y, \alpha) \land X = x \} \]
\[ \text{HEAD} := \text{alloc}(X, Y) \]
\[ \{ (\text{list}(Y, \alpha) \ast \text{HEAD} \rightarrow X, Y) \land X = x \} \]
\[ \{ \text{list}(\text{HEAD}, X :: \alpha) \land X = x \} \]
\[ \{ \text{list}(\text{HEAD}, x :: \alpha) \} \]

For the alloc step, we frame off \( \text{list}(Y, \alpha) \land X = x \).

For reference: detailed proof outline for the allocation

\[ \{ \text{list}(Y, \alpha) \land X = x \} \]
\[ \exists z. \{ \text{list}(Y, \alpha) \land X = x \} \land \text{HEAD} = z \]
\[ \{ \{ \text{list}(Y, \alpha) \land X = x \} \land \text{HEAD} = z \} \]
\[ \{ \{ \text{list}(Y, \alpha) \land X = x \} \ast \text{HEAD} = z \} \]
\[ \{ \text{HEAD} = z \} \]
\[ \text{HEAD} := \text{alloc}(X, Y) \]
\[ \{ \text{HEAD} \rightarrow X[z/\text{HEAD}], Y[z/\text{HEAD}] \} \]
\[ \{ \text{HEAD} \rightarrow X, Y \} \]
\[ \{ \{ \text{list}(Y, \alpha) \land X = x \} \ast \text{HEAD} \rightarrow X, Y \} \]
\[ \{ \{ \text{list}(Y, \alpha) \ast \text{HEAD} \rightarrow X, Y \land X = x \} \}
\[ \exists z. \{ \text{list}(Y, \alpha) \ast \text{HEAD} \rightarrow X, Y \land X = x \} \]
\[ \{ \{ \text{list}(Y, \alpha) \ast \text{HEAD} \rightarrow X, Y \land X = x \} \}

Implementation of delete

The delete operation iterates down over the list, deallocating nodes until it reaches the end of the list.

\[ C_{\text{delete}} \equiv X := \text{HEAD}; \]
\[ \text{while } X \neq \text{null do} \]
\[ (Y := [X + 1], \text{dispose}(X); \text{dispose}(X + 1); X := Y) \]

We wish to prove that \( C_{\text{delete}} \) satisfies its intended specification:

\[ \{ \text{list}(\text{HEAD}, \alpha) \} \quad C_{\text{delete}} \quad \{ \text{emp} \} \]

For that, we need a suitable loop invariant.
To execute safely, \( X \) effectively needs to point to a list (which is \( \alpha \) only at the start).
Proof outline for delete

We can pick the invariant that we own the rest of the list:

\( \{ \text{list}(\text{HEAD}, \alpha) \} \)

\( X := \text{HEAD}; \)

\( \{ \text{list}(X, \alpha) \} \)

\( \{ \exists \beta. \text{list}(X, \beta) \} \)

while \( X \neq \text{null} \) do

\( \{ \exists \beta. \text{list}(X, \beta) \land X \neq \text{null} \} \)

\( (Y := [X + 1]; \text{dispose}(X); \text{dispose}(X + 1); X := Y) \)

\( \{ \exists \beta. \text{list}(X, \beta) \} \)

\( \{ \exists \beta. \text{list}(X, \beta) \land \neg(X \neq \text{null}) \} \)

\( \{ \text{emp} \} \)

We need to complete the proof outline for the body of the loop.

Linear separation logic and deallocation

Linear separation logic forces us to deallocate.

If we did not have the two deallocations in the body of the loop, we would have to do something with

\( (X \mapsto h) * (X + 1 \mapsto Y) \)

We can weaken that assertion to \( \top \), but not fully eliminate it.

We could weaken our loop invariant to \( \exists \beta. \text{list}(X, \beta) * \top \): the \( \top \) would indicate the memory leak.

Proof outline for the loop body of delete

To verify the loop body, we need a lemma to unfold the list representation predicate in the non-null case:

\( \{ \exists \beta. \text{list}(X, \beta) \land X \neq \text{null} \} \)

\( \{ \exists h, y, \gamma. X \mapsto \rightarrow h, y * \text{list}(y, \gamma) \} \)

\( Y := [X + 1]; \)

\( \{ \exists h, \gamma. X \mapsto \rightarrow h, Y * \text{list}(Y, \gamma) \} \)

\( \text{dispose}(X); \text{dispose}(X + 1); \)

\( \{ \exists \gamma. \text{list}(Y, \gamma) \} \)

\( X := Y \)

\( \{ \exists \gamma. \text{list}(X, \gamma) \} \)

\( \{ \exists \beta. \text{list}(X, \beta) \} \)

Implementation of max

The max operation iterates over a non-empty list, computing its maximum element:

\( C_{\text{max}} := \)

\( X := [\text{HEAD} + 1]; M := [\text{HEAD}]; \)

while \( X \neq \text{null} \) do

\( (E := [X]; \text{if } E > M \text{ then } M := E \text{ else skip}; X := [X + 1]) \)

We wish to prove that \( C_{\text{max}} \) satisfies its intended specification:

\( \{ \text{list}(\text{HEAD}, h :: \alpha) \} C_{\text{max}} \{ \text{list}(\text{HEAD}, h :: \alpha) * M = \text{max}(h :: \alpha) \} \)

For that, we need a suitable loop invariant. However, the lists represented starting at \( \text{HEAD} \) and \( X \) are not disjoint.
Representation predicate for partial lists

To talk about partial lists, we can define a representation predicate for partial lists, \(\text{plist}(t_1, \alpha, t_2)\), inductively:

\[
\text{plist}(t_1, [], t_2) \overset{\text{def}}{=} (t_1 = t_2)
\]

\[
\text{plist}(t_1, h :: \alpha, t_2) \overset{\text{def}}{=} (\exists y. t_1 \rightarrow h, y \circ \text{plist}(y, \alpha, t_2))
\]

such that \(\text{list}(t, \alpha \circ \beta) \Leftrightarrow \exists y. \text{plist}(t, \alpha, y) \circ \text{list}(y, \beta)\)

In particular, we can split lists in the middle:

\[
(\exists t_2. \text{plist}(t_1, \alpha, t_2) \circ \text{list}(t_2, \beta)) \Leftrightarrow \text{list}(t_1, \alpha \circ \beta)
\]

Implementation of \textit{merge} (of merge sort)

{\text{list}(X, \alpha) \circ \text{list}(Y, \beta) \circ \text{sorted}(\alpha) \circ \text{sorted}(\beta)}
\[Z := \text{alloc}(0, \text{null}); P := Z;\]
\[
\text{while } X \neq \text{null} \text{ and } Y \neq \text{null} \text{ do}
\]
\[
\begin{pmatrix}
U := [X]; V := [Y]; \\
\text{if } U \leq V \text{ then } ([P + 1] := X; X := [X + 1]) \\
\text{else } ([P + 1] := Y; Y := [Y + 1]); \\
P := [P + 1]
\end{pmatrix}
\]
\[
\text{if } X = \text{null} \text{ then } ([P + 1] := Y; Y := \text{null}) \\
\text{else } ([P + 1] := X; X := \text{null}); \\
P := [Z + 1]; \text{dispose}(Z); \text{dispose}(Z + 1); Z := P
\]
{\text{list}(Z, \gamma) \circ \text{sorted}(\gamma) \circ \text{Permutation}(\gamma, \alpha \circ \beta)}

We need to find a suitable invariant

Proof outline for \textit{max}

We can use \textit{plist} to express our invariant:

{\text{list}(\text{HEAD}, h :: \alpha)}
\[X := [\text{HEAD} + 1]; M := [\text{HEAD}];\]

{\text{plist}(\text{HEAD}, [h], X) \circ \text{list}(X, \alpha) \circ M = \text{max}([h])}
\{\exists \gamma, h :: \alpha = \beta \circ \gamma \circ \text{plist}(\text{HEAD}, \beta, X) \circ \text{list}(X, \gamma) \circ M = \text{max}(\beta)\}
\[
\text{while } X \neq \text{null} \text{ do}
\]
\[
(E := [X]; \text{if } E > M \text{ then } M := E \text{ else skip}; X := [X + 1])
\]
{\text{list}(\text{HEAD}, h :: \alpha) \circ M = \text{max}(h :: \alpha)}

Specification of \textit{merge}

We did not need to change our representation predicate: we only need to state that the mathematical list that is represented is sorted:

\[
\text{sorted}([]) \overset{\text{def}}{=} \top
\]

\[
\text{sorted}([x]) \overset{\text{def}}{=} \top
\]

\[
\text{sorted}(x :: y :: \alpha) \overset{\text{def}}{=} x \leq y \wedge \text{sorted}(y :: \alpha)
\]

and that a list is a permutation of another:

\[
\text{Permutation}(\alpha, \beta) \overset{\text{def}}{=}
\]
\[
(\alpha = \beta = []) \lor
(\exists a, a', \beta'. \alpha = [a] :: \alpha' \wedge \beta = [a] :: \beta' \wedge \text{Permutation}(\alpha', \beta')) \lor
(\exists a, b, \gamma. \alpha = [a] :: [b] :: \gamma \wedge \beta = [b] :: [\gamma]) \lor
(\exists \gamma. \text{Permutation}(\alpha, \gamma) \wedge \text{Permutation}(\gamma, \beta))
\]
Invariant of merge

We can now express our invariant:

\[ \exists \alpha_1, \alpha_2, \beta_1, \beta_2, \gamma, \gamma_1, a. \]
\[ \alpha = \alpha_1 + + \alpha_2 \ast \beta = \beta_1 + + \beta_2 \ast \]
\[ \text{sorted}(\alpha) \ast \text{sorted}(\beta) \ast \]
\[ \text{list}(X, \alpha_2) \ast \text{list}(Y, \beta_2) \ast \]
\[ \text{sorted}(\gamma) \ast \gamma_1 + + [a] = 0 :: \gamma \ast \]
\[ \text{plist}(Z, \gamma_1, P) \ast \text{list}(P, [a]) \ast \]
\[ \text{Permutation}(\gamma, \alpha_1 + + \beta_1) \]

It is a rather readable — albeit detailed — description of why the program is correct.

Summary

We can specify abstract data types using representation predicates which relate an abstract model of the state of the data structure with a concrete memory representation.

We only need to know what the representation predicate is when we add a new operation to our library, not when we use it. This gives us abstraction and modularity.

Justification of individual steps has to be made quite carefully given the unfamiliar interaction of connectives in separation logic, but proof outlines remain very readable.

Recap

Last time, we looked at how separation logic enables modular reasoning.

In this lecture, we will consider extending Hoare logic in other directions:

- We will look at extending partial correctness triples to enforce termination, and at adapting the Hoare logic rules for partial correctness to total correctness.
- We will look at how to handle (a crude form of) procedures.
- We will look at how to reason about simple forms of concurrency.
Total correctness

So far, we have concerned ourselves only with partial correctness, and not with what happens when the program diverges.

However, in many contexts where we care about correctness enough to use Hoare logic for verification, we also care about termination.

Total correctness triples

There is no standard notation for total correctness triples; we will use \([P] C [Q]\).

The total correctness triple \([P] C [Q]\) holds if and only if:

- assuming \(C\) is executed in an initial state satisfying \(P\),
- then the execution terminates,
- and the terminal state satisfies \(Q\).

Semantics of total correctness triples

A total correctness triple asserts that when the given command is executed from an initial state that satisfies the precondition, then any execution must terminate, and that any terminal state satisfies the postcondition:

\[
\models [P] C [Q] \overset{\text{def}}{=} \\
\forall s. s \in [P] \Rightarrow \left( \neg((C, s) \rightarrow^\omega) \land \forall s'. (C, s) \rightarrow (\text{skip}, s') \land s' \in [Q] \right)
\]
Semantics of total correctness triples

Since WHILE is safe and deterministic, this is equivalent to

\[ \forall s. s \in \mathbb{P} \Rightarrow \exists s'. \langle C, s \rangle \rightarrow \langle \text{skip}, s' \rangle \land s' \in \mathbb{Q} \]

Assume \( s \in \mathbb{P} \) and \( \langle C, s \rangle \rightarrow^* \langle \text{skip}, s' \rangle \).

Since WHILE is safe and deterministic, \( \neg(\langle C, s \rangle \rightarrow^\omega) \). Moreover, since WHILE is deterministic, for all \( s'' \) such that \( \langle C, s \rangle \rightarrow^* \langle \text{skip}, s'' \rangle \), \( s'' = s' \), so \( s'' \in \mathbb{Q} \).

Examples of total correctness triples

- The following total correctness triple is valid:
  \[ \models [X \geq 0] \text{while } X \geq 0 \text{ do } X := X - 1 [X = 0] \]
  the loop terminates when executed from an initial state where \( X \) is non-negative.

- The following total correctness triple is not valid:
  \[ \nmodels [\top] \text{while } X \geq 0 \text{ do } X := X - 1 [X = 0] \]
  the loop only terminates when executed from an initial state where \( X \) is non-negative, but not when executed from an initial state where \( X \) is negative.

Corner cases of total correctness triples

\([P] C [\top]\)

- this says that \( C \) always terminates when executed from an initial state satisfying \( P \).

\([\top] C [Q]\)

- this says that \( C \) always terminates, and ends up in a state where \( Q \) holds.

Rules for total correctness

while commands are the commands that introduce non-termination.

Except for the loop rule, all the rules of Hoare logic (from the first lecture) are sound for total correctness as well as partial correctness.

\[ \begin{align*}
\models [P] \text{skip} [P] & \quad \models [P[E/X]] X := E [P] \\
\models [P] C_1 [Q] \land [Q] C_2 [R] & \quad \models [P \land B] C_1 [Q] \land [P \land \neg B] C_2 [Q] \\
\models [P] C_1 ; C_2 [R] & \quad \models [P] \text{if } B \text{ then } C_1 \text{ else } C_2 [Q] \\
\models P_1 \Rightarrow P_2 & \quad \models [P_2] C [Q_2] \land Q_2 \Rightarrow Q_1 \\
\models [P_1] C [Q_1] &
\end{align*} \]
Unsoundness of the partial correctness loop rule for total correctness

The loop rule that we have for partial correctness is not sound for total correctness:

\[
\vdash (T \land T) \Rightarrow T \quad \vdash \{T\} \text{skip} \{T\} \quad \vdash \top \Rightarrow T
\]

\[
\vdash \{T\} \text{while} T \text{do} \{T \land \neg T\}
\]

\[
\vdash \top \Rightarrow \bot
\]

If the loop rule were sound for total correctness, then this would show that \textit{while T do skip} always terminates in a state satisfying \(\bot\).

Loop variants

We need an alternative total correctness loop rule that ensures that the loop always terminates.

The idea is to show that some non-negative integer quantity decreases on each iteration of the loop.

If this is the case, then the loop terminates, as there would otherwise be an infinite decreasing sequence of natural numbers.

This decreasing quantity is called a variant.

Loop rule for total correctness

In the rule below, the variant is \(t\), and the fact that it decreases is specified with an auxiliary variable \(n\):

\[
\vdash [P \land B \land (t = n)] C [P \land (t < n)] \quad \vdash P \land B \Rightarrow t \geq 0
\]

\[
\vdash [P] \text{while} B \text{do} C [P \land \neg B]
\]

The second hypothesis ensures that the variant is non-negative.

The variant \(t\) does not have to occur in \(C\).

Backwards reasoning total correctness loop rule

Using the rule of consequence, we can derive the following backwards reasoning total correctness loop rule:

\[
\vdash P \Rightarrow I \quad \vdash I \land \neg B \Rightarrow Q
\]

\[
\vdash I \land B \Rightarrow t \geq 0 \quad \vdash [I \land B \land (t = n)] C [I \land (t < n)]
\]

\[
\vdash [P] \text{while} B \text{do} C [Q]
\]
Consider the factorial computation we looked at before:

\[ X = x \land X \geq 0 \land Y = 1 \]

while \( X \neq 0 \) do (\( Y := Y \times X; X := X - 1 \))

\[ Y = x! \]

By assumption, \( X \) is non-negative and decreases in each iteration of the loop.

To verify that this factorial implementation terminates, we can thus take the variant \( t \) to be \( X \).

Take \( I \) to be \( Y \times X != x! \land X \geq 0 \), and \( t \) to be \( X \).

Then we have to show that

- \( X = x \land X \geq 0 \land Y = 1 \Rightarrow I \)
- \( [I \land X \neq 0 \land (X = n)] Y := Y \times X; X := X - 1 \ [I \land (X < n)] \)
- \( I \land \neg(X \neq 0) \Rightarrow Y = x! \)
- \( I \land X \neq 0 \Rightarrow X \geq 0 \)

Informally: total correctness = partial correctness + termination.

This is captured formally by:

- If \( \vdash \{P\} C \{Q\} \) and \( \vdash \{P\} C \{T\} \), then \( \vdash \{P\} C \{Q\} \).
- If \( \vdash \{P\} C \{Q\} \), then \( \vdash \{P\} C \{Q\} \).

Termination is usually straightforward to show, but there are examples where it is not: no one knows whether the program below terminates for all values of \( X \):

\[
\text{while } X > 1 \text{ do }
\begin{align*}
\text{if } \text{ODD}(X) & \text{ then } X := 3 \times X + 1 \\
\text{else } & \quad X := X \text{ DIV } 2
\end{align*}
\]

Microsoft’s T2 tool is used to prove termination of systems code.

We have given rules for total correctness, similar to those for partial correctness.

Only the loop rule differs: the premises of the loop rule require that the loop body decreases a non-negative expression.

It is even possible to do amortised, asymptotic complexity analysis in Hoare logic:

- A Fistful of Dollars, Armaël Guéneau et al., ESOP 2018
Consider an extension of our language with the following form of functions:

\[ C ::= \ldots \mid \text{let } F(X_1, \ldots, X_n) = C_1 \text{ in } C_2 \mid F(X_1, \ldots, X_n) \]

For this to work, we need to be careful to not have aliasing between program variables. We will elide this.

\[
\begin{align*}
\{X = x \land x > 0\} \\
\text{let } F(X, N) = \\
\ \ \ \ \ (\text{if } X > 1 \text{ then } (X := X - 1; N := N \times X; F(X, N)) \text{ else skip}) \text{ in} \\
\ \ \ \ \ N := X; \\
\ \ \ \ \ F(X, N) \\
\{N = \text{fact}(x)\}
\end{align*}
\]

Recursive function pre- and postconditions are like loop invariants, but with a “gap”.

\[
\begin{align*}
\{X = x \land x > 0\} \\
\text{let } F(X, N) = \\
\ \ \ \ \ \{X > 0 \ast N = X \times \ldots \times x\} \\
\ \ \ \ \ (\text{if } X > 1 \text{ then } (X := X - 1; N := N \times X; F(X, N)) \text{ else skip}) \text{ in} \\
\ \ \ \ \ \{X = 1 \ast N = 1 \times \ldots \times x\} \\
\ \ \ \ \ N := X; \\
\ \ \ \ \ F(X, N) \\
\{N = \text{fact}(x)\}
\end{align*}
\]
Concurrent composition

Consider an extension of our WHILE language with a concurrent composition construct (also ’parallel composition’), $C_1 \parallel C_2$, which executes the two statements $C_1$ and $C_2$ concurrently.

For our simple form of concurrency, the statement $C_1 \parallel C_2$ reduces by interleaving execution steps of $C_1$ and $C_2$, until both have terminated:

$$\langle C_1, \langle s, h \rangle \rangle \rightarrow \langle C'_1, \langle s', h' \rangle \rangle$$

$$\langle C_1 \parallel C_2, (s, h) \rangle \rightarrow \langle C'_1 \parallel C_2, (s', h') \rangle$$

$$\langle C_2, \langle s, h \rangle \rangle \rightarrow \langle C'_2, \langle s', h' \rangle \rangle$$

$$\langle C_1 \parallel C_2, (s, h) \rangle \rightarrow \langle C_1 \parallel C'_2, \langle s', h' \rangle \rangle$$

For instance, $(X := 0 \parallel X := 1); \text{print}(X)$ is allowed to print 0 or 1.

Final states are now of the form $F ::= \text{skip} | F_1 \parallel F_2$.

Concurrency disciplines

Adding concurrency complicates reasoning by introducing the possibility of concurrent interference on shared state.

While separation logic does extend to reason about general concurrent interference, we will focus on two common idioms of concurrent programming with limited forms of interference:

• disjoint concurrency, and
• well-synchronised shared state.

Disjoint concurrency
Disjoint concurrency

Disjoint concurrency refers to multiple commands potentially executing concurrently, but all working on disjoint state.

Parallel implementations of divide-and-conquer algorithms can often be expressed using disjoint concurrency.

For instance, in a parallel merge sort, the recursive calls to merge sort operate on disjoint parts of the underlying array.

Disjoint concurrency example

Here is a simple example to illustrate two parallel increment operations that operate on disjoint parts of the heap:

\[
\begin{align*}
\{ X \mapsto 3 \} & \quad \{ Y \mapsto 4 \} \\
\{ X \mapsto 3 \} & \quad \{ Y \mapsto 4 \} \\
A := [X]; [X] := A + 1 & \quad B := [Y]; [Y] := B + 1 \\
\{ X \mapsto 4 \} & \quad \{ Y \mapsto 5 \} \\
\{ X \mapsto 4 \} & \quad \{ Y \mapsto 5 \} \\
\{ X \mapsto 4 \} & \quad \{ Y \mapsto 5 \} \\
\{ X \mapsto 4 \} & \quad \{ Y \mapsto 5 \} 
\end{align*}
\]

Well-synchronised concurrency

The proof rule for disjoint concurrency requires us to split our assertions into two disjoint parts, \( P_1 \) and \( P_2 \), and give each parallel command ownership of one of them:

\[
\begin{align*}
\vdash \{ P_1 \} C_1 \{ Q_1 \} & \quad \vdash \{ P_2 \} C_2 \{ Q_2 \} \\
\text{mod}(C_1) \cap FV(P_2, Q_2) = \emptyset & \quad \text{mod}(C_2) \cap FV(P_1, Q_1) = \emptyset \\
\vdash \{ P_1 \ast P_2 \} C_1\|C_2 \{ Q_1 \ast Q_2 \} 
\end{align*}
\]

The third hypothesis ensures that \( C_1 \) does not modify any program variables used in the specification of \( C_2 \), the fourth hypothesis ensures the symmetric.
Well-synchronised shared state

Well-synchronised shared state refers to the common concurrency idiom of using locks to ensure exclusive access to state shared between multiple threads.

To reason about locking, concurrent separation logic extends separation logic with **lock invariants** that describe the resources protected by locks.

When acquiring a lock, the acquiring thread takes ownership of the lock invariant and when releasing the lock, must give back ownership of the lock invariant.

Well-synchronised shared state example

To illustrate, consider a simplified setting with a single global lock.

We write \( I \vdash \{ P \} \ C \ \{ Q \} \) to indicate that we can derive the given triple assuming the lock invariant is \( I \). We have the following rules:

\[
\begin{align*}
FV(I) &= \emptyset \quad & FV(I) &= \emptyset \\
I \vdash \{ \text{emp} \} \ lock \ \{ I \# \ locked \} \quad & I \vdash \{ I \# \ locked \} \ unlock \ \{ \text{emp} \}
\end{align*}
\]

The *locked* resource ensures the lock can only be unlocked by the thread that currently has the lock.

Well-synchronised shared state example

First, we need to define a lock invariant.

The lock invariant needs to own the shared heap cell at location \( X \) and should express that it always contains an even number:

\[
I \equiv \exists n. x \mapsto 2 \times n
\]

We have to use an indirection through \( X = x \) because \( I \) is not allowed to mention program variables.
Well-synchronised shared state example

\[
\begin{align*}
\{ X = x \land emp \} & \quad \{ X = x \land emp \} \quad \{ X = x \land emp \} \\
\text{lock;} & \quad \text{lock;} & \quad \text{lock;} \\
\{ X = x \land (\exists n. x \mapsto 2 \times n) \land locked \} & \quad \{ X = x \land I \ast locked \} \\
A := [X]; [X] := A + 1; & \quad C := [X]; [X] := C + 2; \\
\{ X = x \land (\exists n. x \mapsto 2 \times n + 1) \land locked \} & \quad \{ X = x \land I \ast locked \} \\
B := [X]; [X] := B + 1; & \quad \text{unlock;} \\
\{ X = x \land (\exists n. x \mapsto 2 \times n) \land locked \} & \quad \{ X = x \land I \ast locked \} \\
\{ X = x \land I \ast locked \} & \quad \text{unlock;} \\
\{ X = x \land emp \} & \quad \{ X = x \land emp \} \\
\text{unlock;} & \quad \text{unlock;} \\
\{ X = x \land emp \} & \quad \{ X = x \land emp \}
\end{align*}
\]

We can temporarily violate the invariant when holding the lock.

Summary of concurrent separation logic

We have seen how concurrent separation logic supports reasoning about concurrent programs.

The rule for disjoint concurrency enables reasoning about the parts of the state that are not shared, and the rules for locks enable reasoning about the parts of the state that are shared but guarded by locks.

Concurrent separation logic can also be extended to support reasoning about general concurrency interference.

We have seen that Hoare logic (separation logic, when we have pointers) enables specifying and reasoning about programs.

Reasoning remains close to the syntax, and captures the intuitions we have about why programs are correct.

It's all about invariants!
