# L101: Less supervision?

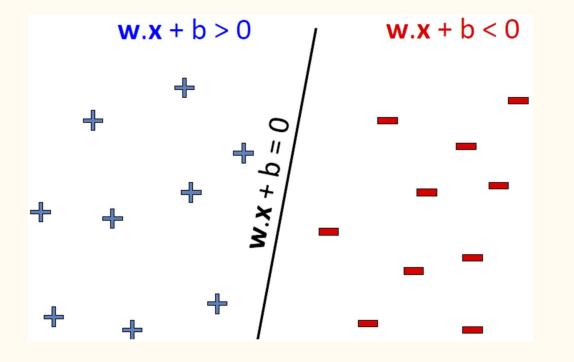

# So far: supervised learning

Why?

- Training models using real outputs for the task you want to solve has better chances of success
- Even if we didn't need labeled data for training, we still want to know how good our model is before deploying it

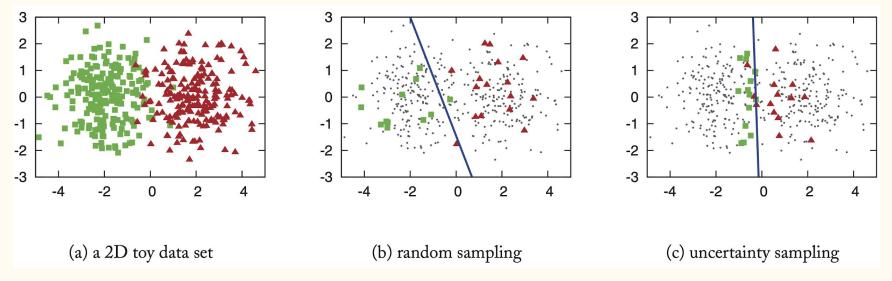

But it needs labeled data for training, how can we help ourselves given that we can only find unlabeled data for free (usually!)

#### Do we need all that labeled data for training?

- Are all instances equally useful in learning a model?
- Let the algorithm decide!
  - Typically select a few instances to label, update model, repeat
- Active learning in education refers to the student asking questions

#### Active learning works

- Savings against randomly selected training data can be impressive
- In fact <u>less can be better</u> (sometimes)
- But this is not always the case (more later)

# Active learning setups

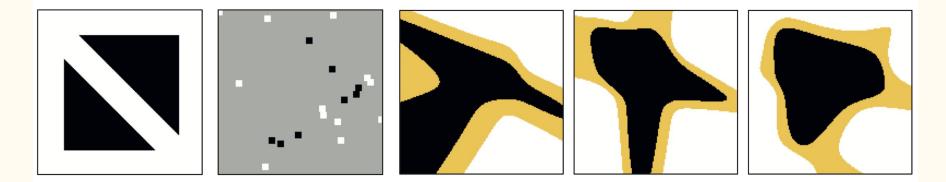

- Pool-based
  - we have a fixed pool of unlabeled data and iterate through it
  - most common: we get some unlabelled instances and need to build a model
- Streaming/online:
  - $\circ$   $\;$  decide whether to ask for a label now or never
  - $\circ$  ask a customer if the transaction is fraudulent, if the e-mail is spam, etc.
- Constructing instances:
  - $\circ$  generate instances for labeling
  - very rare in NLP; need very good generative models
  - <u>first paper</u> just appeared
- Feature-based active learning
  - label features instead of instances

#### How to choose informative instances?

(assuming multiclass classification task)

- Uncertainty based sampling
  - Least confident: pick the instances with the lowest score by the model for any label
  - Margin: pick the instances with the smallest scoring margin between the top-2 labels
  - Entropy in the label distribution (for probabilistic models)
- Query by committee: train a few models and select the instances where they disagree the most
- Meta-learning: learn a model to select the most useful instances (pool, stream)

### Things can go wrong

(a) target function (b) initial sample

(c) uncertainty-based selective sampling over time

What would you do to avoid this?

- Make sure your initial sample is representative?
- Select instances at random too?

#### When not to active learn

- If we need data for evaluation
  - it should be obvious that AL biases the data, no longer representative of the task
- If we don't think the model(s) we have can give good estimates of uncertainty
- If we want to change models later
  - Data selected by one model <u>can be worse than random</u> for another

# Bandit learning

Some times obtaining a complete label for an instance is impossible: e.g. for a search query we need to check all webpages

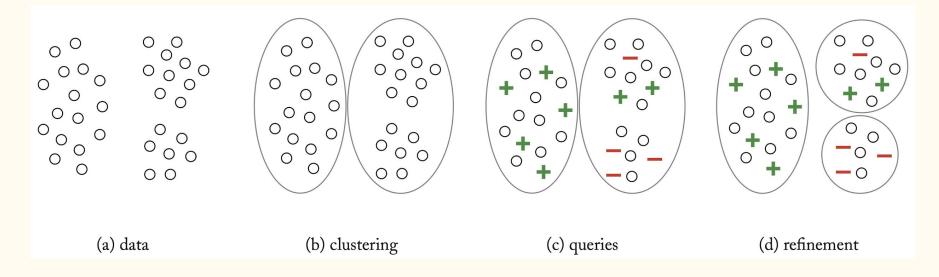

Repeat:

- pick the most promising handle
   (= label)
- get a reward for that handle
- Update using the reward

The key here is how to define promising: a balance of exploration/exploitation Can be adaptive: first explore, then exploit

#### Can we use the unlabeled data to help?

Yes, with clustering!

Hierarchical sampling: prefer instances from clusters that are impure

# Clustering

Many good algorithms:

- K-means (++)
- Gaussian mixture models
- Spectral clustering
- Topic models can be thought of as soft clustering

They are great to explore unlabeled data and learn about theirs properties, but

Hard to evaluate...

<u>Clustering: Science or Art</u>: "the major obstacle is the difficulty in evaluating a clustering algorithm without taking into account the context"

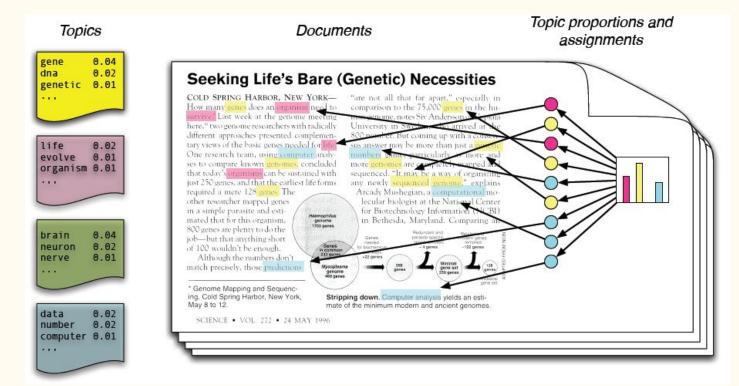

# Unsupervised NLP evaluation

Unsupervised tagger output												
1	2	3 4		1	5	What						
There	are	70	childre	n ther	е.							
CCG gold standard												
NP	<i>(S</i> )	(S\NP)/NP		J/N	N	(S NP) (S NP)						
There		are		70	childrer	n there						

Why PoS tagging and not CCG super-tagging?

So no point in doing unsupervised learning? No, but you need to put it in **context** to evaluate it

#### Topic models

# Topic modeling evaluation (<u>reading tea leaves</u>)

<ul> <li>1 / 10</li> <li>floppy alphabet computer processor</li> <li>2 / 10</li> <li>molecule education study university</li> </ul>	6 / 10 DOUGLAS_HOFSTADTER Douglas Richard Hofstadter (born February 15, 1945 in New York, New York) is an American academic whose research focuses on consciousness, thinking and creativity. He is best known for ", first published in Show entire excerpt							
3 / 10	student	school	study	education	research	university	science	learn

- Word intrusion: Pick a topic, take top-5 words, throw in a low-prob word for the topic, ask humans to spot the intruder
- Topic intrusion: Pick a document, take its top-3 topics, throw in a low-prob topic for the document, ask humans to spot the intruder

#### But isn't unsupervised learning common?

- Yes: in the last ACL 46/661 had "unsupervised" in the title
- But often this is not what unsupervised in the ML sense (no labeled data, e.g. in clustering no cluster info, in topic models no topic info):
  - Some supervision gets in through dictionaries, mapping to labels, etc.
  - Or supervision was readily available
  - Some dev set was most likely used (hopefully not the test set!)
  - Nothing wrong with this; in fact it is a great way to solve tasks
  - $\circ$  But if we want labels in the output we need to provide them

#### What about language modeling?

- Supervised or unsupervised learning?
- For me it supervised, but we can harvest data for it at will
- More data beats better model
- The main application of LMs for a while was to score outputs from MT, ASR, etc.
- Nowadays?

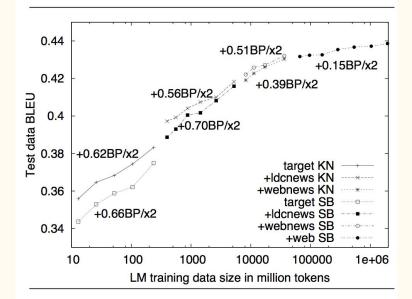

Figure 5: BLEU scores for varying amounts of data using Kneser-Ney (KN) and Stupid Backoff (SB).

#### Brants et al. (2007)

# Word Embeddings

- Once a by-product of learning RNN-based language models, now a goal in itself
- That's the key insight of the <u>word2vec</u> paper: stop worrying about trying to build a language model, focus on the embeddings
- Supervised or unsupervised?
- Unsupervised: LM has a supervised training objective, but we don't have gold standard embeddings:
  - $\circ$   $\;$  This is also why their evaluation is difficult
  - Often done in context: input for supervised models (e.g. <u>BERT</u>)

### Language models as models for task X?

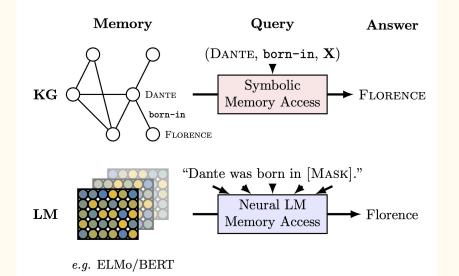

Figure 1: Querying knowledge bases (KB) and language models (LM) for factual knowledge.

#### <u>Petroni et al. (2019)</u>

- Yes! But usually we need to add a bit task-specific supervision
- If our task can be modelled as an LM, we can take advantage of a lot of data and pre-trained models
- If we are building task-specific models, we'd better improve on it!
- If we developing a task/dataset, make sure a LM can't solve it (easily), e.g. don't use an LM alone to construct it
