

# Topics in Logic and Complexity

## Handout 4

Anuj Dawar

<http://www.cl.cam.ac.uk/teaching/2122/L15>

# Expressive Power of Logics

We have seen that the expressive power of *first-order logic*, in terms of computational complexity is *weak*.

*Second-order logic* allows us to express all properties in the *polynomial hierarchy*.

Are there interesting logics intermediate between these two?

We have seen one—*monadic second-order logic*.

We now examine another—*LFP*—the logic of *least fixed points*.

# Inductive Definitions

LFP is a logic that formalises *inductive definitions*.

*Unlike in second-order logic, we cannot quantify over arbitrary relations, but we can build new relations inductively.*

Inductive definitions are pervasive in mathematics and computer science.

The *syntax* and *semantics* of various formal languages are typically defined inductively.

*viz. the definitions of the syntax and semantics of first-order logic seen earlier.*

# Transitive Closure

The *transitive closure* of a binary relation  $E$  is the *smallest* relation  $T$  satisfying:

- $E \subseteq T$ ; and
- if  $(x, y) \in T$  and  $(y, z) \in E$  then  $(x, z) \in T$ .

This constitutes an *inductive definition* of  $T$  and, as we have already seen, there is no *first-order* formula that can define  $T$  in terms of  $E$ .

# Monotone Operators

In order to introduce LFP, we briefly look at the theory of *monotone operators*, in our restricted context.

We write  $\text{Pow}(A)$  for the powerset of  $A$ .

An operator on  $A$  is a function

$$F : \text{Pow}(A) \rightarrow \text{Pow}(A).$$

$F$  is *monotone* if

$$\text{if } S \subseteq T, \text{ then } F(S) \subseteq F(T).$$

# Least and Greatest Fixed Points

A *fixed point* of  $F$  is any set  $S \subseteq A$  such that  $F(S) = S$ .

$S$  is the *least fixed point* of  $F$ , if for all fixed points  $T$  of  $F$ ,  $S \subseteq T$ .

$S$  is the *greatest fixed point* of  $F$ , if for all fixed points  $T$  of  $F$ ,  $T \subseteq S$ .

# Least and Greatest Fixed Points

For any monotone operator  $F$ , define the collection of its *pre-fixed points* as:

$$Pre = \{S \subseteq A \mid F(S) \subseteq S\}.$$

*Note:*  $A \in Pre$ .

Taking

$$L = \bigcap Pre,$$

we can show that  $L$  is a fixed point of  $F$ .

# Fixed Points

For any set  $S \in Pre$ ,

$$L \subseteq S$$

$$F(L) \subseteq F(S)$$

$$F(L) \subseteq S$$

$$F(L) \subseteq L$$

$$F(F(L)) \subseteq F(L)$$

$$F(L) \in Pre$$

$$L \subseteq F(L)$$

*by definition of  $L$ .*

*by monotonicity of  $F$ .*

*by definition of  $Pre$ .*

*by definition of  $L$ .*

*by monotonicity of  $F$*

*by definition of  $Pre$ .*

*by definition of  $L$ .*

# Least and Greatest Fixed Points

$L$  is a *fixed point* of  $F$ .

Every fixed point  $P$  of  $F$  is in  $Pre$ , and therefore  $L \subseteq P$ .

Thus,  $L$  is the least fixed point of  $F$

Similarly, the greatest fixed point is given by:

$$G = \bigcup \{S \subseteq A \mid S \subseteq F(S)\}.$$

# Iteration

Let  $A$  be a *finite* set and  $F$  be a *monotone* operator on  $A$ .  
Define for  $i \in \mathbb{N}$ :

$$\begin{aligned} F^0 &= \emptyset \\ F^{i+1} &= F(F^i). \end{aligned}$$

For each  $i$ ,  $F^i \subseteq F^{i+1}$  (proved by induction).

# Iteration

Proof by induction.

$$\emptyset = F^0 \subseteq F^1.$$

If  $F^i \subseteq F^{i+1}$  then, by monotonicity

$$F(F^i) \subseteq F(F^{i+1})$$

and so  $F^{i+1} \subseteq F^{i+2}$ .

## Fixed-Point by Iteration

If  $A$  has  $n$  elements, then

$$F^n = F^{n+1} = F^m \quad \text{for all } m > n$$

Thus,  $F^n$  is a fixed point of  $F$ .

Let  $P$  be any fixed point of  $F$ . We can show by induction on  $i$ , that  $F^i \subseteq P$ .

$$F^0 = \emptyset \subseteq P$$

If  $F^i \subseteq P$  then

$$F^{i+1} = F(F^i) \subseteq F(P) = P.$$

Thus  $F^n$  is the *least fixed point* of  $F$ .

## Defined Operators

Suppose  $\phi$  contains a relation symbol  $R$  (of arity  $k$ ) not interpreted in the structure  $\mathbb{A}$  and let  $\mathbf{x}$  be a tuple of  $k$  free variables of  $\phi$ .

For any relation  $P \subseteq A^k$ ,  $\phi$  defines a new relation:

$$F_P = \{\mathbf{a} \mid (\mathbb{A}, P) \models \phi[\mathbf{a}]\}.$$

The operator  $F_\phi : \text{Pow}(A^k) \rightarrow \text{Pow}(A^k)$  defined by  $\phi$  is given by the map

$$P \mapsto F_P.$$

Or,  $F_{\phi, \mathbf{b}}$  if we fix parameters  $\mathbf{b}$ .

# Positive Formulas

## Definition

A formula  $\phi$  is *positive* in the relation symbol  $R$ , if every occurrence of  $R$  in  $\phi$  is within the scope of an even number of negation signs.

## Lemma

For any structure  $\mathbb{A}$  not interpreting the symbol  $R$ , any formula  $\phi$  which is positive in  $R$ , and any tuple  $\mathbf{b}$  of elements of  $A$ , the operator  $F_{\phi, \mathbf{b}} : \text{Pow}(A^k) \rightarrow \text{Pow}(A^k)$  is monotone.

# Syntax of LFP

- Any relation symbol of arity  $k$  is a predicate expression of arity  $k$ ;
- If  $R$  is a relation symbol of arity  $k$ ,  $\mathbf{x}$  is a tuple of variables of length  $k$  and  $\phi$  is a formula of LFP in which the symbol  $R$  only occurs positively, then

$$\mathbf{lfp}_{R,\mathbf{x}}\phi$$

is a predicate expression of LFP of arity  $k$ .

All occurrences of  $R$  and variables in  $\mathbf{x}$  in  $\mathbf{lfp}_{R,\mathbf{x}}\phi$  are *bound*

# Syntax of LFP

- If  $t_1$  and  $t_2$  are terms, then  $t_1 = t_2$  is a formula of LFP.
- If  $P$  is a predicate expression of LFP of arity  $k$  and  $\mathbf{t}$  is a tuple of terms of length  $k$ , then  $P(\mathbf{t})$  is a formula of LFP.
- If  $\phi$  and  $\psi$  are formulas of LFP, then so are  $\phi \wedge \psi$ , and  $\neg\phi$ .
- If  $\phi$  is a formula of LFP and  $x$  is a variable then,  $\exists x\phi$  is a formula of LFP.

# Semantics of LFP

Let  $\mathbb{A} = (A, \mathcal{I})$  be a structure with universe  $A$ , and an interpretation  $\mathcal{I}$  of a fixed vocabulary  $\sigma$ .

Let  $\phi$  be a formula of LFP, and  $\iota$  an interpretation in  $A$  of all the free variables (*first or second* order) of  $\phi$ .

To each individual variable  $x$ ,  $\iota$  associates an element of  $A$ , and to each  $k$ -ary relation symbol  $R$  in  $\phi$  that is not in  $\sigma$ ,  $\iota$  associates a relation  $\iota(R) \subseteq A^k$ .

$\iota$  is extended to terms  $t$  in the usual way.

For constants  $c$ ,  $\iota(c) = \mathcal{I}(c)$ .

$\iota(f(t_1, \dots, t_n)) = \mathcal{I}(f)(\iota(t_1), \dots, \iota(t_n))$

# Semantics of LFP

- If  $R$  is a relation symbol in  $\sigma$ , then  $\iota(R) = \mathcal{I}(R)$ .
- If  $P$  is a predicate expression of the form  $\mathbf{lfp}_{R,x}\phi$ , then  $\iota(P)$  is the relation that is the least fixed point of the monotone operator  $F$  on  $A^k$  defined by:

$$F(X) = \{a \in A^k \mid \mathbb{A} \models \phi[\iota\langle X/R, x/a \rangle],$$

where  $\iota\langle X/R, x/a \rangle$  denotes the interpretation  $\iota'$  which is just like  $\iota$  *except* that  $\iota'(R) = X$ , and  $\iota'(x) = a$ .

# Semantics of LFP

- If  $\phi$  is of the form  $t_1 = t_2$ , then  $\mathbb{A} \models \phi[i]$  if,  $\imath(t_1) = \imath(t_2)$ .
- If  $\phi$  is of the form  $R(t_1, \dots, t_k)$ , then  $\mathbb{A} \models \phi[i]$  if,

$$(\imath(t_1), \dots, \imath(t_k)) \in \imath(R).$$

- If  $\phi$  is of the form  $\psi_1 \wedge \psi_2$ , then  $\mathbb{A} \models \phi[i]$  if,  $\mathbb{A} \models \psi_1[i]$  *and*  $\mathbb{A} \models \psi_2[i]$ .
- If  $\phi$  is of the form  $\neg\psi$  then,  $\mathbb{A} \models \phi[i]$  if,  $\mathbb{A} \not\models \psi[i]$ .
- If  $\phi$  is of the form  $\exists x\psi$ , then  $\mathbb{A} \models \phi[i]$  if there is an  $a \in A$  such that  $\mathbb{A} \models \psi[\imath\langle x/a \rangle]$ .

# Transitive Closure

The formula (with free variables  $u$  and  $v$ )

$$\theta \equiv \text{lfp}_{T,xy}[(x = y \vee \exists z(E(x, z) \wedge T(z, y)))](u, v)$$

defines the *reflexive and transitive closure* of the relation  $E$ .

Thus  $\forall u \forall v \theta$  defines *connectedness*.

The expressive power of LFP properly extends that of first-order logic.

# Greatest Fixed Points

If  $\phi$  is a formula in which the relation symbol  $R$  occurs *positively*, then the *greatest fixed point* of the monotone operator  $F_\phi$  defined by  $\phi$  can be defined by the formula:

$$\neg[\text{Ifp}_{R,x} \neg\phi(R/\neg R)](x)$$

where  $\phi(R/\neg R)$  denotes the result of replacing all occurrences of  $R$  in  $\phi$  by  $\neg R$ .

*Exercise:* Verify!.

# Simultaneous Inductions

We are given two formulas  $\phi_1(S, T, x)$  and  $\phi_2(S, T, y)$ ,  
 $S$  is  $k$ -ary,  $T$  is  $l$ -ary.

The pair  $(\phi_1, \phi_2)$  can be seen as defining a map:

$$F : \text{Pow}(A^k) \times \text{Pow}(A^l) \rightarrow \text{Pow}(A^k) \times \text{Pow}(A^l)$$

If both formulas are positive in both  $S$  and  $T$ , then there is a least fixed point.

$$(P_1, P_2)$$

defined by *simultaneous induction* on  $\mathbb{A}$ .

# Simultaneous Inductions

## Theorem

For any pair of formulas  $\phi_1(S, T)$  and  $\phi_2(S, T)$  of LFP, in which the symbols  $S$  and  $T$  appear only positively, there are formulas  $\phi_S$  and  $\phi_T$  of LFP which, on any structure  $\mathbb{A}$  containing at least two elements, define the two relations that are defined on  $\mathbb{A}$  by  $\phi_1$  and  $\phi_2$  by simultaneous induction.

# Proof

Assume  $k \leq l$ .

We define  $P$ , of arity  $l + 2$  such that:

$(c, d, a_1, \dots, a_l) \in P$  if, and only if, either  $c = d$  and  $(a_1, \dots, a_k) \in P_1$  or  $c \neq d$  and  $(a_1, \dots, a_l) \in P_2$

For new variables  $x_1$  and  $x_2$  and a new  $l + 2$ -ary symbol  $R$ , define  $\phi'_1$  and  $\phi'_2$  by replacing all occurrences of  $S(t_1, \dots, t_k)$  by:

$$x_1 = x_2 \wedge \exists y_{k+1}, \dots, \exists y_l R(x_1, x_2, t_1, \dots, t_k, y_{k+1}, \dots, y_l),$$

and replacing all occurrences of  $T(t_1, \dots, t_l)$  by:

$$x_1 \neq x_2 \wedge R(x_1, x_2, t_1, \dots, t_l).$$

# Proof

Define  $\phi$  as

$$(x_1 = x_2 \wedge \phi'_1) \vee (x_1 \neq x_2 \wedge \phi'_2).$$

Then,

$$(\text{Ifp}_{R, x_1 x_2 y} \phi)(x, x, y)$$

defines  $P$ , so

$$\phi_S \equiv \exists x \exists y_{k+1}, \dots, \exists y_l (\text{Ifp}_{R, x_1 x_2 y} \phi)(x, x, y);$$

and

$$\phi_T \equiv \exists x_1 \exists x_2 (x_1 \neq x_2 \wedge \text{Ifp}_{R, x_1 x_2 y} \phi)(x_1, x_2, y).$$

# Complexity of LFP

Any *query* definable in LFP is decidable by a *deterministic* machine in *polynomial time*.

To be precise, we can show that for each formula  $\phi$  there is a  $t$  such that

$$\mathbb{A} \models \phi[a]$$

is decidable in time  $O(n^t)$  where  $n$  is the number of elements of  $\mathbb{A}$ .

We prove this by induction on the structure of the formula.

# Complexity of LFP

- Atomic formulas by direct lookup ( $O(n^a)$  time, where  $a$  is the maximum arity of any predicate symbol in  $\sigma$ ).
- Boolean connectives are easy.  
*If  $\mathbb{A} \models \phi_1$  can be decided in time  $O(n^{t_1})$  and  $\mathbb{A} \models \phi_2$  in time  $O(n^{t_2})$ , then  $\mathbb{A} \models \phi_1 \wedge \phi_2$  can be decided in time  $O(n^{\max(t_1, t_2)})$*
- If  $\phi \equiv \exists x \psi$  then for each  $a \in \mathbb{A}$  check whether

$$(\mathbb{A}, c \mapsto a) \models \psi[c/x],$$

where  $c$  is a new constant symbol. If  $\mathbb{A} \models \psi$  can be decided in time  $O(n^t)$ , then  $\mathbb{A} \models \phi$  can be decided in time  $O(n^{t+1})$ .

# Complexity of LFP

Suppose  $\phi \equiv [\text{Ifp}_{R,x}\psi](t)$  ( $R$  is  $l$ -ary)

To decide  $\mathbb{A} \models \phi[a]$ :

$R := \emptyset$

**for**  $i := 1$  **to**  $n^l$  **do**

$R := F_\psi(R)$

**end**

**if**  $a \in R$  **then** accept **else** reject

# Complexity of LFP

To compute  $F_\psi(R)$

*For every tuple  $\mathbf{a} \in A^I$ , determine whether  $(\mathbb{A}, R) \models \psi[\mathbf{a}]$ .*

If deciding  $(\mathbb{A}, R) \models \psi$  takes time  $O(n^t)$ , then each assignment to  $R$  inside the loop requires time  $O(n^{I+t})$ . The total time taken to execute the loop is then  $O(n^{2I+t})$ . Finally, the last line can be done by a search through  $R$  in time  $O(n^I)$ . The total running time is, therefore,  $O(n^{2I+t})$ .

The *space* required is  $O(n^I)$ .

# Capturing P

For any  $\phi$  of LFP, the language  $\{[\mathbb{A}]_< \mid \mathbb{A} \models \phi\}$  is in P.

Suppose  $\rho$  is a signature that contains a *binary relation symbol*  $<$ , possibly along with other symbols.

Let  $\mathcal{O}_\rho$  denote those structures  $\mathbb{A}$  in which  $<$  is a *linear order* of the universe.

For any language  $L \in P$ , there is a sentence  $\phi$  of LFP that defines the class of structures

$$\{\mathbb{A} \in \mathcal{O}_\rho \mid [\mathbb{A}]_< \in L\}$$

(Immerman; Vardi 1982)

# Capturing P

Recall the proof of *Fagin's Theorem*, that ESO captures NP.

Given a machine  $M$  and an integer  $k$ , there is a *first-order* formula  $\phi_{M,k}$  such that

$$\mathbb{A} \models \exists < \exists T_{\sigma_1} \cdots T_{\sigma_s} \exists S_{q_1} \cdots S_{q_m} \exists H \phi_{M,k}$$

if, and only if,  $M$  accepts  $[\mathbb{A}]_<$  in time  $n^k$ , for some order  $<$ .

If we *fix* the order  $<$  as part of the structure  $\mathbb{A}$ , we do not need the outermost quantifier.

Moreover, for a *deterministic* machine  $M$ , the relations  $T_{\sigma_1} \cdots T_{\sigma_s}, S_{q_1} \cdots S_{q_m}, H$  can be defined *inductively*.

# Capturing P

$$\begin{aligned} \text{Tape}_a(x, y) \Leftrightarrow & \\ (x = 1 \wedge \text{Init}_a(y)) \vee & \\ \exists t \exists h \bigvee_q & (x = t + 1 \wedge \text{State}_q(t, h) \wedge \\ & [(h = y \wedge \bigvee_{\{b, d, q' \mid \Delta(q, b, q', a, d)\}} \text{Tape}_b(t, y) \vee \\ & h \neq y \wedge \text{Tape}_a(t, y)])]; \end{aligned}$$

where  $\text{Init}_a(y)$  is the formula that defines the positions in which the symbol  $a$  appears in the input.

# Capturing P

$$\begin{aligned} \text{State}_q(x, y) \Leftrightarrow & \\ (x = 1 \wedge y = 1 \wedge q = q_0) \vee & \\ \exists t \exists h \quad \bigvee_{\{a, b, q' \mid \Delta(q', a, q, b, R)\}} & (x = t + 1 \wedge \text{State}_{q'}(t, h) \wedge \\ & \text{Tape}_a(t, h) \wedge y = h + 1) \vee \\ \bigvee_{\{a, b, q' \mid \Delta(q', a, q, b, L)\}} & (x = t + 1 \wedge \text{State}'_{q'}(t, h) \wedge \\ & \text{Tape}_a(t, h) \wedge h = y + 1)). \end{aligned}$$

# Unordered Structures

In the absence of an *order relation*, there are properties in  $P$  that are not definable in  $LFP$ .

There is no sentence of  $LFP$  which defines the structures with an *even* number of elements.

# Evenness

Let  $\mathcal{E}$  be the collection of all structures in the empty signature.

In order to prove that *evenness* is not defined by any LFP sentence, we show the following.

## Lemma

For every LFP formula  $\phi$  there is a first order formula  $\psi$ , such that for all structures  $\mathbb{A}$  in  $\mathcal{E}$ ,  $\mathbb{A} \models (\phi \leftrightarrow \psi)$ .

# Unordered Structures

Let  $\psi(x, y)$  be a first order formula.

$\text{fp}_{R,x}\psi$  defines the relation

$$F_{\psi,b}^{\infty} = \bigcup_{i \in \mathbb{N}} F_{\psi,b}^i$$

for a fixed interpretation of the variables  $y$  by the tuple of parameters  $b$ .  
For each  $i$ , there is a first order formula  $\psi^i$  such that on any structure  $\mathbb{A}$ ,

$$F_{\psi,b}^i = \{a \mid \mathbb{A} \models \psi^i[a, b]\}.$$

# Defining the Stages

These formulas are obtained by *induction*.

$\psi^1$  is obtained from  $\psi$  by replacing all occurrences of subformulas of the form  $R(t)$  by  $t \neq t$ .

$\psi^{i+1}$  is obtained by replacing in  $\psi$ , all subformulas of the form  $R(t)$  by  $\psi^i(t, y)$

Let  $\mathbf{b}$  be an  $l$ -tuple, and  $\mathbf{a}$  and  $\mathbf{c}$  two  $k$ -tuples in a structure  $\mathbb{A}$  such that *there is an automorphism  $\iota$  of  $\mathbb{A}$*  (i.e. an *isomorphism* from  $\mathbb{A}$  to itself) such that

- $\iota(\mathbf{b}) = \mathbf{b}$
- $\iota(\mathbf{a}) = \mathbf{c}$

Then,

$$\mathbf{a} \in F_{\psi, \mathbf{b}}^i \quad \text{if, and only if,} \quad \mathbf{c} \in F_{\psi, \mathbf{b}}^i.$$

# Bounding the Induction

This defines an *equivalence relation*  $a \sim_b c$ .

If there are  $p$  distinct equivalence classes, then

$$F_{\psi, b}^{\infty} = F_{\psi, b}^p$$

In  $\mathcal{E}$  there is a uniform bound  $p$ , that does not depend on the size of the structure.
