Memory management

Manual memory management

Memory

Manual memory management: programmer controls (de)allocation time/place:

```
void *malloc(size_t n)    /* allocate n bytes, return address */  
void free(void *addr)    /* relinquish use of memory at addr */
```

The programmer has a lot of **control**. However, **mistakes** can be disastrous:

missing free

```
p = malloc(10);  
return OK;
```

double free

```
free(p);  
free(p);
```

use after free

```
free(p);  
*p += 1;
```

(**Observation**: deallocation is much harder than allocation)

Automatic memory management

Memory

Copying

Generations

Many programming languages support heap allocation
but do not provide a deallocation operation

```
d = dict(x=3,y=4)
```

Python

```
let d = [("x", 3); ("y", 4)]
```

OCaml

Unless the storage is reclaimed *somehow*, memory might be exhausted.

General approach: **automatic memory management** (“garbage collection”)

Memory

Automation is based on an **approximation**:

*If data can be reached from a **root set**, then it is not “garbage”*

The root set might include: the **stack**, **registers**, **global variables**.

(Without loss of generality, assume a *single root*)

Reachability and representations

Memory

Ascertaining reachability requires knowledge of representations:

What is a pointer?

(typical approach: use a *tag bit* to distinguish between pointers and integers)

How are objects laid out?

(typical approach: use *headers* that carry sizes and other metadata)

Reference counting & tracing collection

Memory

Copying

Generations

Two basic approaches (and many variations):

Reference counting

Keep a **reference count** with each object that represents the number of pointers to it.

An object is **garbage when its count is 0**

Tracing garbage collection

Keep alive objects that are **reachable** from the root set (i.e. transitive close of pointer graph)

An object is **garbage when it is unreachable**

Reference counting: idea

Memory

The **reference count** tracks the number of pointers to each object.

An object's reference count is 1 when the object is created:

The count is incremented when a pointer newly references the object:

The count is decremented when a pointer no longer references the object:

The object is unreachable garbage when the reference count goes to 0:

Reference counting can't collect cyclic garbage

Memory

Reference counting

Mark & sweep

Copying

Generations

A **significant weakness** of reference counting:

There are no other references to these objects in the program but **the objects will never be collected.**

Long chains of objects make reclamation expensive

Memory

A **significant weakness** of (naive) reference counting:

Reclaiming an object can set off an unboundedly large **chain of reclamations**

Reference counting: advantages and drawbacks

Memory

counting

Mark &
sweep

Copying

Generations

Advantages of reference counting:

- + Collection costs distributed through the computation
- + Allows rapid reclamation and immediate reuse

Drawbacks of reference counting:

- size overhead of storing references
- potentially high/unbounded cost on reclamation
- taking a reference involves (potentially expensive) mutation

Generations

Mark & sweep is a **two-phase** algorithm:

Mark phase: Traverse object graph depth first to **mark live data**

Sweep phase: iterate over entire heap, reclaiming unmarked data

Key idea: identify and reclaim **dead objects**

Advantages of mark & sweep:

- + Reasonably simple
- + Collects cycles
- + Low space overhead

Drawbacks of mark & sweep

- Scans entire heap during sweeping
- Long (multi-second) pauses, inappropriate for interactive applications

Copying collection

Copying collection: overview

Memory

Split heap in two: **from-space** (active), **to-space** (unused)

Reference counting

During garbage collection: **copy** from from-space into to-space

Mark & sweep

After garbage collection: **abandon** dead objects, switch heap roles

Copying

Copying collection: advantages and drawbacks

Memory

Advantages of copying garbage collection:

- + Reasonably simple
- + Collects cycles
- + Has **running time propotional to the number of live objects**
- + **Automatically compacts** memory, eliminating fragmentation
- + Very low allocation costs (pointer bump)

Reference counting

Mark & sweep

Copying

Drawbacks of copying garbage collection

- Uses **twice as much memory** as the program requires

Generations

Generational garbage collection

Generational GC: motivation

Memory

Observation: scanning all live objects takes a long time

Reference counting

Observation: programs often allocate a lot (hundreds of MB per second)

Observation: object lifetimes are mostly very short or relatively long

Mark & sweep

Example **evidence** (much more is available):

> 98% of collected garbage had been allocated and discarded since previous collection
(Foderaro and Fateman, 1981)

80 – 98% of objects die before 1MB old
(Wilson, 1994)

50 – 90% of Common Lisp objects die before 10KB old
(Zorn, 1989)

Copying

Generations

Memory

Reference
counting

Mark &
sweep

Copying

Key idea: focus on young objects

Mechanism:

- divide heap into 2+ generations

- frequently collect young generations (fast)

- promote surviving objects to old generations

- occasionally collect old generations (slow)

Many **variations** (e.g. generations can use different collection schemes)

Generational GC: advantages & complexities

Memory

Advantages of generational garbage collection:

- + reduce pauses (to $100\mu s$ or less; suitable for interactive programs)
- + avoid wasted time scanning long-lived objects

Mark & sweep

Complexities of generational garbage collection:

- must distinguish between old & young pointers
- hard to find generation roots (consider pointers from old to young objects)
- can use > 2 generations, all with different policies
