# Configuration Graph

Define the *configuration graph* of  $M, x$  to be the graph whose nodes are the possible configurations, and there is an edge from  $i$  to  $j$  if, and only if,  $i \rightarrow_M j$ .

Then,  $M$  accepts  $x$  if, and only if, some accepting configuration is reachable from the starting configuration  $(s, \triangleright, x, \triangleright, \epsilon)$  in the configuration graph of  $M, x$ .

Using the  $O(n^2)$  algorithm for **Reachability**, we get that  $L(M)$ —the language accepted by  $M$ —can be decided by a deterministic machine operating in time

$$c'(nc^{f(n)})^2 \sim c'c^{2(\log n+f(n))} \sim k^{(\log n+f(n))}$$

In particular, this establishes that **NL**  $\subseteq$  **P** and **NPSPACE**  $\subseteq$  **EXP**.

# NL Reachability

We can construct an algorithm to show that the **Reachability** problem is in **NL**:

1. write the index of node  $a$  in the work space;
2. if  $i$  is the index currently written on the work space:
  - 2.1 if  $i = b$  then accept, else  
guess an index  $j$  ( $\log n$  bits) and write it on the work space.
  - 2.2 if  $(i, j)$  is not an edge, reject, else replace  $i$  by  $j$  and return to (2).

# Savitch's Theorem

Further simulation results for nondeterministic space are obtained by other algorithms for **Reachability**.

We can show that **Reachability** can be solved by a *deterministic* algorithm in  $O((\log n)^2)$  space.

Consider the following recursive algorithm for determining whether there is a path from  $a$  to  $b$  of length at most  $i$ .

$O((\log n)^2)$  space Reachability algorithm:

$\text{Path}(a, b, i)$

if  $i = 1$  and  $a \neq b$  and  $(a, b)$  is not an edge reject

else if  $(a, b)$  is an edge or  $a = b$  accept

else, for each node  $x$ , check:

1.  $\text{Path}(a, x, \lfloor i/2 \rfloor)$

2.  $\text{Path}(x, b, \lceil i/2 \rceil)$

if such an  $x$  is found, then accept, else reject.

The maximum depth of recursion is  $\log n$ , and the number of bits of information kept at each stage is  $3 \log n$ .

# Savitch's Theorem

The space efficient algorithm for reachability used on the configuration graph of a nondeterministic machine shows:

$$\text{NSPACE}(f) \subseteq \text{SPACE}(f^2)$$

for  $f(n) \geq \log n$ .

This yields

$$\text{PSPACE} = \text{NSPACE} = \text{co-NPSPACE}.$$

# Complementation

A still more clever algorithm for **Reachability** has been used to show that nondeterministic space classes are closed under complementation:

If  $f(n) \geq \log n$ , then

$$\text{NSPACE}(f) = \text{co-NSPACE}(f)$$

In particular

$$\text{NL} = \text{co-NL}.$$

# Logarithmic Space Reductions

We write

$$A \leq_L B$$

if there is a reduction  $f$  of  $A$  to  $B$  that is computable by a deterministic Turing machine using  $O(\log n)$  workspace (with a *read-only* input tape and *write-only* output tape).

*Note:* We can compose  $\leq_L$  reductions. So,

$$\text{if } A \leq_L B \text{ and } B \leq_L C \text{ then } A \leq_L C$$

# NP-complete Problems

Analysing carefully the reductions we constructed in our proofs of NP-completeness, we can see that SAT and the various other NP-complete problems are actually complete under  $\leq_L$  reductions.

Thus, if  $SAT \leq_L A$  for some problem  $A$  in  $L$  then not only  $P = NP$  but also  $L = NP$ .

## P-complete Problems

It makes little sense to talk of complete problems for the class  $P$  with respect to polynomial time reducibility  $\leq_P$ .

There are problems that are complete for  $P$  with respect to *logarithmic space* reductions  $\leq_L$ .

One example is  $CVP$ —the circuit value problem.

That is, for every language  $A$  in  $P$ ,

$$A \leq_L CVP$$

- If  $CVP \in L$  then  $L = P$ .
- If  $CVP \in NL$  then  $NL = P$ .
