Type Systems

Lecture 8: Using Monads to Control Effects

Neel Krishnaswami
University of Cambridge
let knot : ((int -> int) -> int -> int) -> int -> int =
  fun f ->
    let r = ref (fun n -> 0) in
    let recur = fun n -> !r n in
    let () = r := fun n -> f recur n in
    recur

1. Create a reference holding a function
2. Define a function that forwards its argument to the ref
3. Set the reference to a function that calls \( f \) on the forwarder and the argument \( n \)
4. Now \( f \) will call itself recursively!
Not a Theorem: (Termination) Every well-typed program \( \cdot, \cdot \vdash e : X \) terminates.

- Landin’s knot lets us define recursive functions by backpatching
- As a result, we can write nonterminating programs
- So every type is inhabited, and consistency fails
What is the Problem?

1. We began with the typed lambda calculus
2. We added state as a set of primitive operations
3. We lost consistency
4. Problem: unforeseen interaction between different parts of the language
   • Recursive definitions = state + functions
5. Question: is this a real problem?
What is the Solution?

- Restrict the use of state:
  1. Limit what references can store (eg, only to booleans and integers)
  2. Restrict how references can be referred to (eg, in core safe Rust)
  3. We don’t have time to pursue these in this course

- Mark the use of state:
  - Distinguish between *pure* and *impure* code
  - Impure computations can depend on pure ones
  - Pure computations *cannot* depend upon impure ones
  - A form of *taint tracking*
### Types

\[ X ::= 1 | \mathbb{N} | X \rightarrow Y | \text{ref}X | TX \]

### Pure Terms

\[ e ::= \langle \rangle | n | \lambda x : X. e | e \ e' | l | \{t\} \]

### Impure Terms

\[ t ::= \text{new} \ e | !e | e := e' | \text{let} \ x = e; \ t | \text{return} \ e \]

### Values

\[ v ::= \langle \rangle | n | \lambda x : X. e | l | \{t\} \]

### Stores

\[ \sigma ::= \cdot | \sigma, l : v \]

### Contexts

\[ \Gamma ::= \cdot | \Gamma, x : X \]

### Store Typings

\[ \Sigma ::= \cdot | \Sigma, l : X \]
Typing for Pure Terms

\[
\frac{x : X \in \Gamma}{\Sigma; \Gamma \vdash x : X} \quad \text{HYP} \quad \frac{\emptyset}{\Sigma; \Gamma \vdash \emptyset : 1} \quad 1! \quad \frac{}{\Sigma; \Gamma \vdash n : \mathbb{N}} \quad \mathbb{N}! \\
\frac{}{\Sigma; \Gamma \vdash \langle \rangle : 1} \\
\frac{\Sigma; \Gamma, x : X \vdash e : Y}{\Sigma; \Gamma \vdash \lambda x : X. e : X \rightarrow Y} \rightarrow I \\
\frac{\Sigma; \Gamma \vdash e : X \rightarrow Y \quad \Sigma; \Gamma \vdash e' : X}{\Sigma; \Gamma \vdash e \ e' : Y} \rightarrow E \\
\frac{l : X \in \Sigma}{\Sigma; \Gamma \vdash l : \text{ref} X} \quad \text{REFBAR} \\
\frac{}{\Sigma; \Gamma \vdash \{t\} : TX} \quad T! \\
\]

• Similar to STLC rules + thread $\Sigma$ through all judgements
• New judgement $\Sigma; \Gamma \vdash t \dive X$ for imperative computations
Typing for Effectful Terms

\[ \Sigma; \Gamma \vdash t :: X \]

### Rules:

\[
\begin{align*}
\Sigma; \Gamma \vdash e : X & \quad \text{REFL} \\
\Sigma; \Gamma \vdash \text{new } e :: \text{ref } X & \\
\Sigma; \Gamma \vdash e : \text{ref } X & \\
\Sigma; \Gamma \vdash !e :: X & \quad \text{REFGET} \\
\Sigma; \Gamma \vdash e : \text{ref } X & \\
\Sigma; \Gamma \vdash e' : X & \\
\Sigma; \Gamma \vdash e := e' :: ! & \quad \text{REFSET} \\
\Sigma; \Gamma \vdash e : X & \\
\Sigma; \Gamma \vdash \text{return } e :: X & \quad \text{TRET} \\
\Sigma; \Gamma \vdash e : T X & \\
\Sigma; \Gamma, x : X \vdash t :: Z & \quad \text{TLET} \\
\Sigma; \Gamma \vdash \text{let } x = e; \ t :: Z 
\end{align*}
\]

- We now mark potentially effectful terms in the judgement.
- Note that return \( e \) isn’t effectful – conservative approximation!
A Two-Level Operational Semantics: Pure Part

\[
\begin{align*}
& e_0 \leadsto e_0' \\
\Rightarrow & e_0 e_1 \leadsto e_0' e_1 \\
& e_1 \leadsto e_1' \\
\Rightarrow & v_0 e_1 \leadsto v_0 e_1' \\
& (\lambda x : X. e) v \leadsto [v/x]e
\end{align*}
\]

- Similar to the basic STLC operational rules
- We no longer thread a store \( \sigma \) through each transition!
A Two-Level Operational Semantics: Impure Part, 1/2

\[
\begin{align*}
\text{If } e & \sim e' \text{, then } \\
\langle \sigma; \text{new } e \rangle & \sim \langle \sigma; \text{new } e' \rangle \\
\text{If } e & \sim e' \text{, then } \\
\langle \sigma; ! e \rangle & \sim \langle \sigma; ! e' \rangle \\
\langle \sigma; ! l \rangle & \sim \langle \sigma; \text{return } v \rangle \\
\langle \sigma; v_0 := e_1 \rangle & \sim \langle \sigma; v_0 := e_1' \rangle \\
\langle \sigma; l : v, \sigma' \rangle; l & := v' \sim \langle \sigma, l : v', \sigma' \rangle; \text{return } \langle \rangle \\
\end{align*}
\]
A Two-Level Operational Semantics: Impure Part, 2/2

\[
\begin{align*}
& e \sim e' \\
\quad & \langle \sigma; \text{return } e \rangle \sim \langle \sigma; \text{return } e' \rangle \\
& e \sim e' \\
\quad & \langle \sigma; \text{let } x = e; \ t \rangle \sim \langle \sigma; \text{let } x = e'; \ t \rangle \\
\quad & \langle \sigma; \text{let } x = \{\text{return } v\}; \ t_1 \rangle \sim \langle \sigma; [v/x]t_1 \rangle \\
& \langle \sigma; t_0 \rangle \sim \langle \sigma'; t'_0 \rangle \\
\quad & \langle \sigma; \text{let } x = \{t_0\}; \ t_1 \rangle \sim \langle \sigma'; \text{let } x = \{t'_0\}; \ t_1 \rangle
\end{align*}
\]
Store and Configuration Typing

\[
\begin{align*}
\Sigma & \vdash \sigma' : \Sigma' & \langle \sigma; e \rangle & : \langle \Sigma; X \rangle \\
\Sigma \vdash & \cdot : \cdot & \Sigma \vdash & \sigma' : \Sigma' & \Sigma ; \cdot \vdash & v : X & \Sigma \vdash & (\sigma', l : v) : (\Sigma', l : X) \\
\Sigma \vdash & \sigma : \Sigma & \Sigma ; \cdot \vdash & t \div X & \langle \sigma; t \rangle & : \langle \Sigma; X \rangle
\end{align*}
\]

\textbf{STORENIL} \hspace{1cm} \textbf{STORECONS} \hspace{1cm} \textbf{CONFIGOK}

- Check that all the closed values in the store \( \sigma' \) are well-typed
- Types come from \( \Sigma' \), checked in store \( \Sigma \)
- Configurations are well-typed if the store and term are well-typed
• **Pure Term Weakening:**
  If $\Sigma; \Gamma, \Gamma' \vdash e : X$ then $\Sigma; \Gamma, z : Z, \Gamma' \vdash e : X$.

• **Pure Term Exchange:**
  If $\Sigma; \Gamma, y : Y, z : Z, \Gamma' \vdash e : X$ then $\Sigma; \Gamma, z : Z, y : Y, \Gamma' \vdash e : X$.

• **Pure Term Substitution:**
  If $\Sigma; \Gamma \vdash e : X$ and $\Sigma; \Gamma, x : X \vdash e' : Z$ then $\Sigma; \Gamma \vdash [e/x]e' : Z$. 
• **Effectful Term Weakening:**
  If \( \Sigma; \Gamma, \Gamma' \vdash t \div X \) then \( \Sigma; \Gamma, z : Z, \Gamma' \vdash t \div X \).

• **Effectful Term Exchange:**
  If \( \Sigma; \Gamma, y : Y, z : Z, \Gamma' \vdash t \div X \) then \( \Sigma; \Gamma, z : Z, y : Y, \Gamma' \vdash t \div X \).

• **Effectful Term Substitution:**
  If \( \Sigma; \Gamma \vdash e : X \) and \( \Sigma; \Gamma, x : X \vdash t \div Z \) then \( \Sigma; \Gamma \vdash [e/x]t \div Z \).
1. Prove Pure Term Weakening and Impure Term Weakening mutually inductively
2. Prove Pure Term Exchange and Impure Term Exchange mutually inductively
3. Prove Pure Term Substitution and Impure Term Substitution mutually inductively

Two mutually-recursive judgements $$\rightarrow$$ Two mutually-inductive proofs
Definition (Store extension):
Define $\Sigma \leq \Sigma'$ to mean there is a $\Sigma''$ such that $\Sigma' = \Sigma, \Sigma''$.

Lemma (Store Monotonicity):
If $\Sigma \leq \Sigma'$ then:

1. If $\Sigma; \Gamma \vdash e : X$ then $\Sigma'; \Gamma \vdash e : X$.
2. If $\Sigma; \Gamma \vdash t \div X$ then $\Sigma'; \Gamma \vdash t \div X$.
3. If $\Sigma \vdash \sigma_0 : \Sigma_0$ then $\Sigma' \vdash \sigma_0 : \Sigma_0$.

The proof is by structural induction on the appropriate definition. (Prove 1. and 2. mutually-inductively!)

This property means allocating new references never breaks the typability of a term.
Theorem (Progress):
If $\langle \sigma; t \rangle : \langle \Sigma; X \rangle$ then $t = \text{return } v$ or $\langle \sigma; t \rangle \leadsto \langle \sigma'; t' \rangle$.

Theorem (Preservation):
If $\langle \sigma; t \rangle : \langle \Sigma; X \rangle$ and $\langle \sigma; t \rangle \leadsto \langle \sigma'; t' \rangle$ then there exists $\Sigma' \supseteq \Sigma$ such that $\langle \sigma'; t' \rangle : \langle \Sigma'; X \rangle$.

Proof:

- For progress, induction on derivation of $\Sigma; \cdot \vdash t \div X$
- For preservation, induction on derivation of $\langle \sigma; e \rangle \leadsto \langle \sigma'; e' \rangle$
What Have we Accomplished?

- In the monadic language, pure and effectful code is strictly separated
- As a result, pure programs terminate
- However, we can still write imperative programs
Monads for I/O

Types

\[ X ::= 1 \mid \mathbb{N} \mid X \rightarrow Y \mid T_{IO} X \]

Pure Terms

\[ e ::= \langle \rangle \mid n \mid \lambda x : X. e \mid e e' \mid \{ t \} \]

Impure Terms

\[ t ::= \text{print } e \mid \text{let } x = e; \ t \mid \text{return } e \]

Values

\[ v ::= \langle \rangle \mid n \mid \lambda x : X. e \mid \{ t \} \]

Contexts

\[ \Gamma ::= \cdot \mid \Gamma, x : X \]
Monads for I/O: Typing Pure Terms

\[ \Gamma \vdash e : X \]

\[ x : X \in \Gamma \quad \text{HYP} \]
\[ \Gamma \vdash x : X \]

\[ \Gamma \vdash \langle \rangle : 1 \]
\[ \Gamma \vdash n : \mathbb{N} \]

\[ \Gamma, x : X \vdash e : Y \]
\[ \Gamma \vdash \lambda x : X. e : X \rightarrow Y \quad \rightarrow I \]

\[ \Gamma \vdash e : X \rightarrow Y \]
\[ \Gamma \vdash e' : X \rightarrow E \]

\[ \Gamma \vdash t : X \]
\[ \Gamma \vdash \{t\} : TX \quad \text{Tl} \]

- Similar to STLC rules (no store typing!)
- New judgement \( \Gamma \vdash t \div X \) for imperative computations
• TRET and TLET are identical rules
• Difference is in the operations – print e vs get/set/new
Operational Semantics for I/O: Pure Part

\[
\begin{align*}
  e_0 & \rightsquigarrow e'_0 \\
  e_0 e_1 & \rightsquigarrow e'_0 e_1 \\
  e_1 & \rightsquigarrow e'_1 \\
  v_0 e_1 & \rightsquigarrow v_0 e'_1 \\
  (\lambda x : X. e) v & \rightsquigarrow [v/x]e
\end{align*}
\]

- *Identical* to the pure rules for state!
Operational Semantics for I/O: Impure Part

\[
\begin{align*}
  e \sim e' & \quad \langle \omega; \text{print } e \rangle \sim \langle \omega; \text{print } e' \rangle \\
  e \sim e' & \quad \langle \omega; \text{return } e \rangle \sim \langle \omega; \text{return } e' \rangle \\
  e \sim e' & \quad \langle \omega; \text{let } x = e; \; t \rangle \sim \langle \omega; \text{let } x = e'; \; t \rangle \\
\end{align*}
\]

\[
\langle \omega; \text{let } x = \{\text{return } v\}; \; t_1 \rangle \sim \langle \omega; [v/x]t_1 \rangle
\]

\[
\langle \omega; t_0 \rangle \sim \langle \omega'; t'_0 \rangle \\
\langle \omega; \text{let } x = \{t_0\}; \; t_1 \rangle \sim \langle \omega'; \text{let } x = \{t'_0\}; \; t_1 \rangle
\]

- State is now a list of output tokens
- All rules otherwise identical except for operations
Limitations of Monadic Style: Encapsulating Effects

```ocaml
let fact : int -> int = fun n ->
  let r = ref 1 in
  let rec loop n =
    match n with
    | 0 -> !r
    | n -> let () = r := !r * n in
    loop (n-1)
  in
  loop n

• This function uses local state
• No caller can tell if it uses state or not
• Should it have a pure type, or a monadic type?
```
Limitations of Monadic Style: Encapsulating Effects

```ocaml
let rec find' : ('a -> bool) -> 'a list -> 'a =
  fun p ys ->
    match ys with
    | [] -> raise Not_found
    | y :: ys -> if p y then y else find' p ys

let find : ('a -> bool) -> 'a list -> 'a option =
  fun p xs ->
    try Some (find' p xs)
    with Not_found -> None
```

- `find'` has an effect – it can raise an exception
- But `find` calls `find'`, and catches the exception
- Should `find` have an exception monad in its type?
Suppose you have two programs:

1. `p1 : (int -> ans) state`
2. `p2 : int io`

- We write `a state` for a state monad computation
- We write `b io` for a I/O monad computation
- How do we write a program that does `p2`, and passes its argument to `p1`?
• Java *checked exceptions* implement a simple form of effect typing
• Method declarations state which exceptions a method can raise
• Programmer must catch and handle any exceptions they haven’t declared they can raise
• Not much used in modern code – type system too inflexible
Effects in Koka

• Koka is a new language from Microsoft Research
• Uses effect tracking to track totality, partiality, exceptions, I/O, state and even user-defined effects
• Good playground to understand how monadic effects could look like in a practical language
• See: https://www.rise4fun.com/koka/tutorial
Questions

For the monadic I/O language:

1. State the weakening, exchange, and substitution lemmas
2. Define machine configurations and configuration typing
3. State the type safety property
