

Prefetching

Advanced Topics in Computer Architecture

Timothy Jones

Caching

- We're all familiar with caching
- Caches store data close to the core
- Caches take advantage of locality
 - Spatial locality
 - Temporal locality

Cache performance

- Cache hit and miss rates give an indication of cache performance
 - But they fail to capture the impact of the cache on the overall system
- We therefore prefer to incorporate timing into the cache performance
 - For example, including the time take to access the cache
 - And the time taken to service a miss
- This can give us a value for the average memory access time (AMAT)

Characterising cache performance

- From the CPU's point of view, we want to reduce the average memory access time (AMAT)
 - This is the average time it takes to load data
 - Including a cache in the system should lead to reducing AMAT, otherwise it is doing more harm than good!

$$\text{AMAT} = \text{Cache hit time} + \text{Cache miss rate} * \text{Cache miss penalty}$$

Improving cache performance

$$\text{AMAT} = \text{Cache hit time} + \text{Cache miss rate} * \text{Cache miss penalty}$$

- Let's consider the equation further to see how to reduce AMAT
- We can't improve the cache hit time without reducing cache size
- The cache miss penalty depends on where else the data is
 - I.e. whether it is in other caches or main memory
 - The AMAT of that cache dictates this!
- We have the most control over the cache miss rate
 - We can classify cache misses into four categories
 - Compulsory, capacity, conflict & coherence

Reducing cache misses

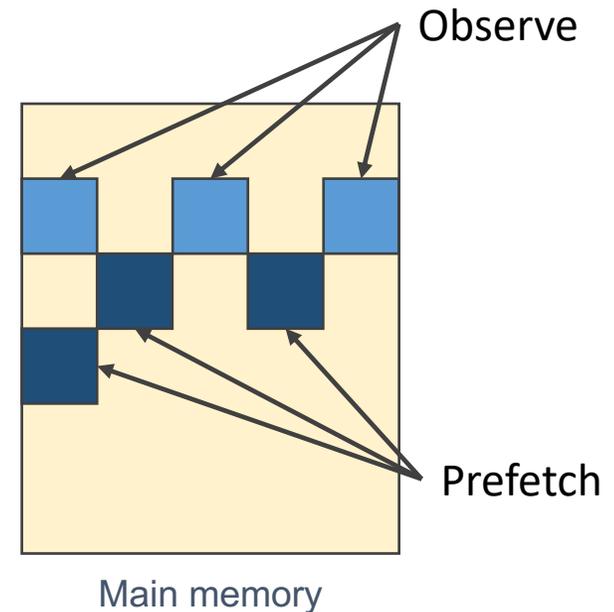

- We can reduce the number of misses in some of these classes directly
- For example, conflict misses
 - These can be reduced by increasing the size of each set
- Or capacity misses
 - These could be reduced by increasing the size of the cache
- However, we're going to focus here on schemes to improve all misses
 - All schemes employ some notion of *prefetching*

Prefetching

- This is a technique to bring data into the cache before it is needed
- The idea is to make a prediction about what data the program will use in the near future
 - Then load that data into the cache so that it arrives *before* required
- Prefetching can be performed in hardware or software
 - Processors often provide special instructions to do this in software
- We're going to look at a variety of hardware techniques

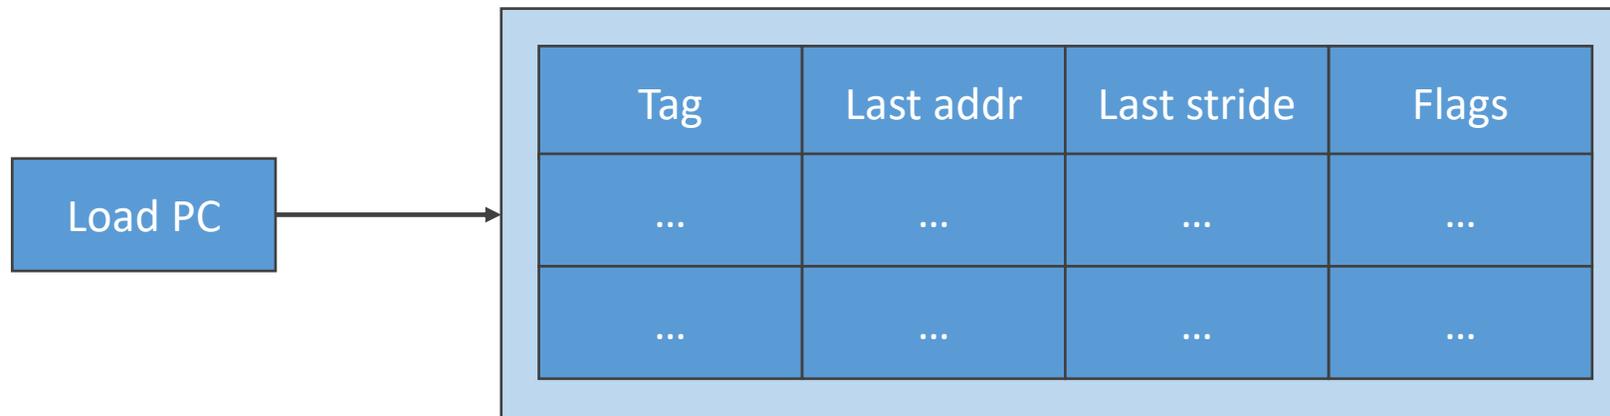

A simple prefetcher

- Next-line is a simple prefetcher
 - Does what it says on the tin!
- Stride prefetchers are also relatively simple
- The prefetcher identifies simple patterns in the accesses made
 - E.g. 0x1000, 0x1100, 0x1200
- It learns this stride and prefetches based on it

Stride prefetcher

- Stride prefetchers are great for accessing dense matrices / arrays
 - They usually provide little help for pointers
- Although simple, there are complexities
 - For example, how to distinguish between multiple interleaved streams
 - What prefetch degree or depth to use (# of blocks to prefetch)
 - Whether there should be new stream buffers to avoid cache pollution

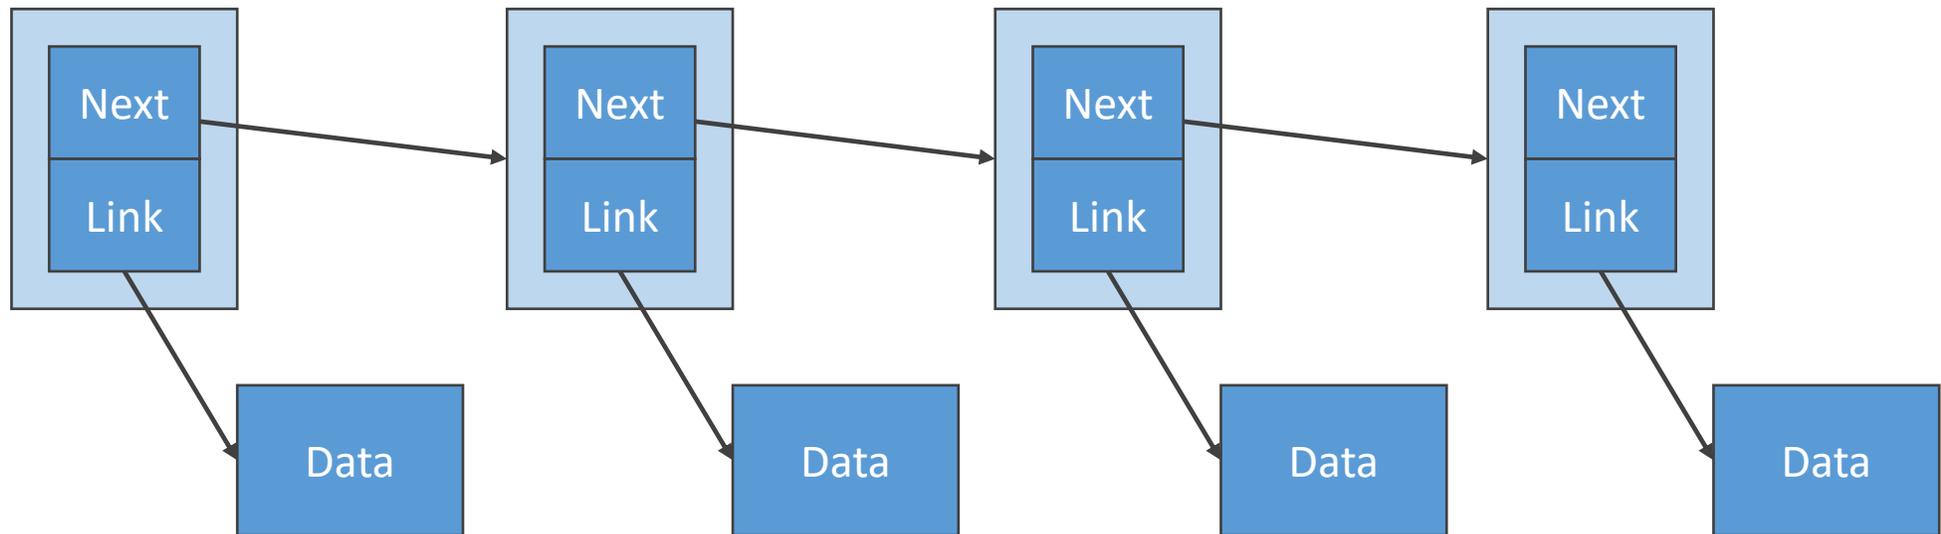

More complex prefetching

- Stride prefetchers are effective for a lot of workloads
 - Think array traversals
- But they can't pick up more complex patterns
- In particular, two types of access pattern are problematic
 - Those based on pointer chasing
 - Those that are dependent on the value of the data
- More complex prefetchers are required for these

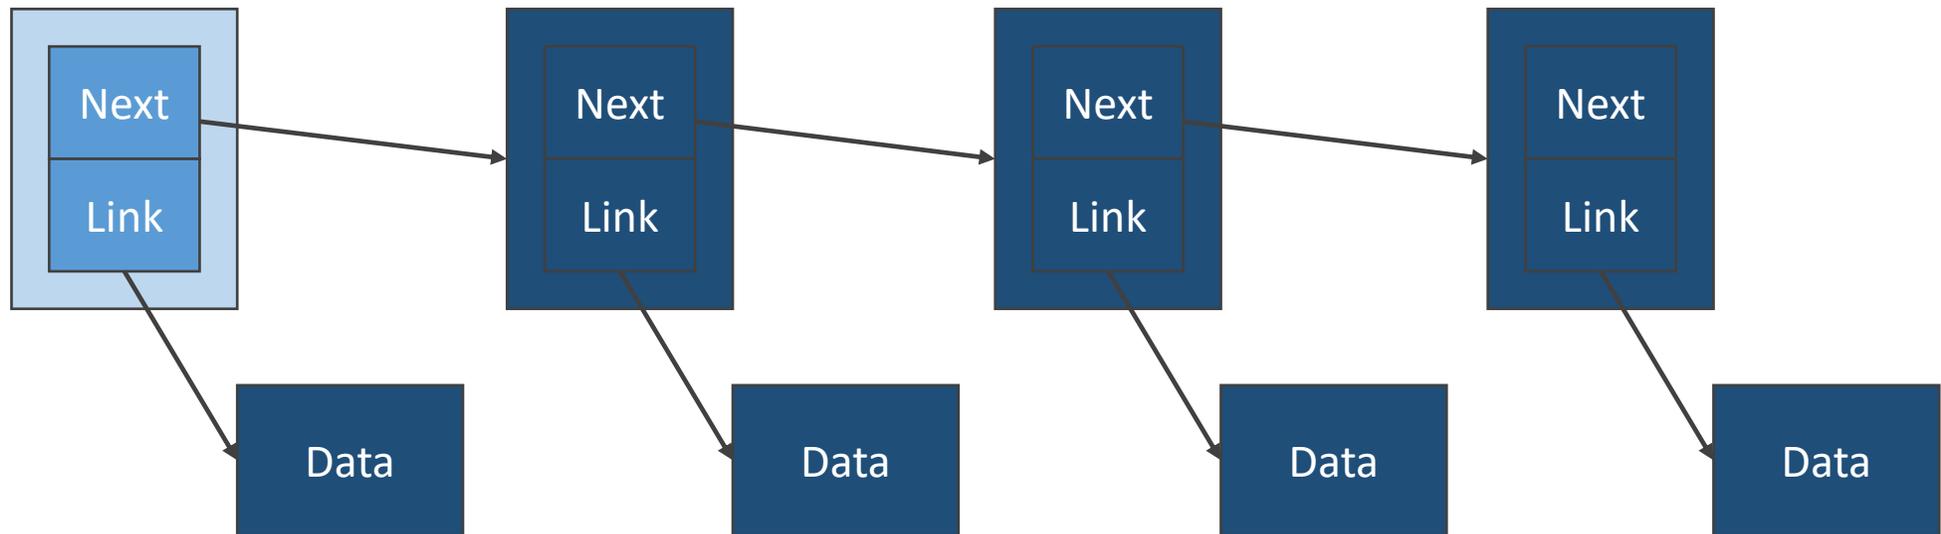

Correlation prefetching

- Irregular access patterns are not picked up well by stride prefetchers
- Correlation prefetching means correlating pairs / groups of addresses
 - When you see the first address, you can prefetch the next address

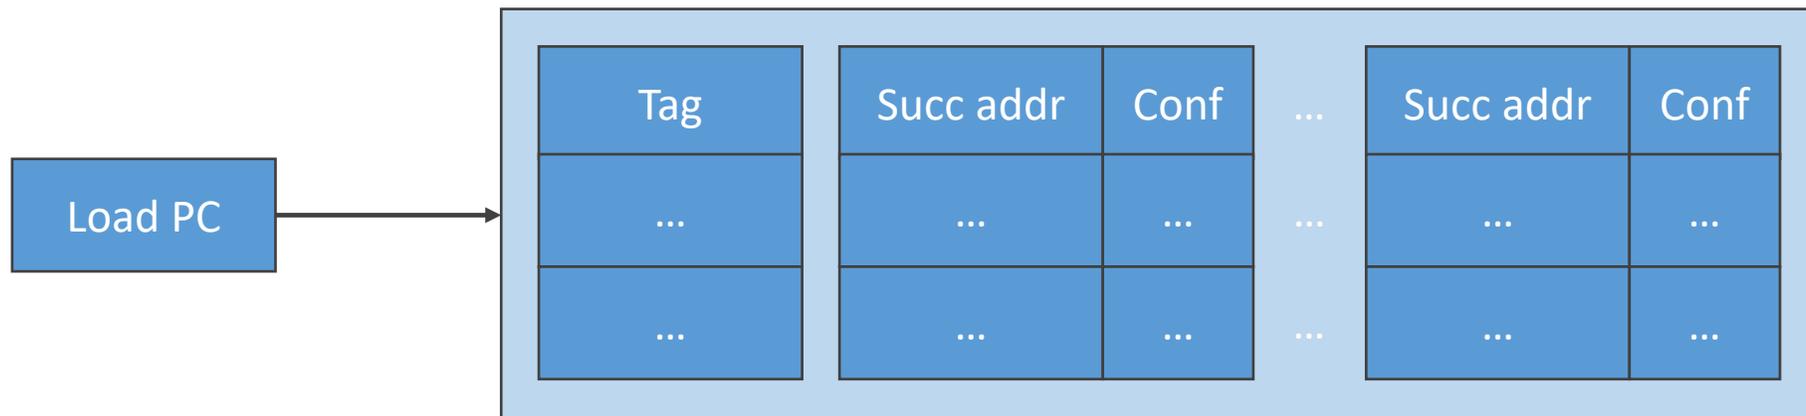

Correlation prefetching

- Irregular access patterns are not picked up well by stride prefetchers
- Correlation prefetching means correlating pairs / groups of addresses
 - When you see the first address, you can prefetch the next address

Correlation prefetching

- These work by exploiting temporal correlation
 - Essentially a hardware lookup table mapping one address to another
- They have their downsides too though
 - Must have seen the accesses before and require enormous state
- The Markov prefetcher is the most simple design

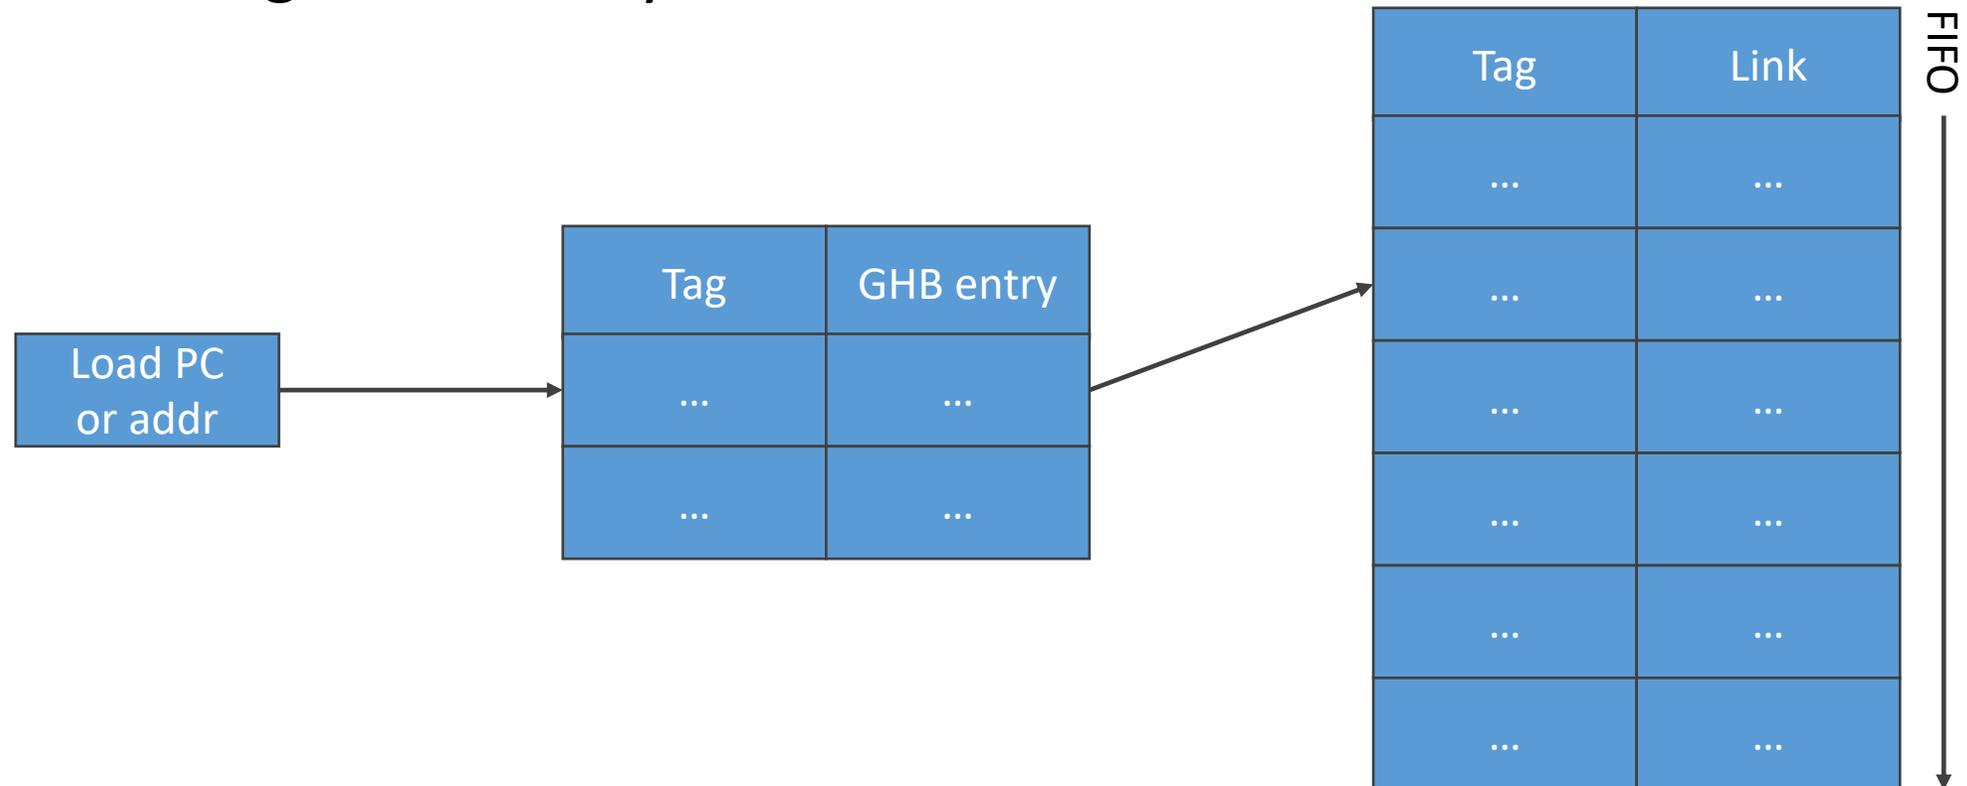

Correlation prefetching

- Markov prefetcher prefetches all successor addresses
 - LRU to manage the table entries
 - Limited depth and coverage
- Depth can be addressed by associating a stream with each load PC
 - This has its own downsides too, of course
- Depth can also be addressed by dead-block prediction
 - Based on code correlation or time keeping
- Coverage can be addressed by increasing storage
 - Perhaps by moving the correlation table into main memory

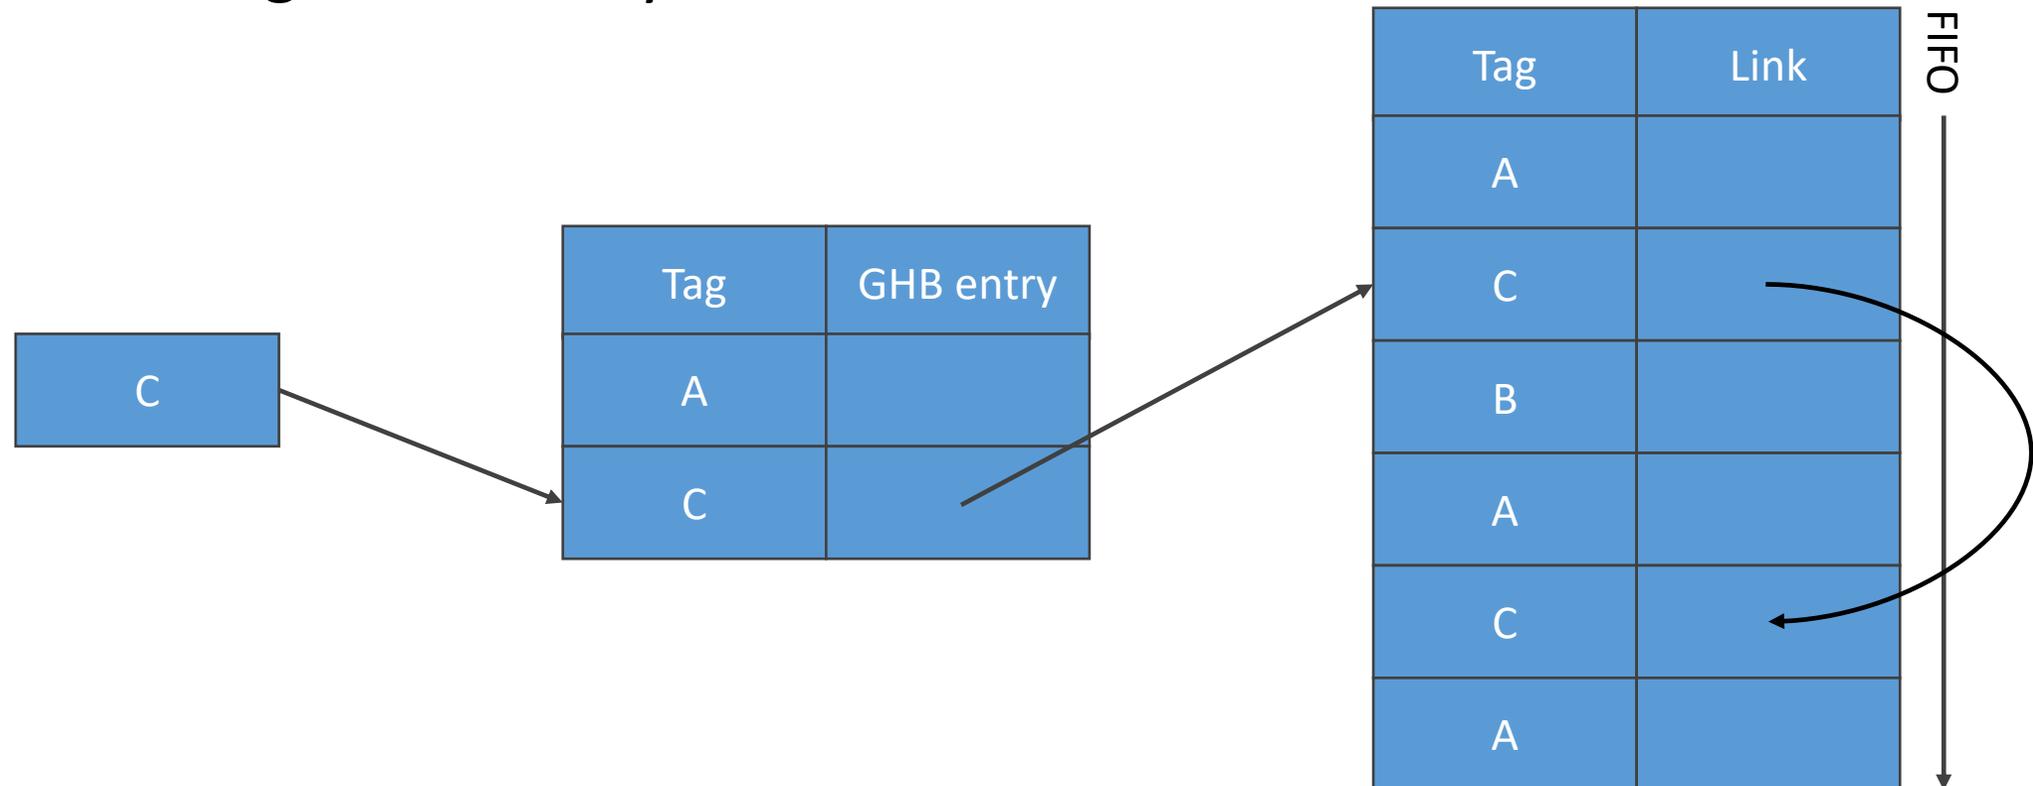

Correlation prefetching

- The Markov predictor structure limits only to fixed-length streams
- Enter the global history buffer!

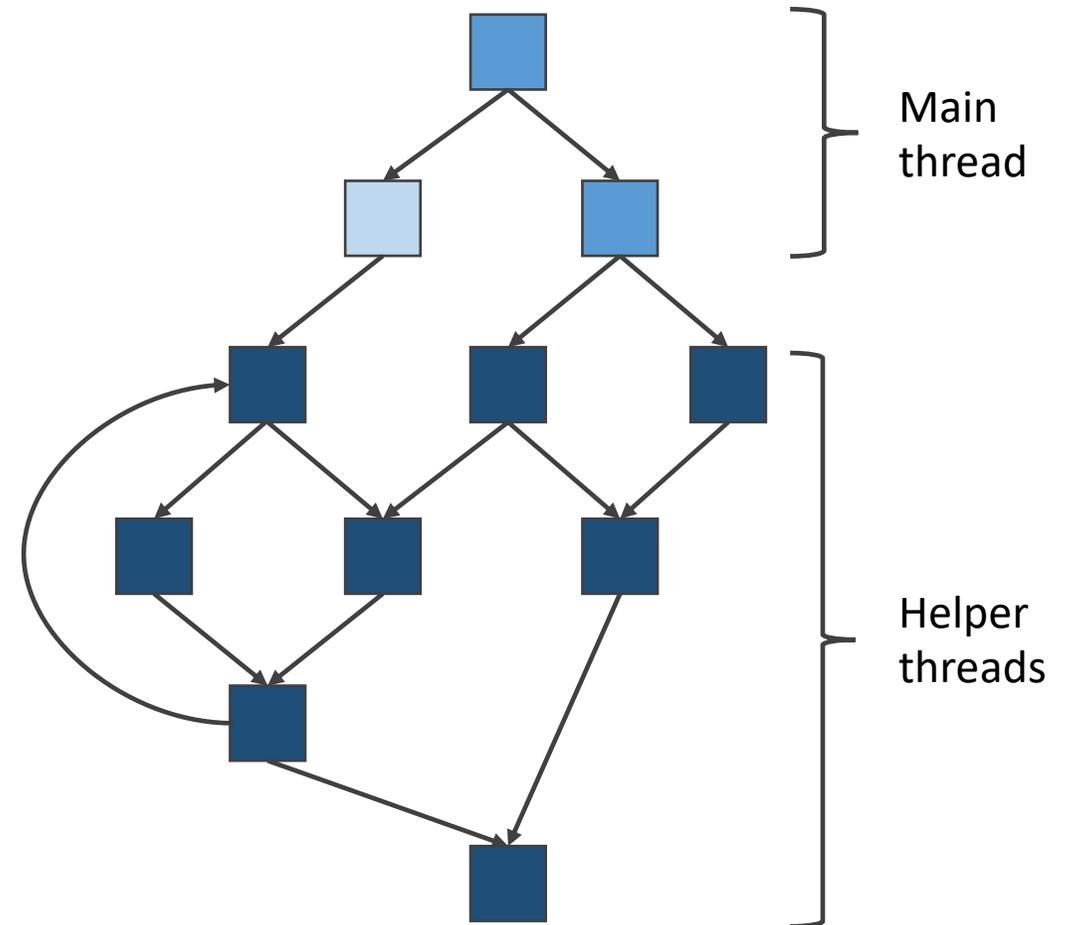

Correlation prefetching

- The Markov predictor structure limits only to fixed-length streams
- Enter the global history buffer!

Helper-thread-based prefetching

- Instead of dedicated hardware, we could use spare execution resources
 - A different SMT context
 - Continuing execution when the main thread stalls (runahead)
- Using a helper thread we can explore the future control-flow graph

Software prefetching

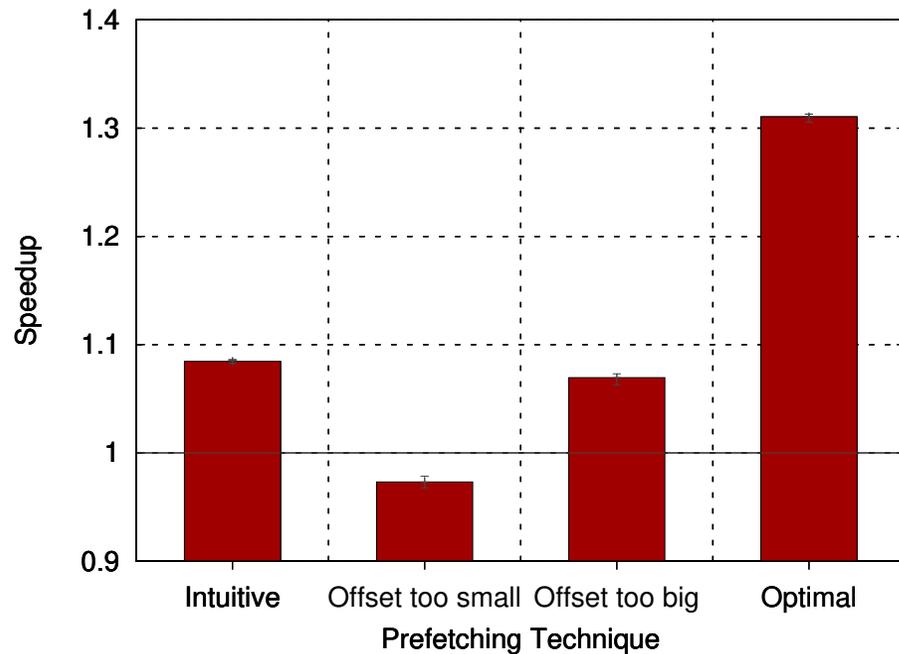

- Sometimes the programmer is better placed to help
 - Should know what's accessed next
 - Often this isn't the case!
- The architecture provides prefetching hint primitives
- When seen in code, the processor decides whether to prefetch or not

```
for (i=0; i<NUM; i++) {  
    A[B[i]]++;  
}
```

```
for (i=0; i<NUM; i++) {  
    SWPF(B[i + offset*2]);  
    SWPF(A[B[i + offset]]);  
    A[B[i]]++;  
}
```

Software prefetching

```
for (i=0; i<NUM; i++) {  
    A[B[i]]++;  
}
```

```
for (i=0; i<NUM; i++) {  
    SWPF(B[i + offset*2]);  
    SWPF(A[B[i + offset]]);  
    A[B[i]]++;  
}
```

Prefetching questions

- Whilst reading the papers for next week, here are some questions you might like to think about to judge each approach
- How do the prefetchers make their predictions?
 - Does this have a bearing on the access patterns that can be prefetched?
- What are the hardware requirements of the schemes?
 - I.e. what structures are needed to implement it and how costly are they?
- Where does the data get prefetched to?
 - Most of the time you'd like it brought into your own L1 cache
- What is the impact on other parts of the system (core, caches, etc)?
