Topic 3a: The Physical Layer

Our goals:

- Understand physical channel fundamentals
 - Physical channels can carry data in proportion to the signal and inversely in proportion to noise
 - Modulation represents Digital data in analog channels
 - Baseband vs. Broadband
 - Synchronous vs. Asynchronous

Physical Channels / The Physical Layer

these example physical channels are also known as Physical Media

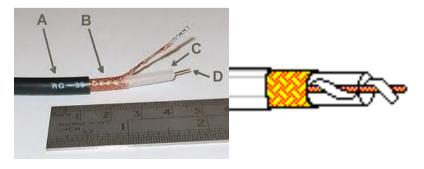

Twisted Pair (TP)

- two insulated copper wires
 - Category 3: traditional phone wires, 10 Mbps
 Ethernet
 - Category 8:
 25Gbps Ethernet
- Shielded (STP)
- Unshielded (UTP)

Coaxial cable:

- two concentric copper conductors
- bidirectional
- baseband:
 - single channel on cable
 - legacy Ethernet
- broadband:
 - multiple channels on cable
 - HFC (Hybrid Fiber Coax)

Fiber optic cable:

- high-speed operation
- point-to-point transmission
- (10' s-100' s Gbps)
- low error rate
- immune to electromagnetic noise

More Physical media: Radio

- Bidirectional and multiple access
- propagation environment effects:
 - reflection
 - obstruction by objects
 - interference

Radio link types:

- terrestrial microwave
 - e.g. 90 Mbps channels
- LAN (e.g., Wifi)
 - 11Mbps, 54 Mbps, 600 Mbps
- wide-area (e.g., cellular)
 - ✤ 5G cellular: ~ 40 Mbps 10Gbps
- satellite
 - 27-50MHz typical bandwidth
 - geosynchronous versus low altitude
 - For geosync 270 msec end-end delay to orbit

Physical Channel Characteristics - Fundamental Limits -

symbol type: generally, an analog waveform voltage, current, photo intensity etc.

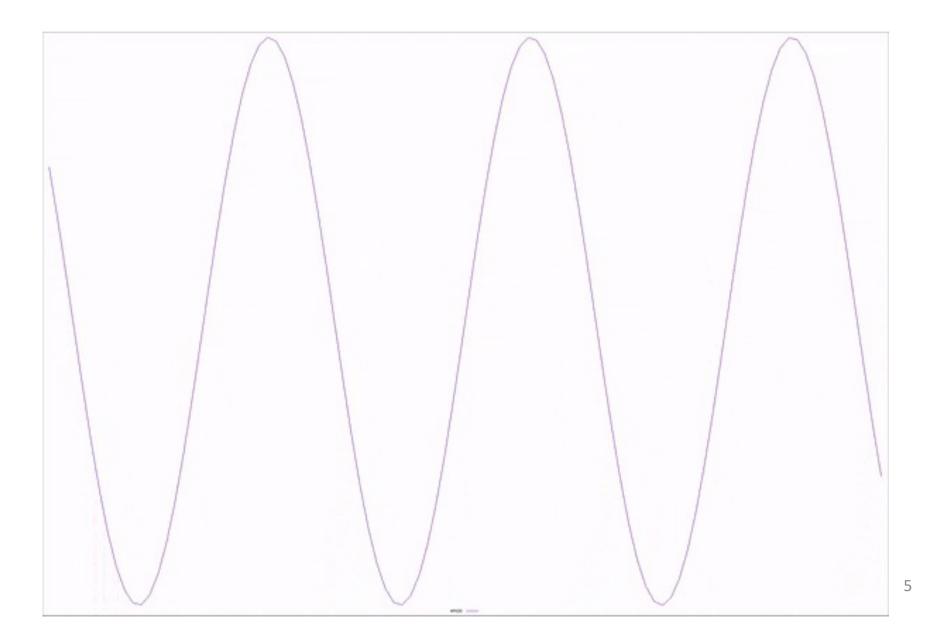

capacity: bandwidth

delay: speed of light in medium and distance travelled

fidelity: signal to noise ratio

- measure of the range of frequencies of sinusoidal signal that channel supports
- E.g., a channel that supports sinusoids from 1 MHz to 1.1 MHz has a bandwidth of 100 KHz
- "supports" in this context means "comes out the other end of the channel"
- some frequencies supported better than others
- analysing what happens to an arbitrary waveform is done by examining what happens to its component sinusoids → Fourier analysis
- bandwidth is a resource

Analog meet Digital

Analog meet Digital

Square waves have high frequency components in them

Channels attenuate frequencies irregularly: changing the shape of the signal

Receiver signal is related to the transmitted signal + noise

Noise may be systematic or random

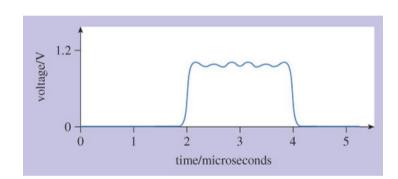

Systematic noise from interfering equipment can in principle be eliminated (not always convenient)

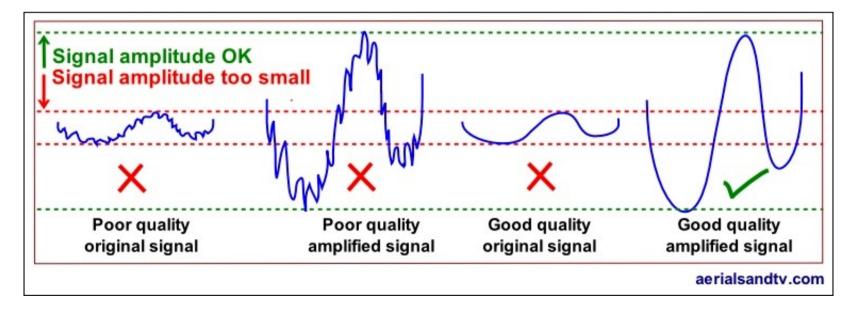

Random noise caused by thermal vibration (thermal noise)

"White" noise is evenly distributed across frequencies signal to noise ratio S/N more distance more noise

Noise: Enemy of Communications

Attenuation, External Noise, Systematic, non-systematic, digitization, interference, reflection,

Bandwidth vs Signal to Noise

what's better: high bandwidth or low signal to noise?

 channels subject to white noise have information capacity C measured in bits per second, of a channel

$$C = Blog_2(1 + S/N)$$

B is the bandwidth of the channel S/N is the ratio of received signal power to received noise power.

- channels with no noise have information capacity determined only by bandwidth
- channels with any signal have nonzero information capacity
- channels with signal to noise ratio of unity have an information capacity in bits per second equal to its bandwidth in hertz
- (This is actually NOT the definition of information capacity; it is derived from the definition)

(Digital) Channels

- Physical layer provides a channel
- Fixed rate for now
- Symbols are discrete values sent on the channel at fixed rate
- Symbols need not be binary
- Fidelity of the channel usually measured as a bit error rate the probability that a bit sent as a 1 was interpreted as a 0 by the receiver or vice versa.

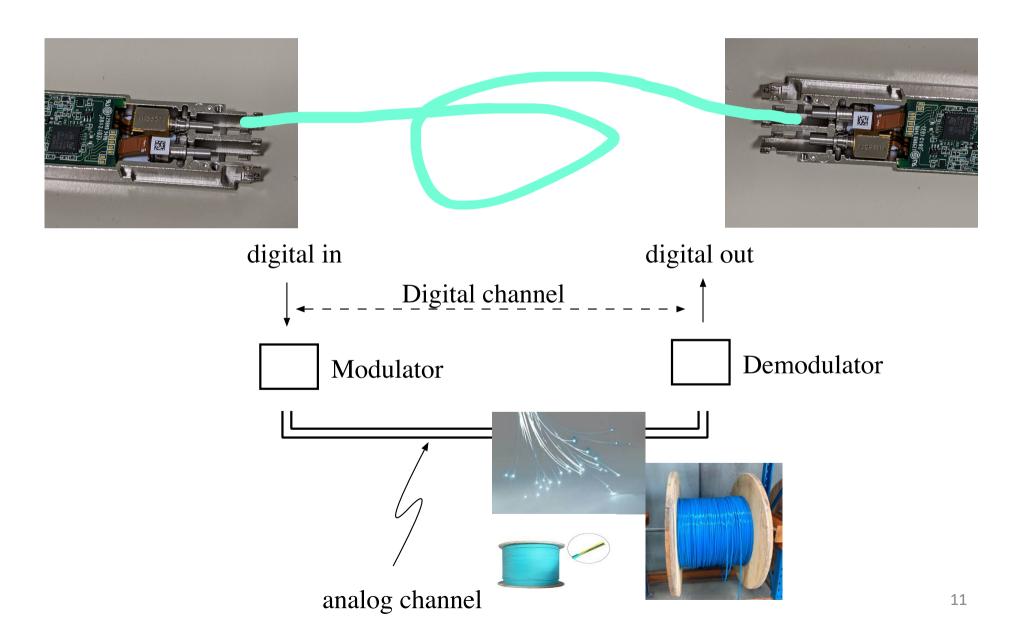

- Baud rate is the rate at which symbols can be transmitted
- Data rate (or bit rate) is the equivalent number of binary digits which can be sent
- E.g., if symbols represent with rate R then the data rate is 2 × R.

Modulation

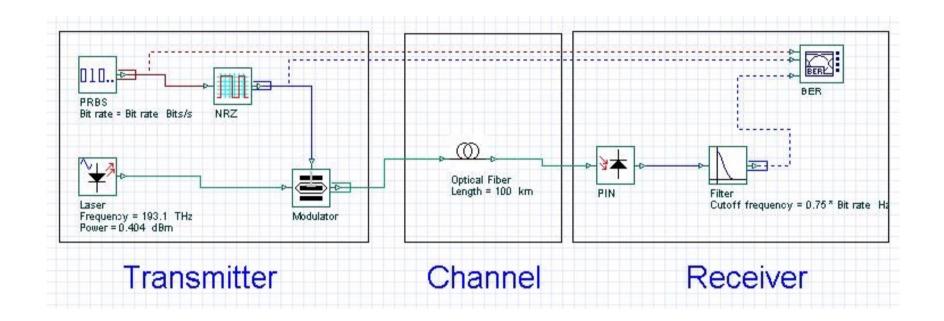

Two definitions:

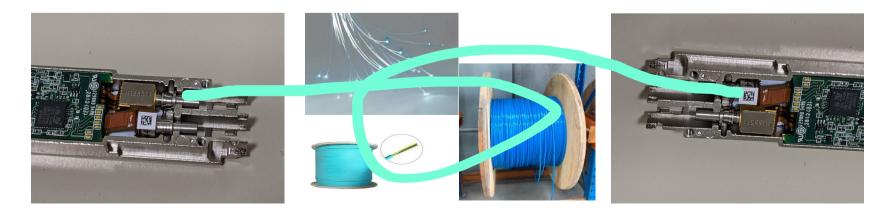

- Transform an information signal into a signal more appropriate for transmission on a physical medium
- The systematic alteration of a carrier waveform by an information signal

In general, we mean the first here (which encompasses the second).

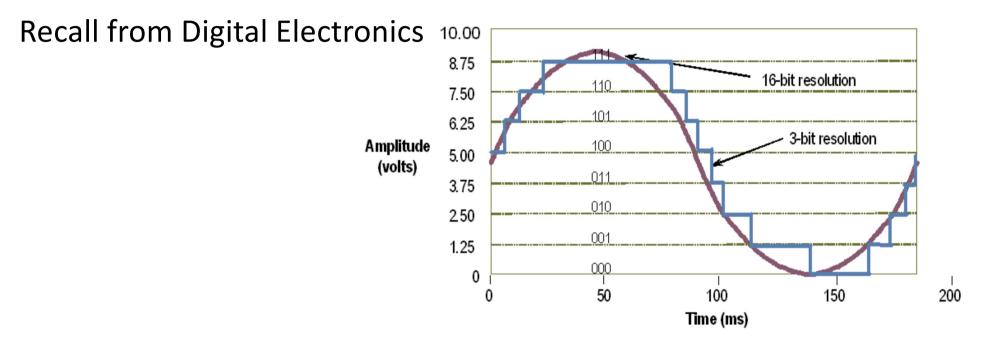

Communications

Analog/Digital Digital/Analog

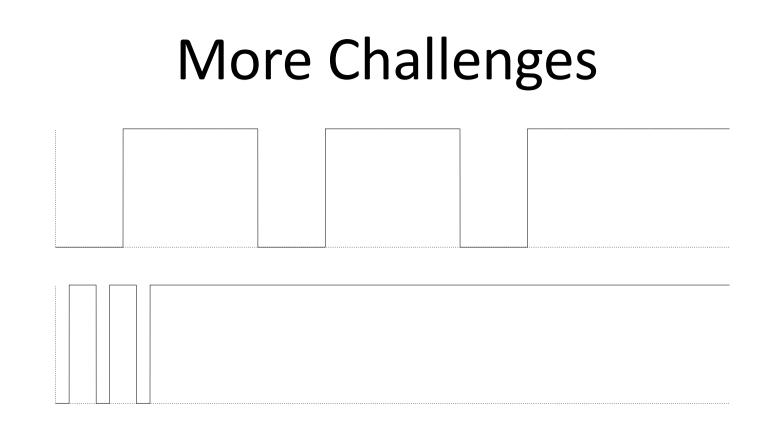

Conversion errors can occur in both directions

e.g.

Noise leads to incorrect digitization

Insufficient digitization resolution leads to information loss

Where are the bits?

WHEN are the bits?

Bit boundaries can be asynchronous or synchronous

Asynchronous versus Synchronous

- Transmission is sporadic, divided into frames
- Receiver and transmitter have oscillators which are close in frequency producing tx clocks and rx clock
- Receiver synchronises the phase of the rx clock with the tx clock by looking at one or more bit transitions
- RX clock drifts with respect to the tx clock but stays within a fraction of a bit of tx clock throughout the duration of a frame
- Transmission time is limited by accuracy of oscillators

- Transmission is continuous
- Receiver continually adjusts its frequency to track clock from incoming signal
- Requires bit transitions to inform clock
- Phase locked loop: rx clock predicts when incoming clock will change and corrects slightly when wrong.

Asynchronous versus Synchronous

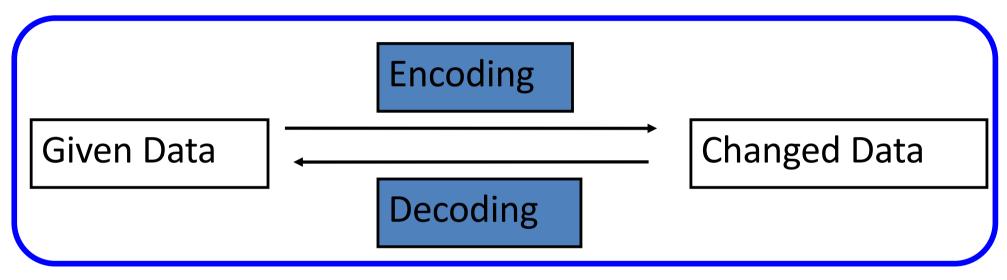

- Transmission is sporadic, divided into frames
- Receiver and transmitter have oscillators which are close in frequency producing tx clocks and rx clock
- Receiver synchronises the phase of the rx clock with the tx clock by looking at one or more bit transitions
- RX clock drifts with respect to the tx clock but stays within a fraction of a bit of tx clock throughout the duration of a frame
- Transmission time is limited by accuracy of oscillators

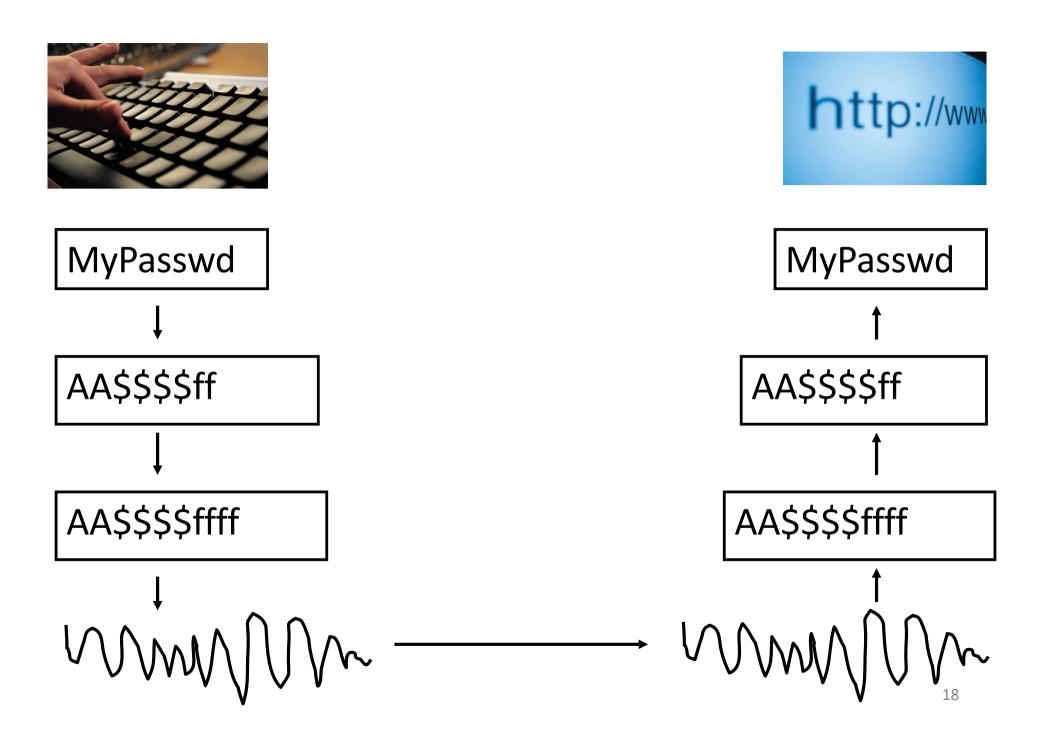

- Transmission is continuous
- Receiver continually adjusts its frequency to track clock from incoming signal
- Requires bit transitions to inform clock
- Phase locked loop: rx clock predicts when incoming clock will change and corrects slightly when wrong.

Bit transitions are critical

Coding – a channel function

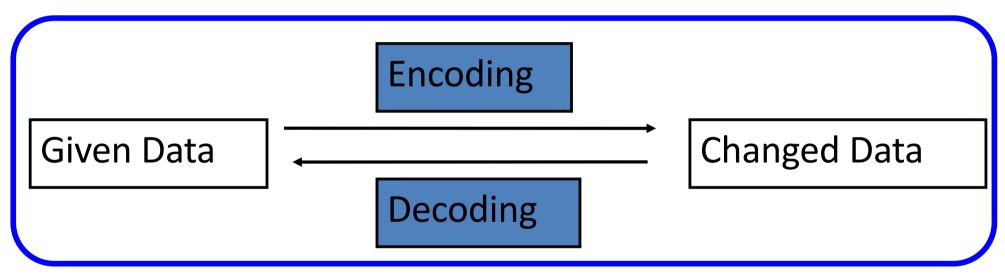

Change the representation of data.

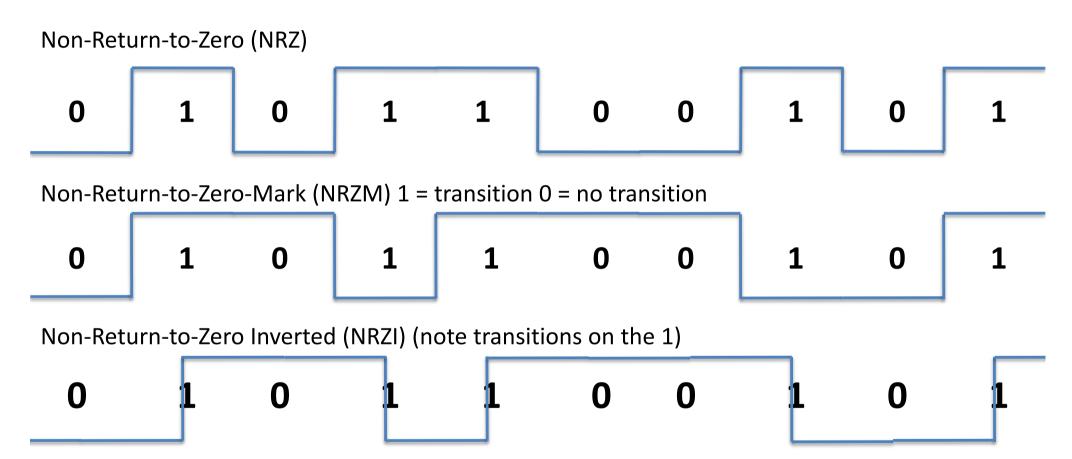

Coding

Change the representation of data.

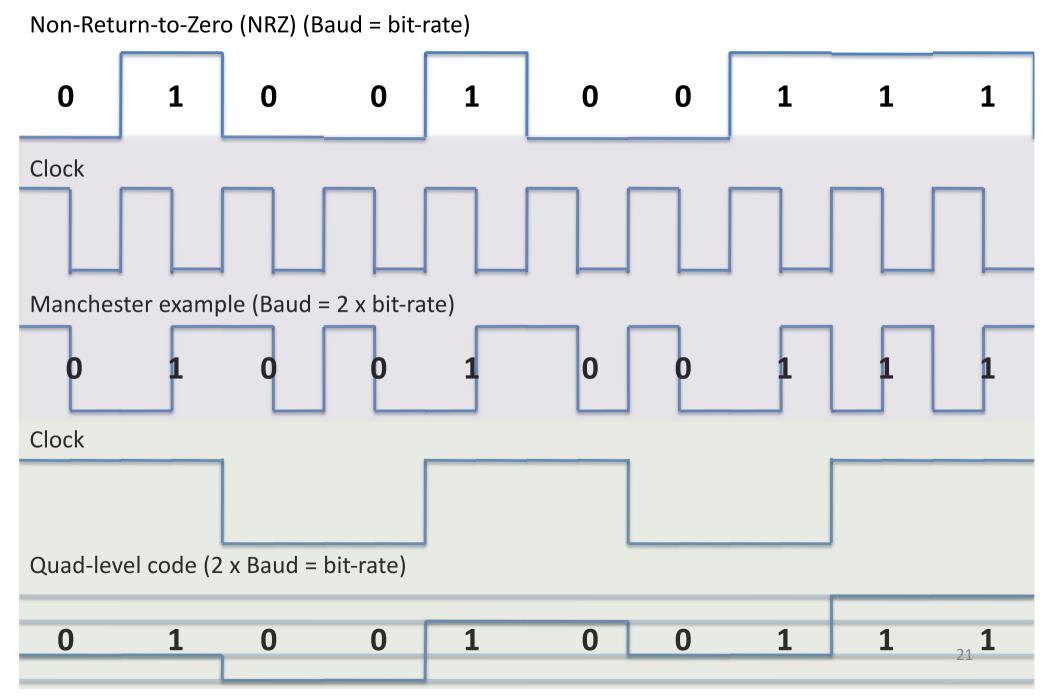

- 1. Encryption: MyPasswd <-> AA\$\$\$ff
- 2. Error Detection: AA\$\$\$ff <-> AA\$\$\$ffff
- **3.** Compression: AA\$\$\$fffff <-> A2\$4f4
- 4. Analog: A2\$4f4 <-> VVVVVVVVV

Line Coding Examples where Baud=bit-rate

Line Coding Examples

Line Coding – Block Code example

Data to send

0	1	0	0	1	0	0	1	1	1
Line-(Wii	re) represe	entation							
0	1	0	1	0	1	0	0	1	1

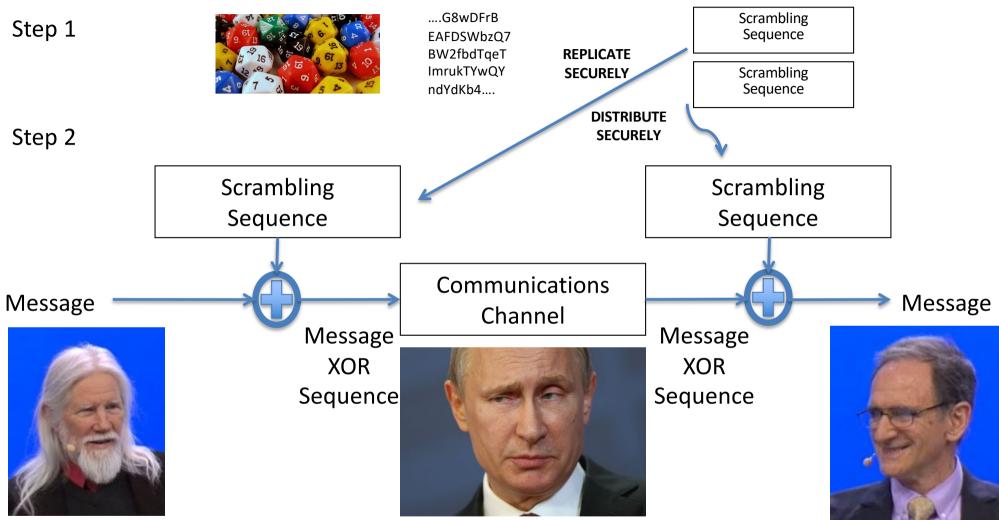

Name	4b	5b	Description		Name	4b	5b	Description
0	0000	11110	hex data 0		Q	-NONE-	00000	Quiet
1	0001	01001	hex data	1	I	-NONE-	11111	Idle
2	0010	10100	hex data	12	J	-NONE-	11000	SSD #1
3	0011	10101	hex data	3	К	-NONE-	10001	SSD #2
4	0100	01010	hex data	a 4	Т	-NONE-	01101	ESD #1
5	0101	01011	hex data	15	R	-NONE-	00111	ESD #2
6	0110	01110	hex data	6	Н	-NONE-	00100	Halt
7	0111	01111	hex data	a 7				
8		1000	10010	hex data 8				
9		1001	10011	hex data 9				
А	1010	10110	hex data	Α				
В	1011	10111	hex data	вB				
С	1100	11010	hex data	С				
D	1101	11011	hex data	a D				
E	1110	11100	hex data	ε				
F	1111	11101	hex data	a F				

Block coding transfers data with a fixed overhead: 20% less information per Baud in the case of 4B/5B

So to send data at 100Mbps; the line rate (the Baud rate) must be 125Mbps.

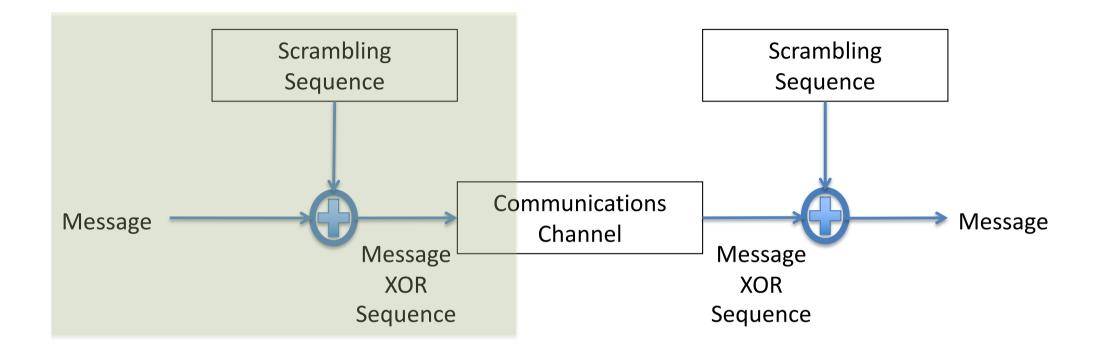

1Gbps uses an 8b/10b codec; encoding entire bytes at a time but with 25% overhead

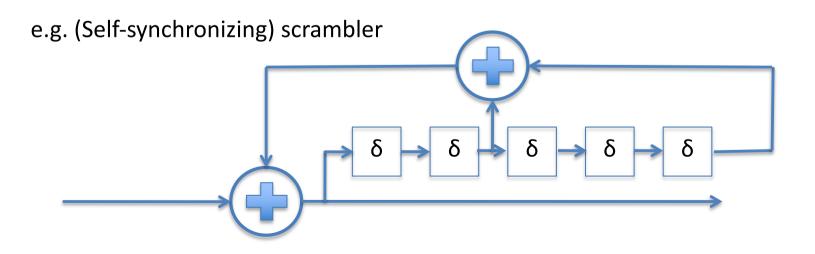

Line Coding Scrambling – with secrecy

Step 3 Don't ever reuse Scrambling sequence, ever. <<< this is quite important Whitfield Diffie

Line Coding Scrambling- no secrecy

Line Coding Examples (Hybrid)

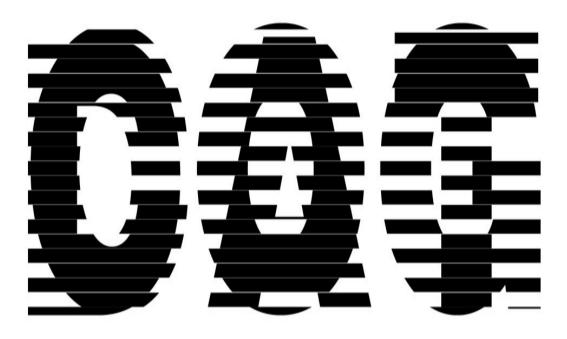

Inserted bits marking "start of frame/block/sequence"

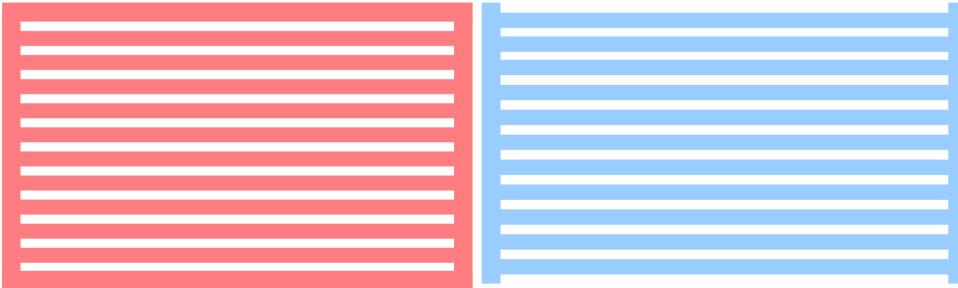

Scramble / Transmit / Unscramble

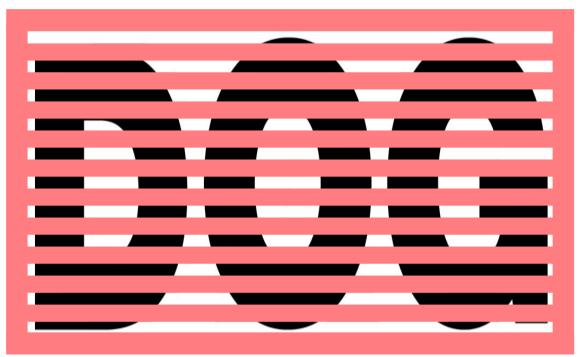

Identify (and remove) "start of frame/block/sequence" This gives you the Byte-delineations for *free*

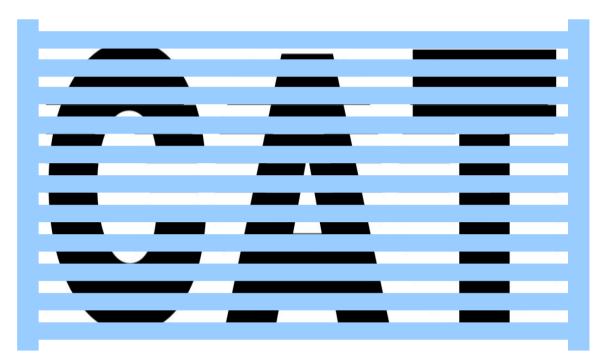

64b/66b combines a scrambler and a framer. The start of frame is a pair of bits 01 or 10: 01 means "this frame is data" 10 means "this frame contains data and control" – control could be configuration information, length of encoded data or simply "this line is idle" (no data at all)

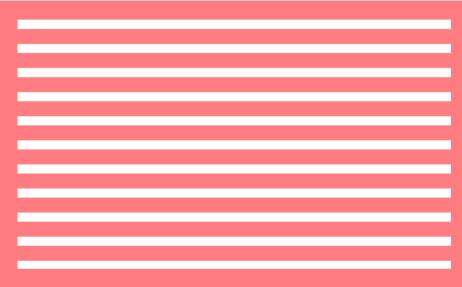

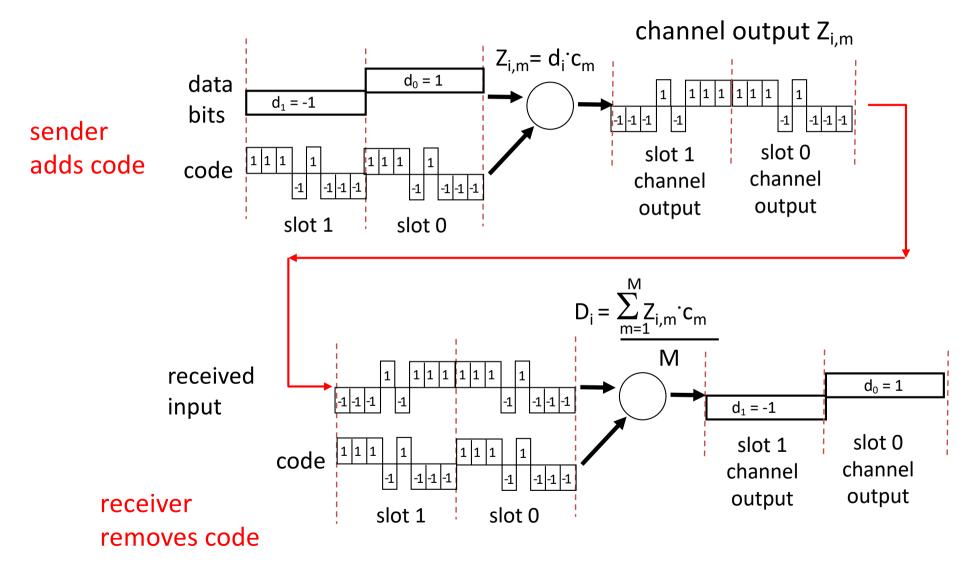

Code Division Multiple Access (CDMA) (not to be confused with CSMA!)

- used in several wireless broadcast channels (cellular, satellite, etc) standards
- unique "code" assigned to each user; i.e., code set partitioning
- all users share same frequency, but each user has own "chipping" sequence (i.e., code) to encode data
- *encoded signal* = (original data) XOR (chipping sequence)
- *decoding:* inner-product of encoded signal and chipping sequence
- allows multiple users to "coexist" and transmit simultaneously with minimal interference (if codes are "orthogonal")

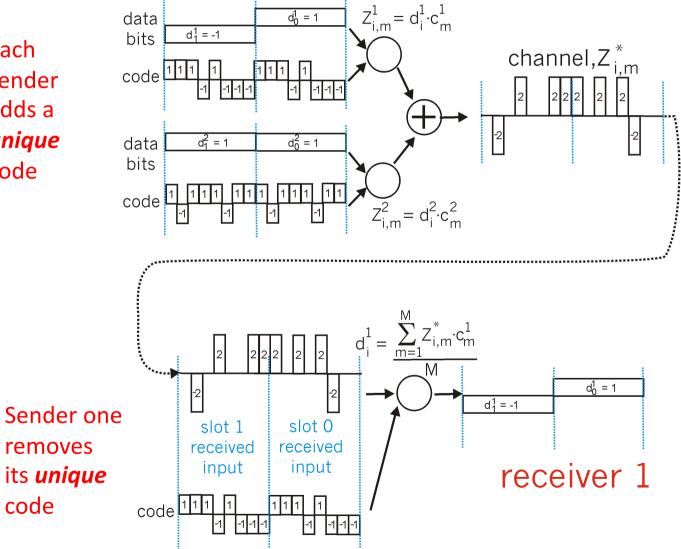

CDMA Encode/Decode

CDMA: two-sender interference

senders

Each sender adds a unique code

Coding Examples summary

- Common Wired coding
 - Block codecs: table-lookups
 - fixed overhead, inline control signals
 - Scramblers: shift registers
 - overhead free

Like earlier coding schemes and error correction/detection; you can combine these

– e.g, 10Gb/s Ethernet may use a hybrid

CDMA (Code Division Multiple Access)

- coping intelligently with competing sources
- Mobile phones

Error Detection and Correction

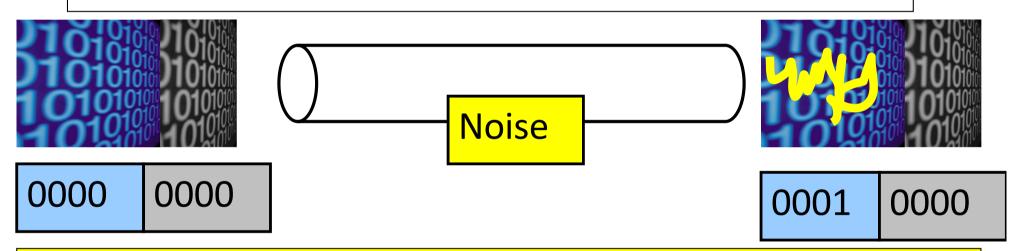

Transmission media are not perfect and cause signal impairments:

- 1. Attenuation
 - Loss of energy to overcome medium's resistance
- 2. Distortion
 - The signal changes its form or shape, caused in composite signals
- 3. Noise
 - Thermal noise, induced noise, crosstalk, impulse noise

Interference can change the shape or timing of a signal: $0 \rightarrow 1 \text{ or } 1 \rightarrow 0$

Error Detection and Correction

How to use coding to deal with errors in data communication?

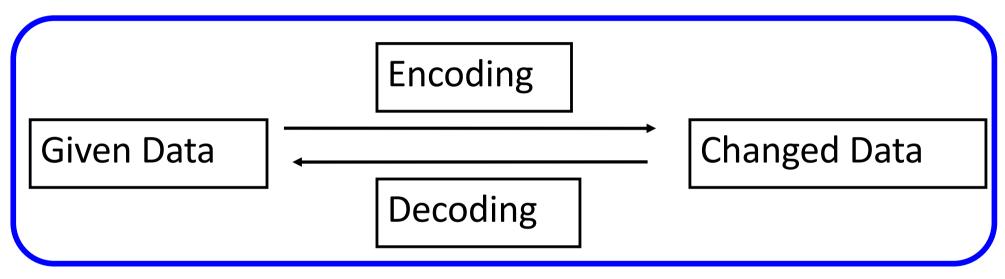

Basic Idea :

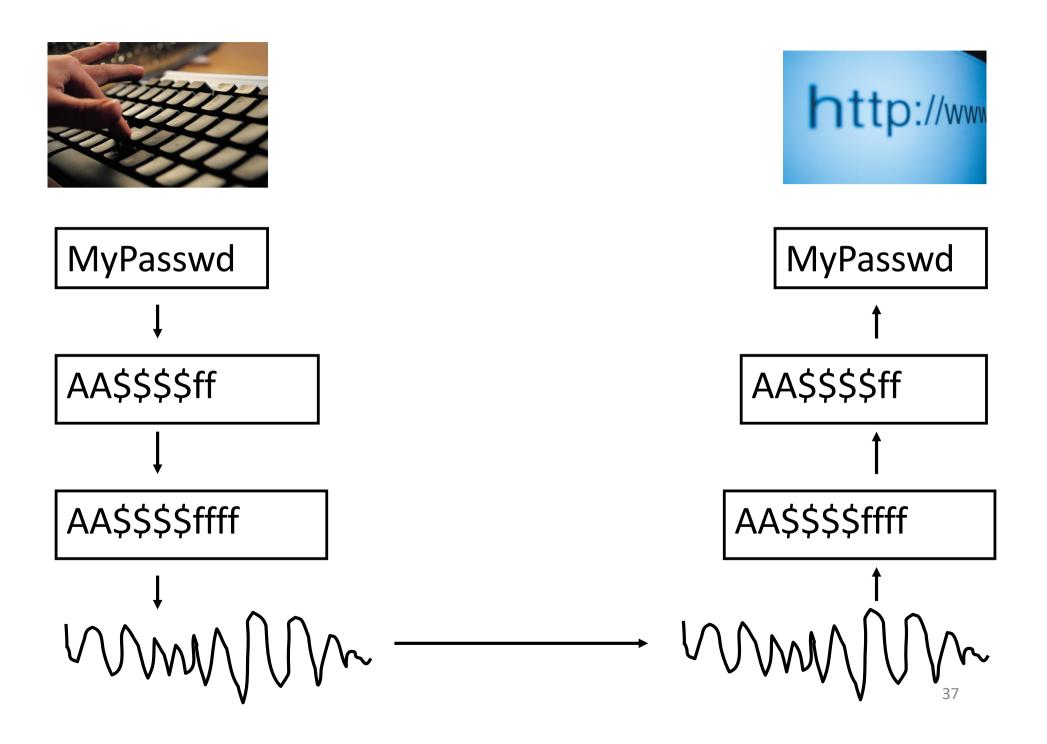

- 1. Add additional information (redundancy) to a message.
- 2. Detect an error and discard

Or, fix an error in the received message.

Coding – a channel function

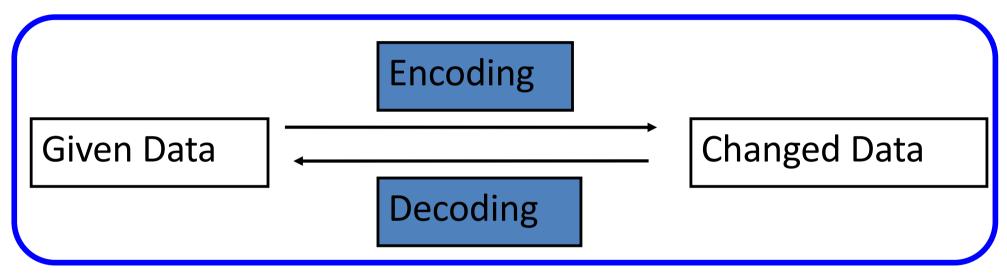

Change the representation of data.

Coding Examples

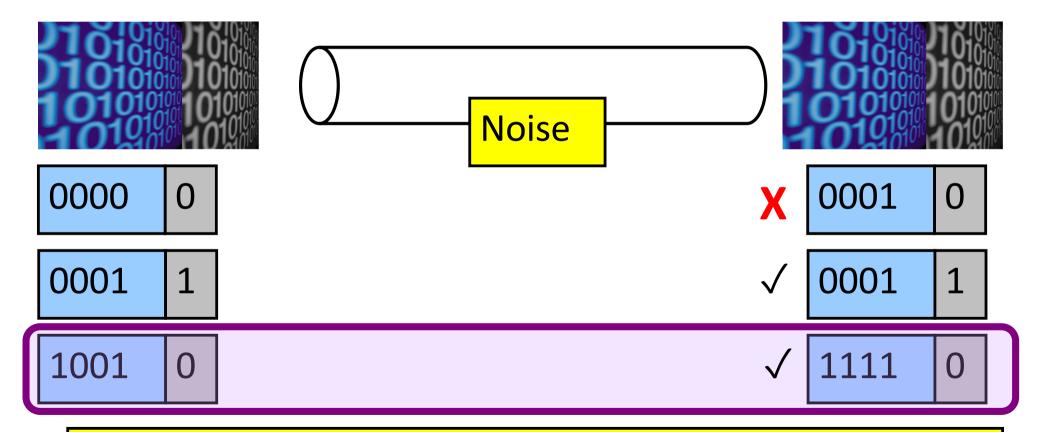

Changig the representation of data.

- 1. Encryption: MyPasswd <-> AA\$\$\$ff
- 2. Error Detection: AA\$\$\$ff <-> AA\$\$\$ffff
- **3.** Compression: AA\$\$\$fffff <-> A2\$4f4
- 4. Analog: A2\$4f4 <-> VVVVVVVVV

Error Detection Code: Parity

Add one bit, such that the number of all 1's is even.

Problem: This simple parity cannot detect two-bit errors.

Error Detection Code

Sender:

```
Y = generateCheckBit(X);
```

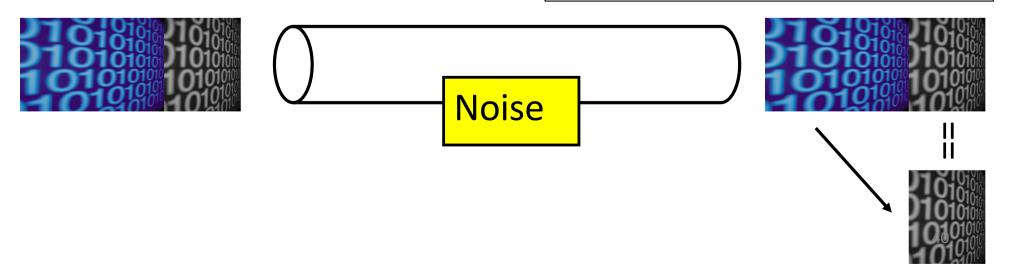

send(XY);

Receiver:

receive(X1Y1);

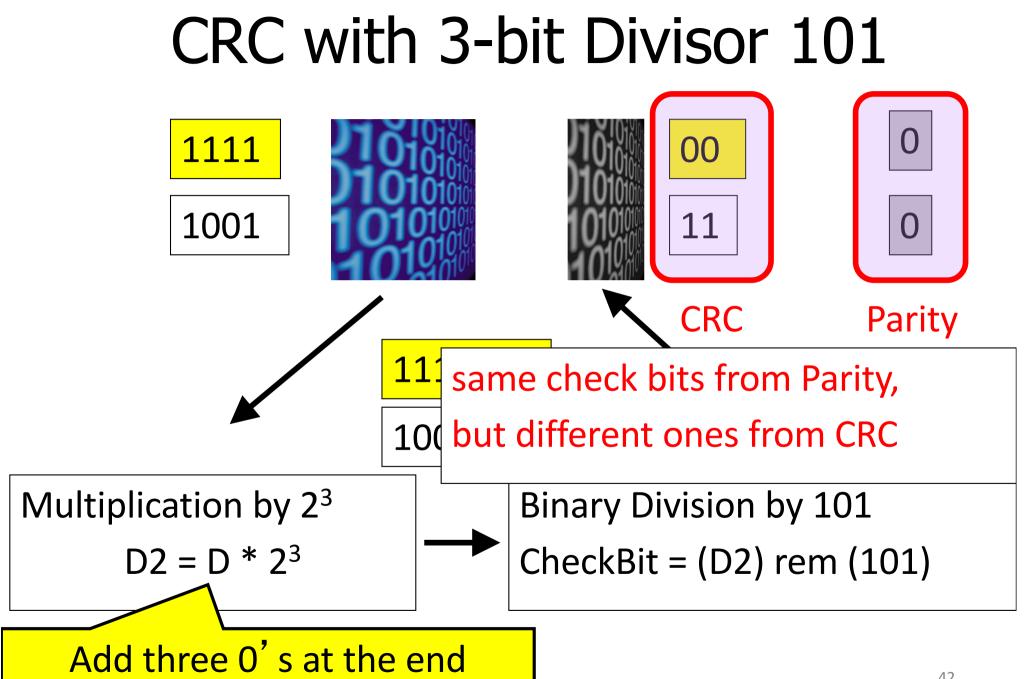

Y2=generateCheckBit(X1);

if (Y1 != Y2) ERROR;

Error Detection Code: CRC

- CRC means "Cyclic Redundancy Check".
- "A sequence of redundant bits, called CRC, is appended to the end of data so that the resulting data becomes exactly divisible by a second, predetermined binary number."
- CRC:= remainder (data ÷ predetermined divisor)
- More powerful than parity.
 - It can detect various kinds of errors, including 2-bit errors.
- More complex: <u>multiplication</u>, <u>binary division</u>.
- Parameterized by n-bit divisor P.
 - Example: 3-bit divisor 101.
 - Choosing good P is crucial.

Error Detection Code

Sender:

```
Y = generateCRC(X div P);
```

send(X);

send(Y);

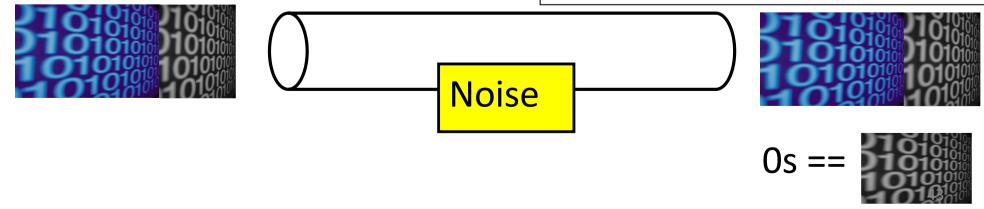

Receiver:

receive(X1);

receive(Y1);

Y2=generateCRC(X1Y1 div P);

if (Y2 != 0s) ERROR;

Transforming Error Detection to...

Sender:

```
Y = generateCheckBit(X);
```

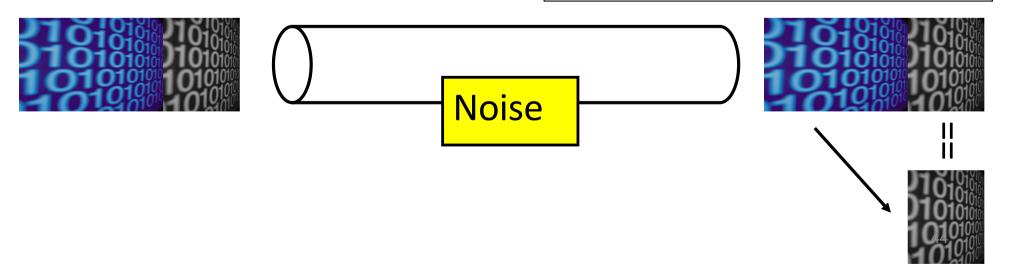

send(XY);

Receiver:

receive(X1Y1);

Y2=generateCheckBit(X1);

if (Y1 != Y2) ERROR;

Forward Error Correction (FEC)

Sender:

```
Y = generateCheckBit(X);
```

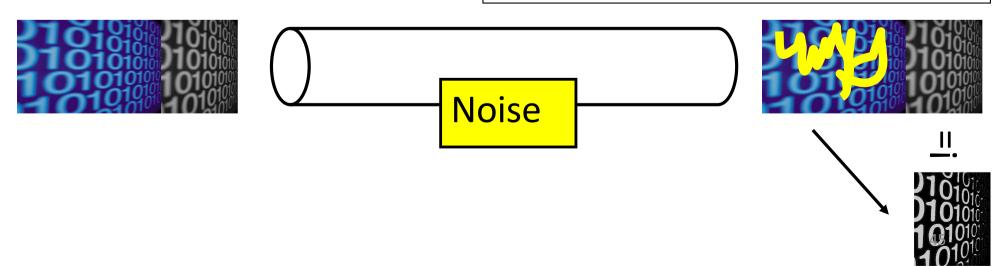

send(XY);

Receiver:

receive(X1Y1);

Y2=generateCheckBit(X1);

if (Y1 != Y2) FIXERROR(X1Y1);

Forward Error Correction (FEC)

Sender:

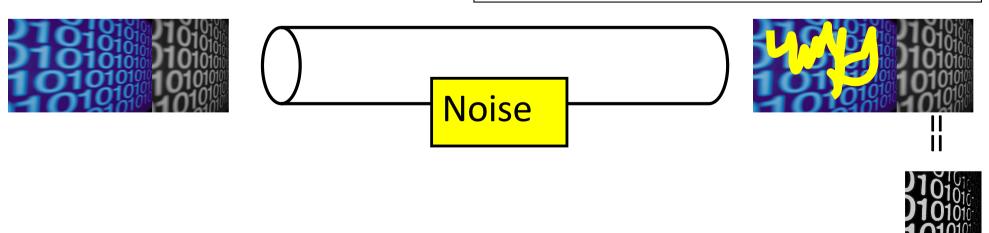

```
Y = generateCheckBit(X);
```

send(XY);

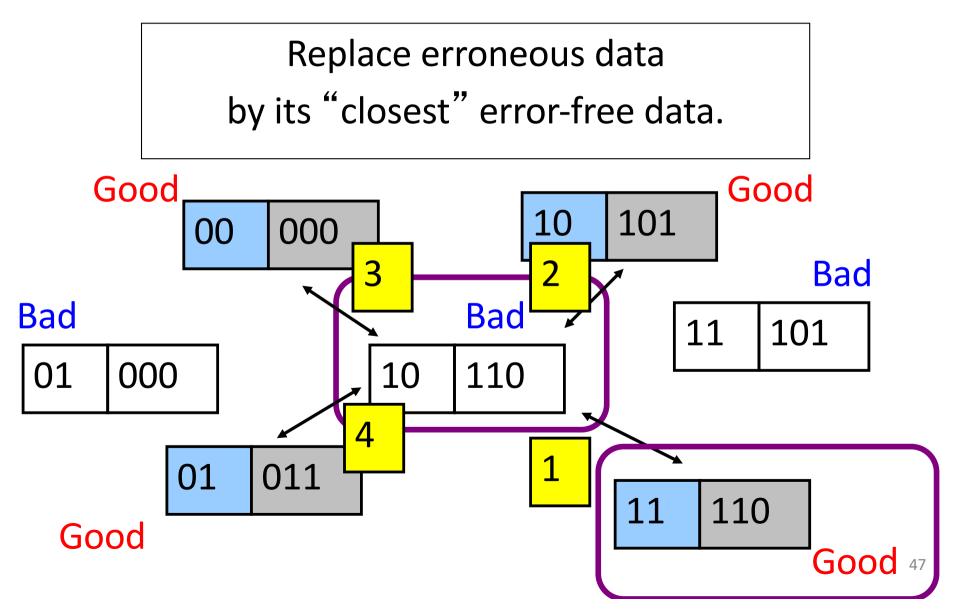

Receiver:

receive(X1Y1);
Y2=generateCheckBit(X1);

if (Y1 != Y2) FIXERROR(X1Y1);

Basic Idea of Forward Error Correction

Error Detection vs Correction

Error Correction:

- Cons: More check bits. False recovery.
- Pros: No need to re-send.

Error Detection:

- Cons: Need to re-send.
- Pros: Less check bits.

Usage:

- Correction: A lot of noise. Expensive to re-send.
- Detection: Less noise. Easy to re-send.
- Can be used together.

Topic 3b: The Data Link Layer

Our goals:

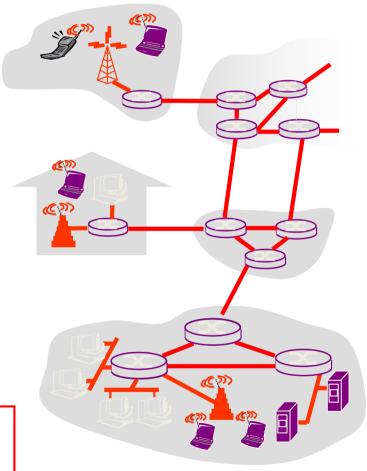

- understand principles behind data link layer services: (these are methods & mechanisms in your networking toolbox)
 - error detection, correction
 - sharing a broadcast channel: multiple access
 - link layer addressing
 - reliable data transfer, flow control
- instantiation and implementation of various link layer technologies
 - Wired Ethernet (aka 802.3)
 - Wireless Ethernet (aka 802.11 WiFi)
- Algorithms
 - Binary Exponential Back-off
 - Spanning Tree (Dijkstra)
- General knowledge
 - Random numbers are important and hard

Link Layer: Introduction

Some reminder-terminology:

- hosts and routers are nodes
- communication channels that connect adjacent nodes along communication path are links
 - wired links
 - wireless links
 - LANs
- layer-2 packet is a frame, encapsulates datagram

data-link layer has responsibility of transferring datagram from one node to adjacent node over a link

Link Layer (Channel) Services - 1/2

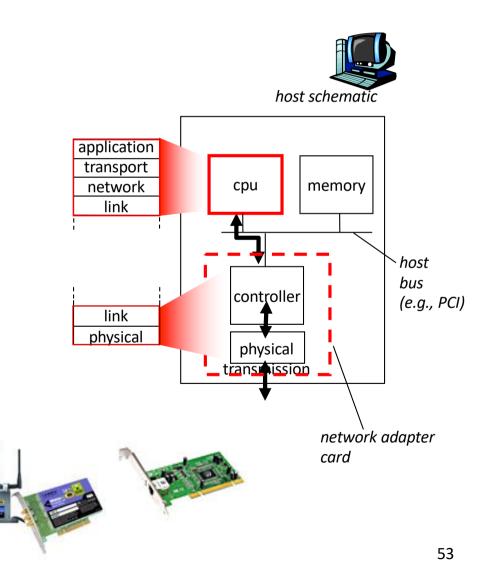

- framing, physical addressing:
 - encapsulate datagram into frame, adding header, trailer
 - channel access if shared medium
 - "MAC" addresses used in frame headers to identify source, destination
 - This is **not** an IP address!
- reliable delivery between adjacent nodes
 - we revisit this again in the Transport Topic
 - seldom used on low bit-error link (fiber, some twisted pair)
 - wireless links: high error rates

Link Layer (Channel) Services – 2/2

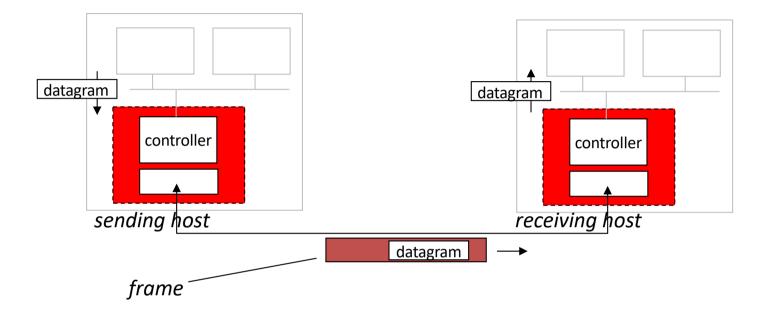

- flow control:
 - pacing between adjacent sending and receiving nodes
- error control:
 - *error detection:*
 - errors caused by signal attenuation, noise.
 - receiver detects presence of errors:
 - signals sender for retransmission or drops frame
 - error correction:
 - receiver identifies and corrects bit error(s) without resorting to retransmission
- access control: half-duplex and full-duplex
 - with half duplex, nodes at both ends of link can transmit, but not at same time

Where is the link layer implemented?

- in each and every host
- link layer implemented in "adaptor" (aka *network interface card* NIC)
 - Ethernet card, PCMCI card, 802.11 card
 - implements link, physical layer
- attaches into host's system buses
- combination of hardware, software, firmware

Adaptors Communicating

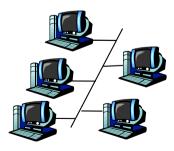

- sending side:
 - encapsulates datagram in frame
 - encodes data for the physical layer
 - adds error checking bits, provide reliability, flow control, etc.

- receiving side
 - decodes data from the physical layer
 - looks for errors, provide reliability, flow control, etc
 - extracts datagram, passes to upper layer at receiving side

Multiple Access Links and Protocols

Two types of "links":

- point-to-point
 - point-to-point link between Ethernet switch and host
- broadcast (shared wire or medium)
 - old-fashioned wired Ethernet (*here be dinosaurs* extinct)
 - upstream HFC (Hybrid Fiber-Coax the Coax may be broadcast)
 - Home plug / Powerline networking
 - 802.11 wireless LAN

shared wire (e.g., Coax cabled Ethernet)

shared RF (e.g., 802.11 WiFi)

shared RF (satellite)

humans at a cocktail party (shared air, acoustical)

Multiple Access protocols

- single shared broadcast channel
- two or more simultaneous transmissions by nodes: interference
 - collision if node receives two or more signals at the same time

multiple access protocol

- distributed algorithm that determines how nodes share channel, i.e., determine when node can transmit
- communication about channel sharing must use channel itself!
 - no out-of-band channel for coordination

Ideal Multiple Access Protocol

Broadcast channel of rate R bps

- 1. when one node wants to transmit, it can send at rate R
- 2. when *M* nodes want to transmit,

each can send at average rate R/M

- 3. fully decentralized:
 - no special node to coordinate transmissions
 - no synchronization of clocks, slots
- 4. simple

MAC Protocols: a taxonomy

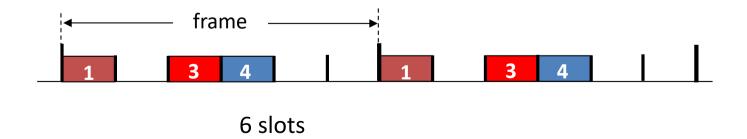

Three broad classes:

- Channel Partitioning
 - divide channel into smaller "pieces" (time slots, frequency, code)
 - allocate piece to node for exclusive use
- Random Access
 - channel not divided, allow collisions
 - "recover" from collisions
- "Taking turns"
 - nodes take turns, but nodes with more to send can take longer turns

Channel Partitioning MAC protocols: TDMA (we discussed this earlier)

TDMA: time division multiple access

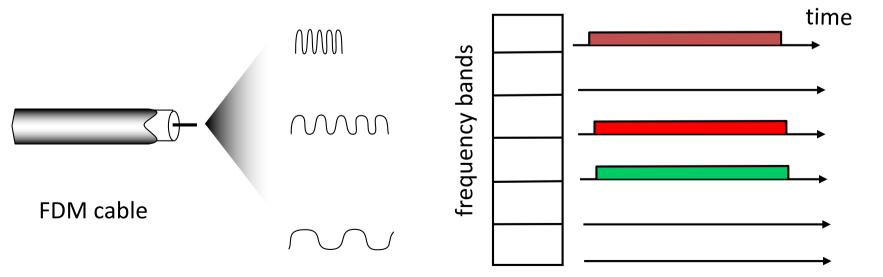

- access to channel in "rounds"
- each station gets fixed length slot (length = pkt trans time) in each round
- unused slots go idle
- example: station LAN, 1,3,4 have pkt, slots 2,5,6 idle

Channel Partitioning MAC protocols: FDMA (we discussed this earlier)

FDMA: frequency division multiple access

- channel spectrum divided into frequency bands
- each station assigned fixed frequency band
- unused transmission time in frequency bands go idle
- example: station LAN, 1,3,4 have pkt, frequency bands 2,5,6 idle

channel partitioning MAC protocols:

- share channel *efficiently* and *fairly* at high load
- inefficient at low load: delay in channel access, 1/N bandwidth allocated even if only 1 active node!

random access MAC protocols:

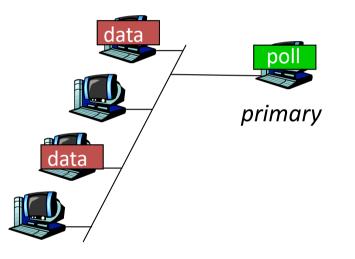

- efficient at low load: single node can fully utilize channel
- high load: collision overhead

"taking turns" protocols:

look for best of both worlds!

Polling:

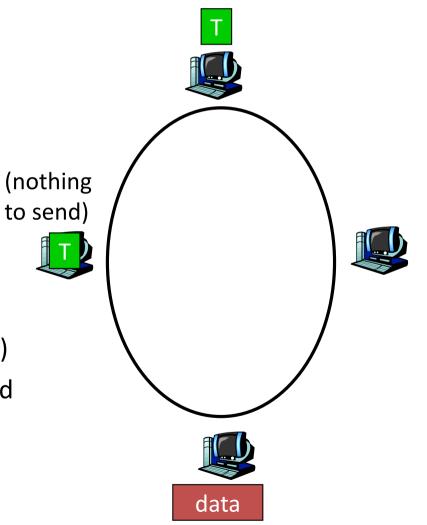

- Primary node "invites" subordinates nodes to transmit in turn
- typically used with simpler subordinate devices
- concerns:
 - polling overhead
 - latency
 - single point of failure (primary)

subordinates

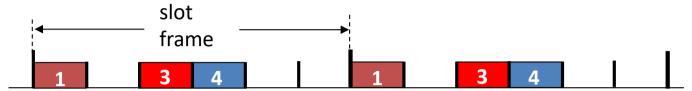

Token passing:

- control token passed from one node to next sequentially.
- token message
- concerns:
 - token overhead
 - latency
 - single point of failure (token)
- concerns fixed in part by a slotted ring (many simultaneous *tokens*)

ATM

In TDM a sender may only use a pre-allocated slot

In ATM a sender transmits labeled cells whenever necessary

ATM = Asynchronous Transfer Mode – an ugly expression think of it as ATDM – Asynchronous Time Division Multiplexing

That's a variant of **PACKET SWITCHING** to the rest of us – just like Ethernet but using fixed length slots/packets/cells

Use the media when you need it, but ATM had virtual circuits and these needed setup....

channel partitioning MAC protocols:

- share channel *efficiently* and *fairly* at high load
- inefficient at low load: delay in channel access, 1/N
 bandwidth allocated even if only 1 active node!

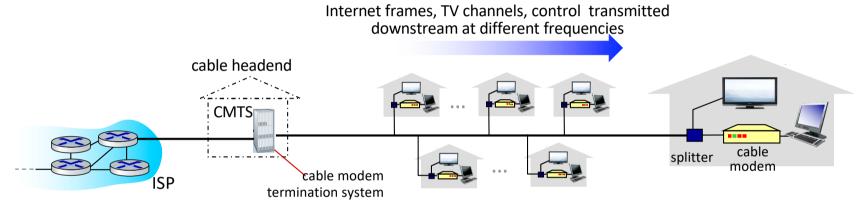

random access MAC protocols:

- efficient at low load: single node can fully utilize channel
- high load: collision overhead
- "taking turns" protocols:

look for best of both worlds!

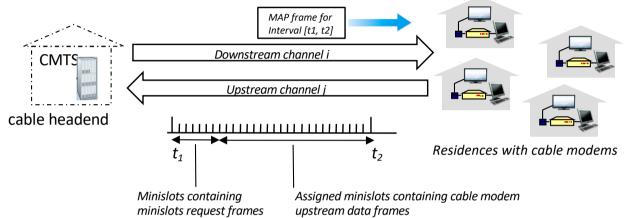

Cable access network: FDM, TDM and random access!

- multiple downstream (broadcast) FDM channels: up to 1.6 Gbps/channel
 - single CMTS transmits into channels
- multiple upstream channels (up to 1 Gbps/channel)
 - multiple access: all users contend (random access) for certain upstream channel time slots; others assigned TDM

DOCSIS: data over cable service interface specification

- FDM over upstream, downstream frequency channels
- TDM upstream: some slots assigned, some have contention
 - downstream MAP frame: assigns upstream slots
 - request for upstream slots (and data) transmitted random access (binary backoff) in selected slots

Random Access MAC Protocols

- When node has packet to send
 - Transmit at full channel data rate
 - No *a priori* coordination among nodes
- Two or more transmitting nodes \Rightarrow collision
 - Data lost
- Random access MAC protocol specifies:
 - How to detect collisions
 - How to recover from collisions
- Examples
 - ALOHA and Slotted ALOHA
 - CSMA, CSMA/CD, CSMA/CA (wireless)

Key Ideas of Random Access

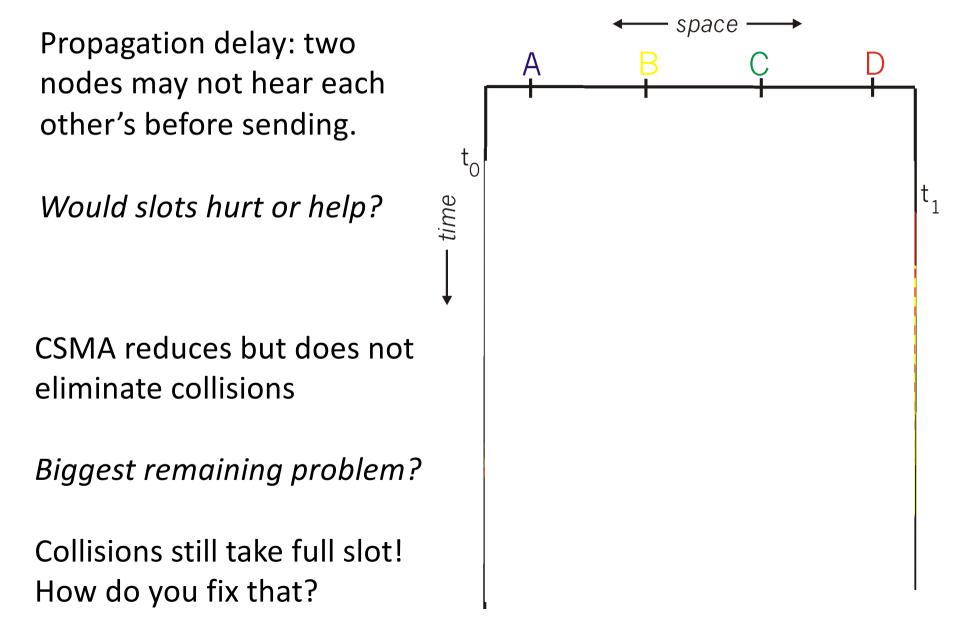

- Carrier sense
 - Listen before speaking, and don't interrupt
 - Checking if someone else is already sending data
 - and waiting till the other node is done
- Collision detection
 - If someone else starts talking at the same time, stop
 - Realizing when two nodes are transmitting at once
 - ...by detecting that the data on the wire is garbled
- Randomness
 - Don't start talking again right away
 - Waiting for a random time before trying again

CSMA (Carrier Sense Multiple Access)

- CSMA: listen before transmit

 If channel sensed idle: transmit entire frame
 If channel sensed busy, defer transmission
- Human analogy: don't interrupt others!
- Does this eliminate all collisions?
 No, because of nonzero propagation delay

CSMA Collisions

CSMA/CD (Collision Detection)

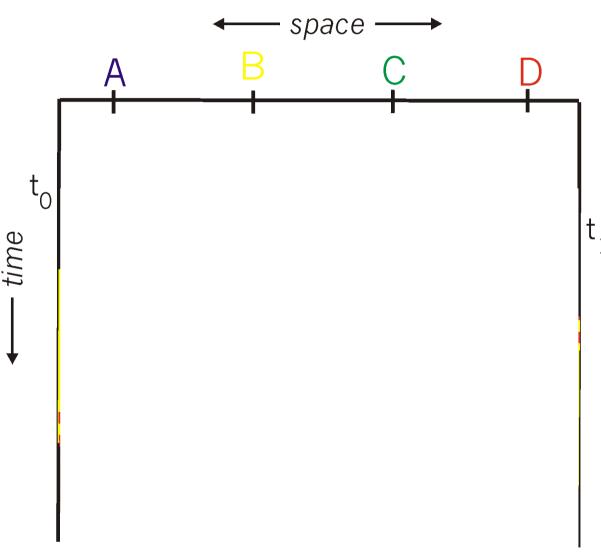

- CSMA/CD: carrier sensing, deferral as in CSMA
 - Collisions detected within short time
 - Colliding transmissions aborted, reducing wastage
- Collision detection easy in wired LANs:
 - Compare transmitted, received signals
- Collision detection difficult in wireless LANs:
 - Reception shut off while transmitting (well, perhaps not)
 - Not perfect broadcast (limited range) so collisions local
 - Leads to use of *collision avoidance* instead (later)

CSMA/CD Collision Detection

B and D can tell that collision occurred.

Note: for this to work, need restrictions on minimum frame size and maximum distance. Why?

Limits on CSMA/CD Network Length latency d

- Latency depends on physical length of link
 - Time to propagate a packet from one end to the other
- Suppose A sends a packet at time **t**
 - And B sees an idle line at a time just before t+d
 - ... so B happily starts transmitting a packet
- *B* detects a collision, and sends jamming signal
 - But A can't see collision until t+2d

Performance of CSMA/CD

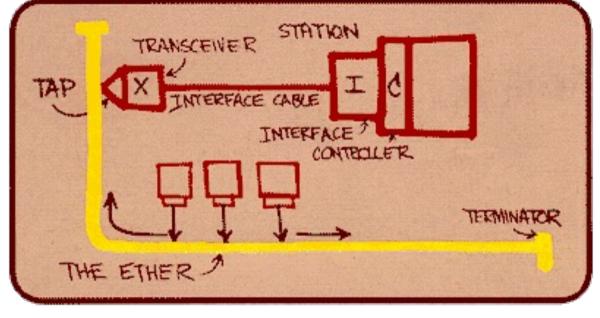

- Time wasted in collisions
 - Proportional to distance d
- Time spend transmitting a packet
 - Packet length p divided by bandwidth b
- Rough estimate for efficiency (K some constant)

$$E \sim \frac{\overline{b}}{\frac{p}{b} + Kd}$$

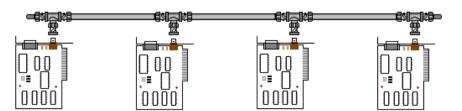

- Note:
 - For large packets, small distances, E ~ 1
 - As bandwidth increases, E decreases
 - That is why high-speed LANs are all switched aka packets are sent via a switch - (any d is bad)

Ethernet... yet another product of XEROX/PARC

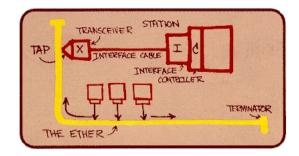

Preamble									Destination MAC						Source MAC						Ethe S	rType/ ize	PayLoad			CRC				
 1	2	3	4	5	6		7	8	1	2	3	4	5	6	1	2	3	4	5	6	1	2					1	2	3	4

Ethernet: CSMA/CD Protocol

- Carrier sense: wait for link to be idle
- Collision detection: listen while transmitting
 - No collision: transmission is complete
 - Collision: abort transmission & send jam signal
- Random access: binary exponential back-off
 - After collision, wait a random time before trying again
 - After mth collision, choose K randomly from {0, ..., 2^m-1}
 - and wait for K*512 bit times before trying again
 - Using min packet size as "slot"
 - If transmission occurring when ready to send, wait until end of transmission (CSMA)

STARVATION WARNING

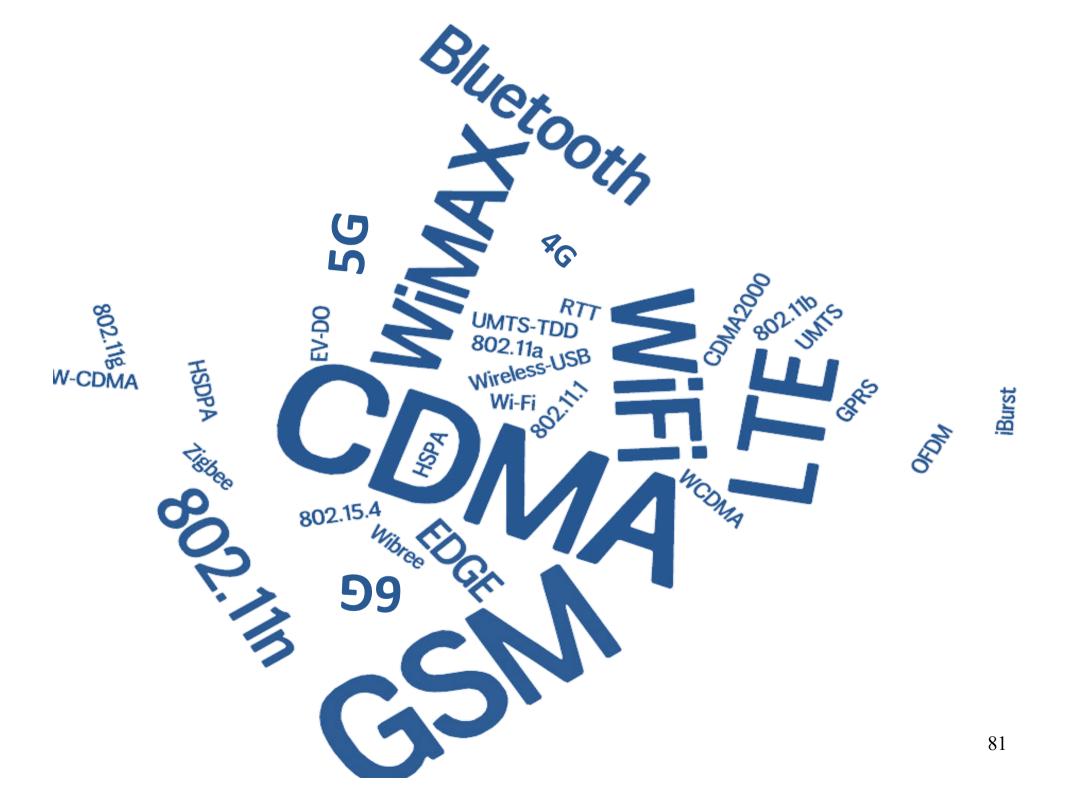

- Carrier sense: wait for link to be idle
- Collision detection: listen while transmitting
 - No collision: transmission is complete
 - Collision. abort transmission & send jam signal
- Random access: binary exponential back-off
 - After collision, wait a random time before trying again
 - After mth collision, choose K randomly from {0, ..., 2^m-1}
 - ... and wait for K*512 bit times before trying again
 - Using min packet size as "slot"
 - If transmission occurring when ready to send, wait until end of transmission (CSMA)

Benefits of Ethernet

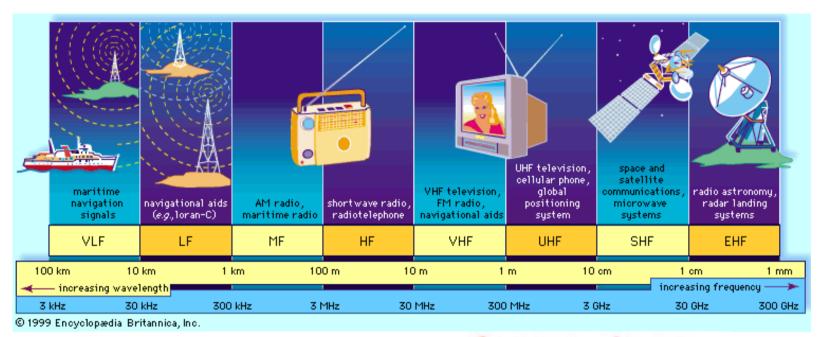

- Easy to administer and maintain
- Inexpensive
- Increasingly higher speed
- Evolvable!

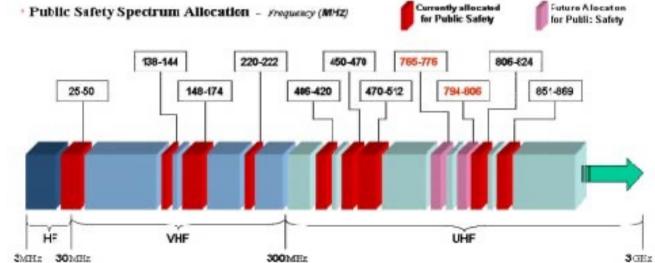

Evolution of Ethernet

- Changed everything except the frame format
 - From single coaxial cable to hub-based star
 - From shared media to switches
 - From electrical signaling to optical
- Lesson #1
 - The right interface can accommodate many changes
 - Implementation is hidden behind interface
- Lesson #2
 - Really hard to displace the dominant technology
 - Slight performance improvements are not enough

The Wireless Spectrum

82

Metrics for evaluation / comparison of wireless technologies

- Bitrate or Bandwidth
- Range PAN, LAN, MAN, WAN
- Two-way / One-way
- Multi-Access / Point-to-Point
- Digital / Analog
- Applications and industries
- Frequency Affects most physical properties: Distance (free-space loss)
 Penetration, Reflection, Absorption
 Energy proportionality
 Policy: Licensed / Deregulated
 Line of Sight (Fresnel zone)
 Size of antenna
- > Determined by wavelength $\lambda = \frac{v}{f}$,)

Wireless Communication Standards

- Cellular (800/900/1700/1800/1900Mhz):
 - 2G: GSM / CDMA / GPRS /EDGE
 - 3G: CDMA2000/UMTS/HSDPA/EVDO
 - 4G: LTE, WiMax
- IEEE 802.11 (aka WiFi): (some examples)
 - b: 2.4Ghz band, 11Mbps (~4.5 Mbps operating rate)
 - g: 2.4Ghz, 54-108Mbps (~19 Mbps operating rate)
 - a: 5.0Ghz band, 54-108Mbps (~25 Mbps operating rate)
 - n: 2.4/5Ghz, 150-600Mbps (4x4 mimo)
 - ac: 2.4/5Ghz, 433-1300Mbps (improved coding 256-QAM)
 - ad: 60Ghz, 7Gbps
 - af: 54/790Mhz, 26-35Mbps (TV whitespace)
- IEEE 802.15 lower power wireless:
 - 802.15.1: 2.4Ghz, 2.1 Mbps (Bluetooth)
 - 802.15.4: 2.4Ghz, 250 Kbps (Sensor Networks)

What Makes Wireless Different?

- Broadcast and multi-access medium...
 - err, so....

- BUT, Signals sent by sender don't always end up at receiver intact
 - Complicated physics involved, which we won't discuss
 - But what can go wrong?

Lets focus on 802.11

aka - WiFi ... What makes it special?

Deregulation > Innovation > Adoption > Lower cost = Ubiquitous technology

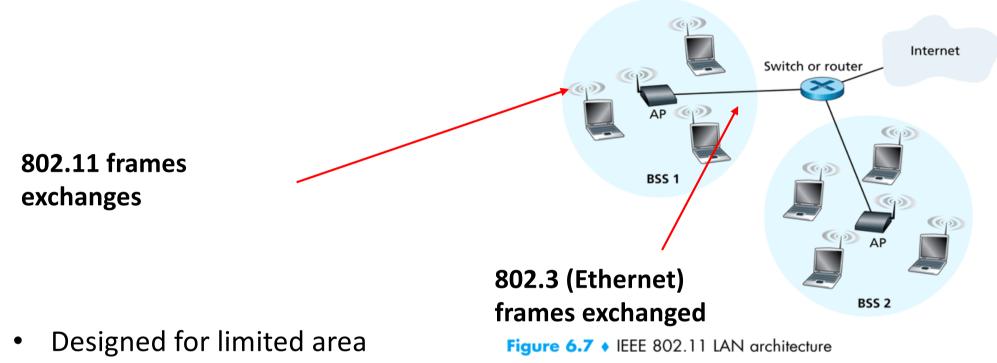

JUST LIKE ETHERNET – not lovely but sufficient

IEEE 802.11 Wireless LAN

IEEE 802.11 standard	Year	Max data rate	Range	Frequency
802.11b	1999	11 Mbps	30 m	2.4 Ghz
802.11g	2003	54 Mbps	30m	2.4 Ghz
802.11n (WiFi 4)	2009	600	70m	2.4, 5 Ghz
802.11ac (WiFi 5)	2013	3.47Gpbs	70m	5 Ghz
802.11ax (WiFi 6)	2020 (exp.)	14 Gbps	70m	2.4, 5 Ghz
802.11af	2014	35 – 560 Mbps	1 Km	unused TV bands (54-790 MHz)
802.11ah	2017	347Mbps	1 Km	900 Mhz

 all use CSMA/CA for multiple access, and have base-station and ad-hoc network versions

802.11 Architecture

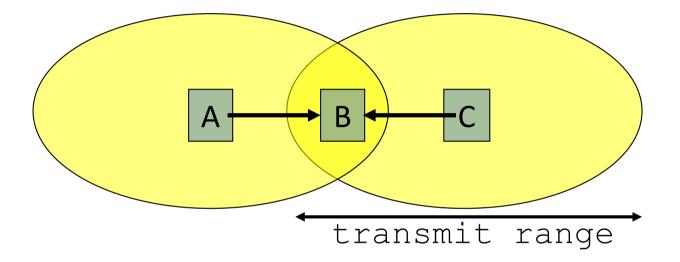

- AP's (Access Points) set to specific channel
- Broadcast beacon messages with SSID (Service Set Identifier) and MAC Address
 periodically
- Hosts scan all the channels to discover the AP's
 - Host associates with AP

Wireless Multiple Access Technique?

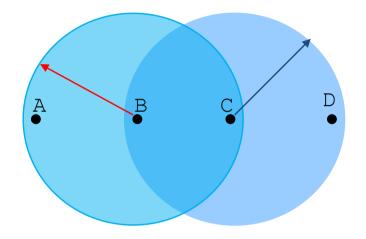

- Carrier Sense?
 - Sender can listen before sending
 - What does that tell the sender?
- Collision Detection?
 - Where do collisions occur?
 - How can you detect them?

Hidden Terminals

- A and C can both send to B but can't hear each other
 A is a hidden terminal for C and vice versa
- Carrier Sense will be ineffective

Exposed Terminals

- Exposed node: B sends a packet to A; C hears this and decides not to send a packet to D (despite the fact that this will not cause interference)!
- Carrier sense would prevent a successful transmission.

Key Points

- No concept of a global collision
 - Different receivers hear different signals
 - Different senders reach different receivers
- Collisions are at receiver, not sender
 - Only care if receiver can hear the sender clearly
 - It does not matter if sender can hear someone else
 - As long as that signal does not interfere with receiver
- Goal of protocol:
 - Detect if receiver can hear sender
 - Tell senders who might interfere with receiver to shut up

Basic Collision Avoidance

- Since can't detect collisions, we try to avoid them
- Carrier sense:
 - When medium busy, choose random interval
 - Wait that many **idle** timeslots to pass before sending
- When a collision is inferred, retransmit with binary exponential backoff (like Ethernet)
 - Use ACK from receiver to infer "no collision"
 - Use exponential backoff to adapt contention window

IEEE 802.11 MAC Protocol: CSMA/CA

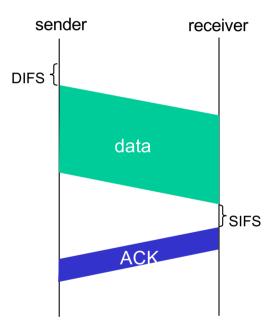

802.11 sender

- 1 if sense channel idle for **DIFS** then transmit entire frame (no CD)
- 2 if sense channel busy then start random backoff time timer counts down while channel idle transmit when timer expires if no ACK, increase random backoff interval, repeat 2

802.11 receiver

if frame received OK

return ACK after **SIFS** (ACK needed due to hidden terminal problem)

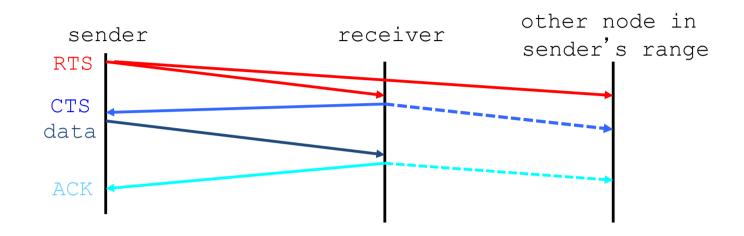

Avoiding collisions

idea: sender "reserves" channel use for data frames using small reservation packets

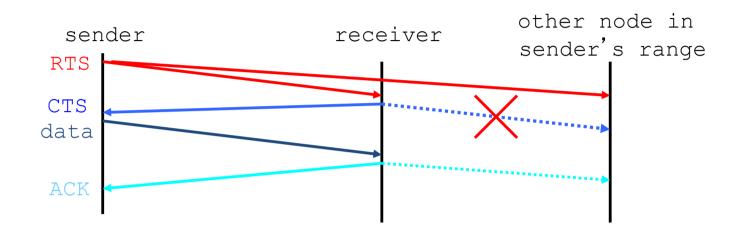

- sender first transmits small request-to-send (RTS) packet to BS using CSMA
 - RTSs may still collide with each other (but they're short)
- BS broadcasts clear-to-send CTS in response to RTS
- CTS heard by all nodes
 - sender transmits data frame
 - other stations defer transmissions

CSMA/CA – and in this case RTS/CTS

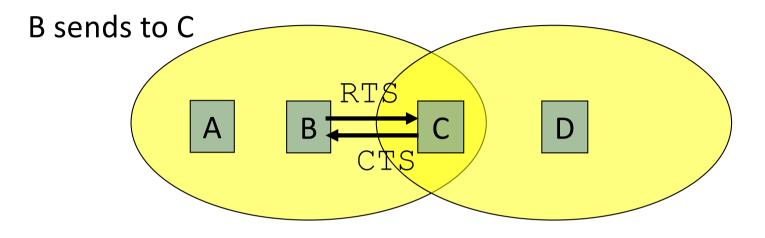

- Before every data transmission
 - Sender sends a Request to Send (RTS) frame containing the length of the transmission
 - Receiver respond with a Clear to Send (CTS) frame
 - Sender sends data
 - Receiver sends an ACK; now another sender can send data
- When sender doesn't get a CTS back, it assumes collision

CSMA/CA, con't

- If other nodes hear RTS, but not CTS: send
 - Presumably, destination for first sender is out of node's range ...
 - … Can cause problems when a CTS is lost
- When you hear a CTS, you keep quiet until scheduled transmission is over (hear ACK)

RTS / CTS Protocols (CSMA/CA)

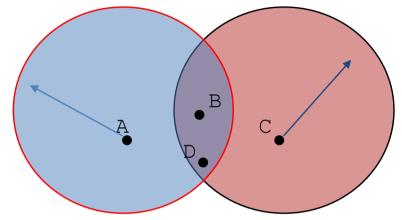

Overcome hidden terminal problems with contention-free protocol

- 1. B sends to C Request To Send (RTS)
- 2. A hears RTS and defers (to allow C to answer)
- 3. C replies to B with Clear To Send (CTS)
- 4. D hears CTS and defers to allow the data
- 5. B sends to C

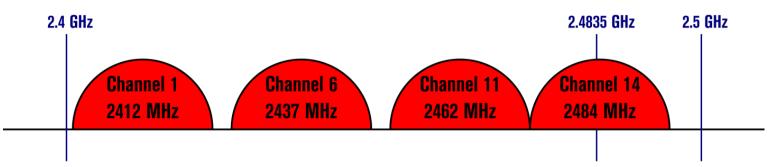

Preventing Collisions Altogether

- Frequency Spectrum partitioned into several channels
 - Nodes within interference range can use separate channels

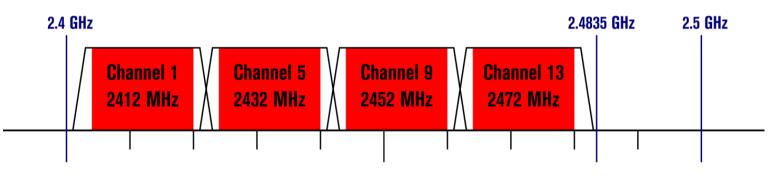

- Now A and C can send without any interference!
- Most cards have only 1 transceiver
 - Not Full Duplex: Cannot send and receive at the same time
 - Aggregate Network throughput doubles

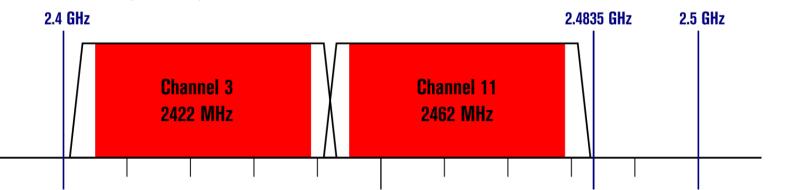

Non-Overlapping Channels for 2.4 GHz WLAN 802.11b (DSSS) channel width 22 MHz

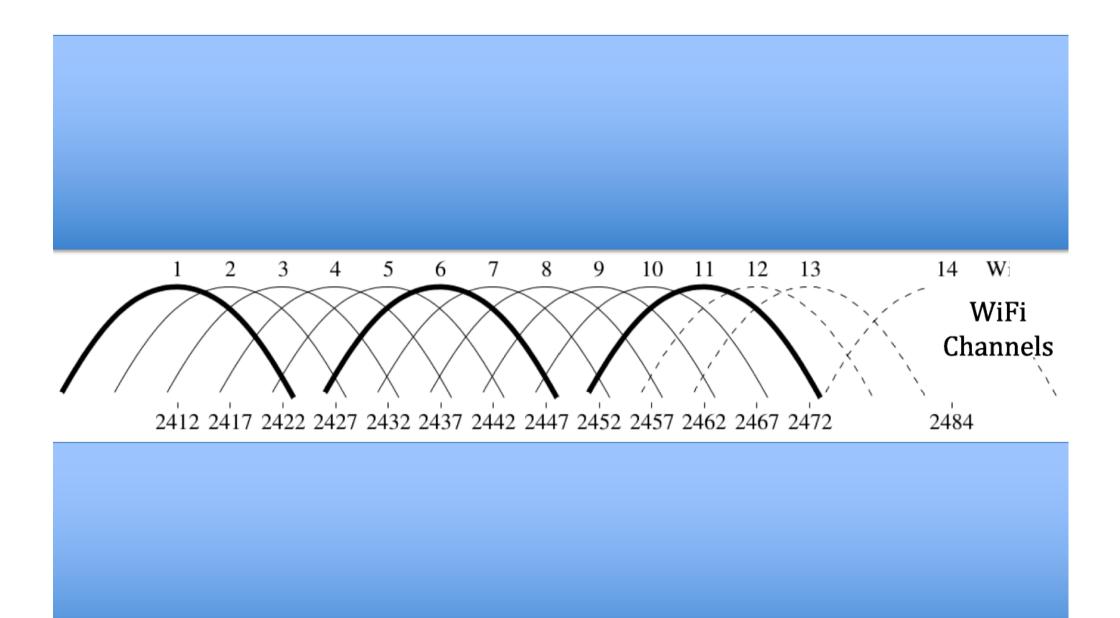

802.11g/n (OFDM) 20 MHz ch. width – 16.25 MHz used by sub-carriers

802.11n (OFDM) 40 MHz ch. width – 33.75 MHz used by sub-carriers

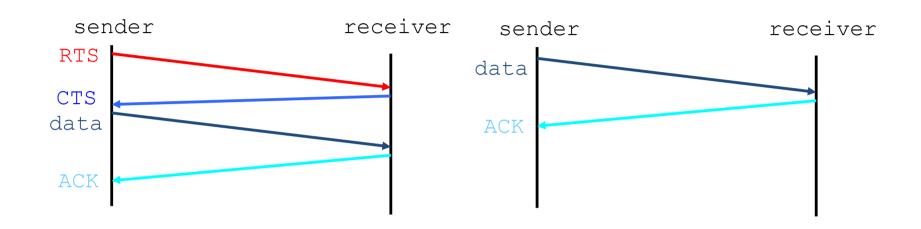

Wifi has been evolving!

Using dual band (2.4GHz + 5GHz), multiple channels, MIMO, Meshing WiFi

Outside this introduction but the state of the art is very fast and very flexible

CSMA/CA and RTS/CTS

RTS/CTS

- helps with hidden terminal
- good for high-traffic Access Points
- often turned on/off dynamically

Without RTS/CTS

- lower latency -> faster!
- reduces wasted b/w if the *Pr(collision)* is low
- good for when net is small and not *weird* eg no hidden/exposed terminals

CSMA/CD vs CSMA/CA (without RTS/CTS)

CD Collision Detect

wired – listen and talk

- 1. Listen for others
- 2. Busy? goto 1.
- 3. Send message (and listen)
- 4. Collision?
 - a. JAM
 - b. increase your BEB
 - c. sleep
 - d. goto 1.

CA Collision Avoidance

wireless - talk OR listen

- 1. Listen for others
- 2. Busy? goto 1.
- 3. Send message
- 4. Wait for ACK (MAC ACK)
- 5. Got No ACK from MAC?
 - a. increase your BEB
 - b. sleep
 - c. goto 1.

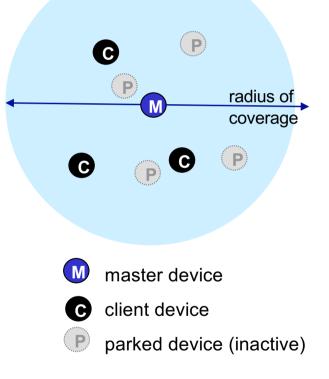

802.11: advanced capabilities

power management

- node-to-AP: "I am going to sleep until next beacon frame"
 - AP knows not to transmit frames to this node
 - node wakes up before next beacon frame
- beacon frame: contains list of mobiles with AP-to-mobile frames waiting to be sent
 - node will stay awake if AP-to-mobile frames to be sent; otherwise sleep again until next beacon frame

Personal area networks: Bluetooth

- TDM, 625 μsec sec. slot
- FDM: sender uses 79 frequency channels in known, pseudo-random order slot-to-slot (spread spectrum)
 - other devices/equipment not in piconet only interfere in some slots
- parked mode: clients can "go to sleep" (park) and later wakeup (to preserve battery)
- bootstrapping: nodes self-assemble (plug and play) into piconet

Summary of MAC protocols

- *channel partitioning,* by time, frequency or code
 - Time Division (TDMA), Frequency Division (FDMA), Code Division (CDMA)
- random access (dynamic),
 - ALOHA, S-ALOHA, CSMA, CSMA/CD
 - carrier sensing: easy in some technologies (wire), hard in others (wireless)
 - CSMA/CD used in (old-style, coax) Ethernet, and PowerLine
 - CSMA/CA used in 802.11
- taking turns
 - polling from central site, token passing
 - Bluetooth, FDDI, IBM Token Ring

MAC Addresses

- MAC (or LAN or physical or Ethernet) address:
 - function: get frame from one interface to another physically-connected interface (same network)
 - 48 bit MAC address (for most LANs)
 - burned in NIC ROM, nowadays usually software settable and set at boot time

awm22@rio:~\$ ifconfig eth0
eth0 Link encap:Ethernet HWaddr 00:30:48:fe:c0:64
inet addr:128.232.33.4 Pcast:128.232.47 255 Mask:255.255.240.0
inet6 addr: fe80::230:48ff:fefe:c064/64 Scope:Link
UP BROADCAST RUNNING MULTICAST MTU:1500 Metric:1
RX packets:215084512 errors:252 dropped:25 overruns:0 frame:123
TX packets:146711866 errors:0 dropped:0 overruns:0 carrier:0
collisions:0 txqueuelen:1000
RX bytes:170815941033 (170.8 GB) TX bytes:86755864270 (86.7 GB)
Memory:f000000-f0020000

LAN Address (more)

- MAC address allocation administered by IEEE
- manufacturer buys portion of MAC address space (to assure uniqueness)
- analogy:

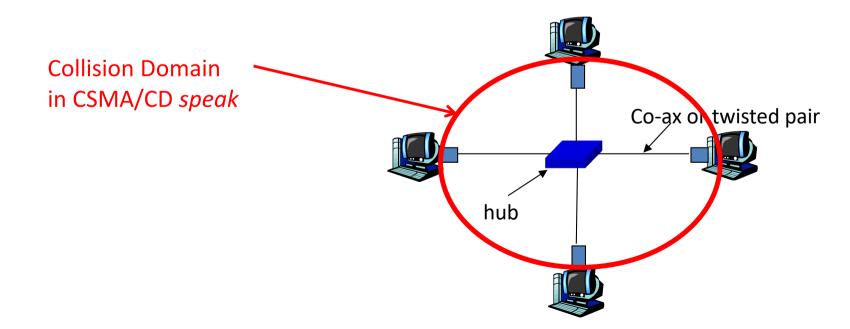

(a) MAC address: like a National Insurance Number(b) IP address: like a postal address

- MAC flat address → portability
 - can move LAN card from one LAN to another
- IP hierarchical address NOT portable
 - address depends on IP subnet to which node is attached

Hubs

... physical-layer ("dumb") repeaters:

- bits coming in one link go out *all* other links at same rate
- all nodes connected to hub can collide with one another
- no frame buffering
- no CSMA/CD at hub: host NICs detect collisions

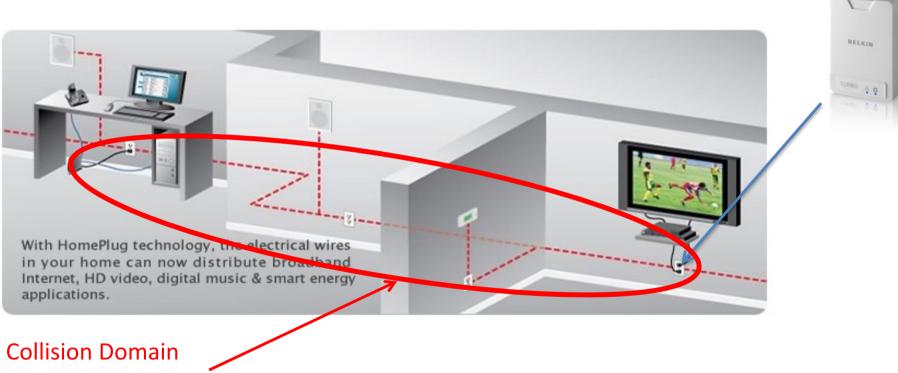

CSMA in our home

Home Plug Powerline Networking....

Home Plug and similar Powerline Networking....

in CSMA *speak*

To secure network traffic on a specific HomePlug network, each set of adapters use an encryption key common to a specific HomePlug network

Switch (example: Ethernet Switch)

- link-layer device: smarter than hubs, take active role
 - store, forward Ethernet frames
 - examine incoming frame's MAC address, selectively forward frame to one-or-more outgoing links when frame is to be forwarded on segment, uses CSMA/CD to access segment
- transparent
 - hosts are unaware of presence of switches
- plug-and-play, self-learning
 - switches do not need to be configured

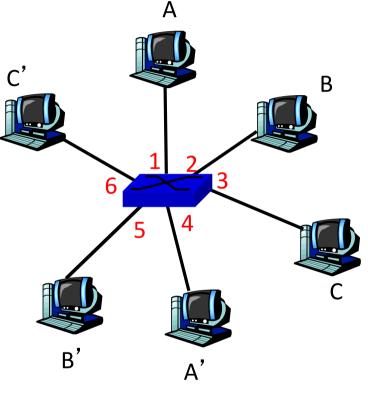

If you want to connect different physical media (optical – copper – coax – wireless -)

you **NEED** a switch.

Why? (Because each link, each media access protocol is specialised)

Switch: allows *multiple* simultaneous transmissions

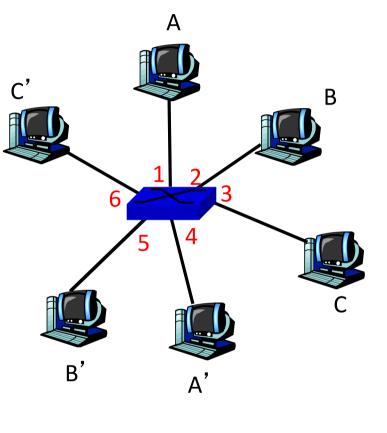

- hosts have dedicated, direct connection to switch
- switches buffer packets
- Ethernet protocol used on *each* incoming link, but no collisions; full duplex
 - each link is its own collision domain
- switching: A-to-A' and B-to-B' simultaneously, without collisions
 - not possible with dumb hub

switch with six interfaces (1,2,3,4,5,6)

Switch Table

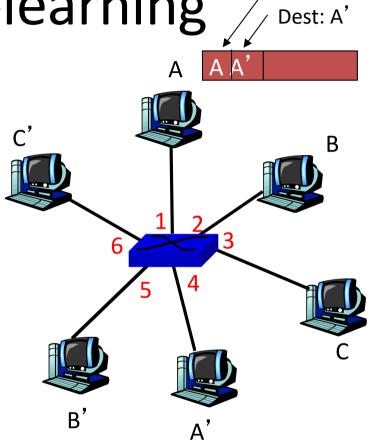

- <u>Q</u>: how does switch know that A' reachable via interface 4, B' reachable via interface 5?
- <u>A:</u> each switch has a switch table, each entry:
 - (MAC address of host, interface to reach host, time stamp)
- looks like a routing table!
- <u>Q</u>: how are entries created, maintained in switch table?
 - something like a routing protocol?

switch with six interfaces (1,2,3,4,5,6)

Switch: self-learning

- switch *learns* which hosts can be reached through which interfaces
 - when frame received, switch "learns" location of sender: incoming LAN segment
 - records sender/location pair in switch table

MAC addr	interface	TTL
A	1	60

Switch table (initially empty)

Source: A

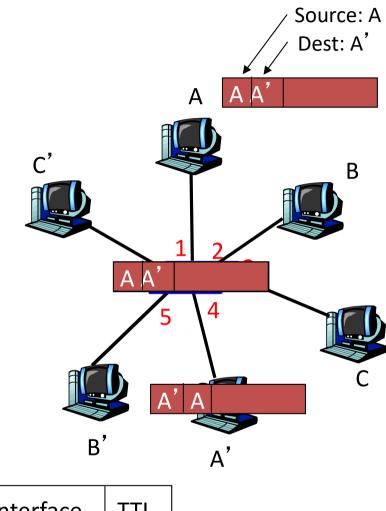

Switch: frame filtering/forwarding

When frame received:

- 1. record link associated with sending host
- 2. index switch table using MAC dest address
- 3. if entry found for destination
 then {
 - if dest on segment from which frame arrived then drop the frame
 - else forward the frame on interface indicated
 - else flood

forward on all but the interface on which the frame arrived Self-learning, forwarding: example

- frame destination unknown: *flood*
- r destination A location known: selective send

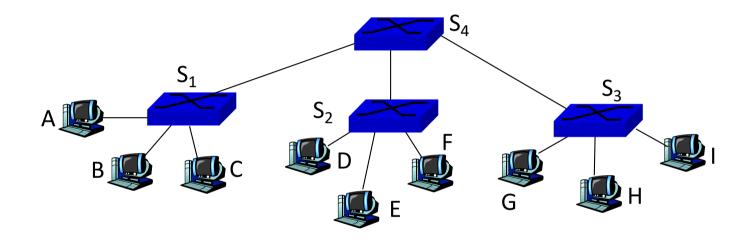

MAC addr	interface	TTL
A	1	60
A'	4	60

Switch table (initially empty)

Interconnecting switches

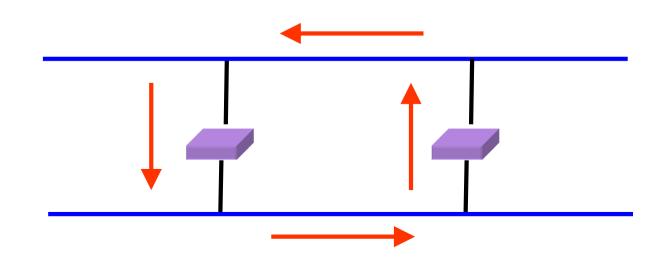

• switches can be connected together

- r Q: sending from A to G how does S₁ know to forward frame destined to F via S₄ and S₃?
- r <u>A:</u> self learning! (works exactly the same as in single-switch case flood/forward/drop)

Flooding Can Lead to Loops

- Flooding can lead to forwarding loops
 - E.g., if the network contains a cycle of switches
 - "Broadcast storm"

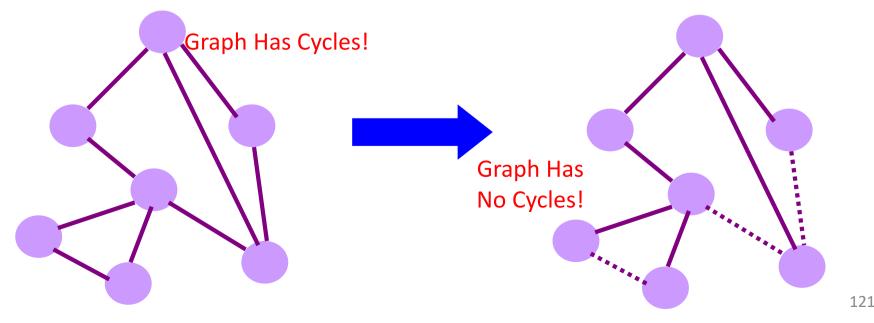

Solution: Spanning Trees

- Ensure the forwarding topology has no loops
 - Avoid using some of the links when flooding
 - to prevent loop from forming
- Spanning tree

WWF

- Sub-graph that covers all vertices but contains no cycles
- Links not in the spanning tree do not forward frames

What Do We Know?

- "Spanning tree algorithm is an algorithm to create a tree out of a graph that includes all nodes with a minimum number of edges connecting to vertices."
- Shortest paths to (or from) a node form a tree
- So, algorithm has two aspects :
 - Pick a root
 - Compute shortest paths to it
- Only keep the links on shortest-path

Constructing a Spanning Tree

- Switches need to elect a root
 - The switch w/ smallest identifier (MAC addr)
- Each switch determines if each interface is on the shortest path from the root
 - Excludes it from the tree if not

root

- Messages (Y, d, X)
 - From node X
 - Proposing Y as the root
 - And the distance is d One hop

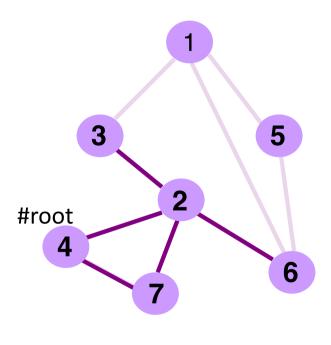

Three hops²³

Steps in Spanning Tree Algorithm

- Initially, each switch proposes itself as the root
 - Switch sends a message out every interface
 - proposing itself as the root with distance 0
 - Example: switch X announces (X, 0, X)
- Switches update their view of the root
 - Upon receiving message (Y, d, Z) from Z, check Y's id
 - If new id smaller, start viewing that switch as root
- Switches compute their distance from the root
 - Add 1 to the distance received from a neighbor
 - Identify interfaces not on shortest path to the root
 - ... and exclude them from the spanning tree
- If root or shortest distance to it changed, "flood" updated message (Y, d+1, X)

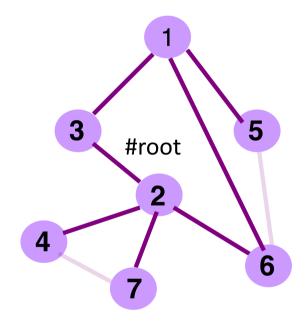

Example From Switch #4's Viewpoint

- Switch #4 thinks it is the root
 - Sends (4, 0, 4) message to 2 and 7
- Then, switch #4 hears from #2
 - Receives (2, 0, 2) message from 2
 - … and thinks that #2 is the root
 - And realizes it is just one hop away
- Then, switch #4 hears from #7
 - Receives (2, 1, 7) from 7
 - And realizes this is a longer path
 - So, prefers its own one-hop path
 - And removes 4-7 link from the tree

Example From Switch #4's Viewpoint

- Switch #2 hears about switch #1
 - Switch 2 hears (1, 1, 3) from 3
 - Switch 2 starts treating 1 as root
 - And sends (1, 2, 2) to neighbors
- Switch #4 hears from switch #2
 - Switch 4 starts treating 1 as root
 - And sends (1, 3, 4) to neighbors
- Switch #4 hears from switch #7
 - Switch 4 receives (1, 3, 7) from 7
 - And realizes this is a longer path
 - So, prefers its own three-hop path
 - And removes 4-7 link from the tree

Robust Spanning Tree Algorithm

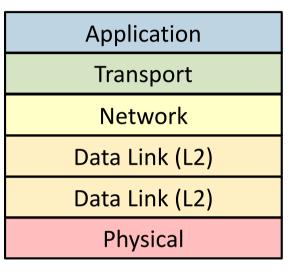

- Algorithm must react to failures
 - Failure of the root node
 - · Need to elect a new root, with the next lowest identifier
 - Failure of other switches and links
 - Need to recompute the spanning tree
- Root switch continues sending messages
 - Periodically reannouncing itself as the root (1, 0, 1)
 - Other switches continue forwarding messages
- Detecting failures through timeout (soft state)
 - If no word from root, times out and claims to be the root
 - Delay in reestablishing spanning tree is *major problem*
 - Work on rapid spanning tree algorithms...

Given a switch-tree of a given size, link length, speed of computation, ...

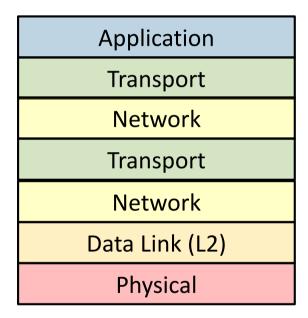

How long does a failure take to rectify?

VPN

Datacenter

"so you think your LAN has a lot of computers...."

Datacenter networks

10's to 100's of thousands of hosts, often closely coupled, in close proximity:

- e-business (e.g. Amazon)
- content-servers (e.g., YouTube, Akamai, Apple, Microsoft)
- search engines, data mining (e.g., Google)

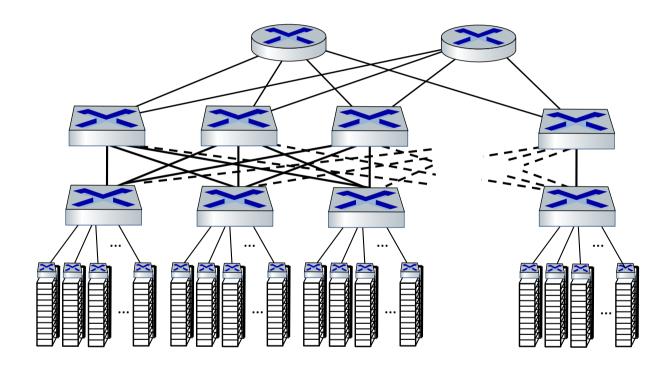

challenges:

- multiple applications, each serving massive numbers of clients
- reliability
- managing/balancing load, avoiding processing, networking, data bottlenecks

Inside a 40-ft Microsoft container, Chicago data center
