What is lexing?

Lexing

Regexes

NFA, DFA

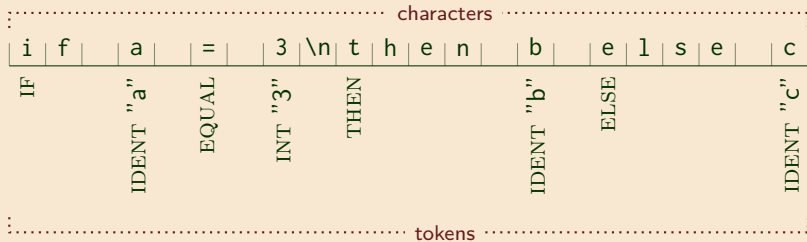

RE → NFA

NFA → DFA

Lexing
(reprise)

∂

Lexing converts a sequence of characters into a sequence of tokens.

What do lexers look like?

Lexing

Regexes

NFA, DFA

RE → NFA

NFA → DFA

Lexing
(reprise)

A **lexer** is typically specified as a sequence mapping regexes to tokens:

regular expressions	if	⇒	IF	tokens
	then	⇒	THEN	
	else	⇒	ELSE	
	=	⇒	EQUAL	
	[a-zA-Z]+ as s	⇒	IDENT s	
	[0-9]+ as i	⇒	INT i	
	[\t\n]	⇒	skip	

Token data type:

```
type token =  
  INT of int  
| IDENT of string  
| EQUAL  
| IF  
| THEN  
| ELSE  
| ...
```

Today's Q: how can we turn this *declarative specification* into a *program*?

Regular expressions

("regexes")

Lexing

Regexes

NFA, DFA

RE $\rightarrow$ NFA

NFA $\rightarrow$ DFA

Lexing
(reprise)

∂

Regular expressions e over alphabet Σ are written:

$$e \rightarrow \emptyset \mid \epsilon \mid a \mid e \vee e \mid ee \mid e^* \quad (a \in \Sigma)$$

A regular expression e denotes a **language** (set of strings) $L(e)$. For example,

$$L((a \vee b)^* abb) = \{abb, \\ aabb, \\ babb, \\ aaabb, \\ ababb, \\ baabb, \\ bbabb, \\ aaaabb, \\ \dots\}$$

The regular language problem

Lexing

Regexes

NFA, DFA

RE $\rightarrow$ NFA

NFA $\rightarrow$ DFA

Lexing
(reprise)

∂

The $L(-)$ function can be defined inductively:

$$L(e) \subseteq \Sigma^*$$

$$L(\emptyset) = \{\}$$

$$L(\epsilon) = \{\epsilon\}$$

$$L(a) = \{a\}$$

$$L(e_1 \vee e_2) = L(e_1) \cup L(e_2)$$

$$L(e_1 e_2) = \{w_1 w_2 \mid w_1 \in L(e_1), w_2 \in L(e_2)\}$$

$$L(e^0) = \{\epsilon\}$$

$$L(e^{n+1}) = L(e e^n)$$

$$L(e^*) = \bigcup_{n \geq 0} L(e^n)$$

The **regular language problem**: is $w \in L(e)$? This is **insufficient for lexing**.

Finite-state automata

Regexes

NFA, DFA

RE $\rightarrow$ NFANFA $\rightarrow$ DFALexing
(reprise) ∂

The **powerset construction** takes a NFA

$$M = \langle Q, \Sigma, \delta, q_0, F \rangle$$

and constructs a DFA

$$M' = \langle Q', \Sigma', \delta', q'_0, F' \rangle$$

where the components of M' are calculated as follows:

$$Q' = \{S \mid S \subseteq Q\}$$

$$\delta'(S, a) = \epsilon\text{-closure}(\{q' \in \delta(q, a) \mid q \in S\})$$

$$q'_0 = \epsilon\text{-closure}\{q_0\}$$

$$F' = \{S \subseteq Q \mid S \cap F \neq \emptyset\}$$

and the ϵ -closure is:

$$\epsilon\text{-closure}(S) = \{q' \in Q \mid \exists q \in S, q \xrightarrow{\epsilon} q'\}$$

How do we compute ϵ -closure(S)?

Lexing

Regexes

NFA, DFA

∂

powerset construction

The lexing problem

The lexing problem

Lexing

The **regular language problem** (i.e. “is $w \in L(e)$?”) is **insufficient for lexing**.
We need to tokenize a string using a lexer specification

i	f		a	=		3	\n	t	h	e	n		b		e	l	s	e		c		if	⇒	IF
IF			IDENT "a"	EQUAL		INT "3"	THEN						IDENT "b"		ELSE					IDENT "c"		...		
																						[a-zA-Z]+ as s	⇒	IDENT s
																						[0-9]+ as i	⇒	INT i
																						[\t\n]	⇒	skip

taking into account that

We should **skip whitespace**
(because whitespace is irrelevant to the parser)

We should find the **longest match** accepted by the lexer
(treat ifif as a variable, not two keywords)

We should pick the **first rule that matches** the longest matched substring
(treat if as a keyword because the IF rule comes before the IDENT rule)

Lexing
(reprise)

∂

Define tokens with regexes (automata)

Lexing

Regexes

NFA, DFA

RE $\rightarrow$ NFA

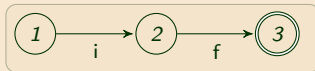

NFA $\rightarrow$ DFA

Lexing
(reprise)

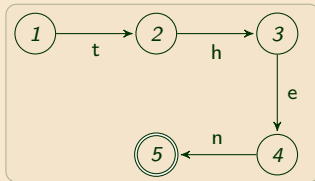

∂

if

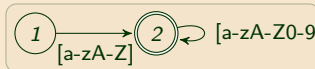

$\Rightarrow$ IF

then

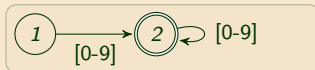

$\Rightarrow$ THEN

$[a-zA-Z][a-zA-Z0-9]^*$

$\Rightarrow$ IDENT s

$[0-9][0-9]^*$

$\Rightarrow$ INT n

$[\backslash t \backslash n]$

$\Rightarrow$ *skip*
(not really a token)

Constructing a Lexer

Lexing

Start from ordered lexer rules $e_1 \Rightarrow t_1, e_2 \Rightarrow t_2, \dots, e_k \Rightarrow t_k$.

Construct *tagged NFA* for $e_1 \vee e_2 \vee \dots \vee e_k$.

Regexes

Convert to *tagged DFA*: each accepting state is tagged for highest priority e_i .

NFA, DFA

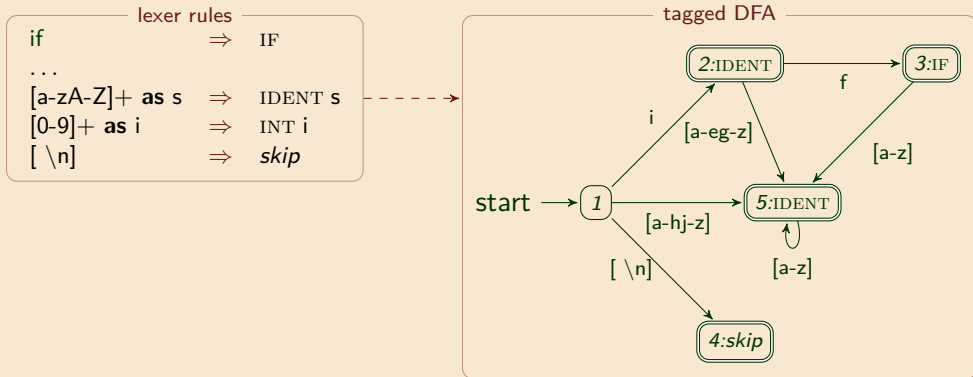

RE $\rightarrow$ NFA

NFA $\rightarrow$ DFA

Lexing
(reprise)

∂

State 3 could be either an IDENT or the keyword IF.

Priority eliminates the ambiguity, associating state 3 with the keyword.

What about longest match?

Lexing

Regexes

NFA, DFA

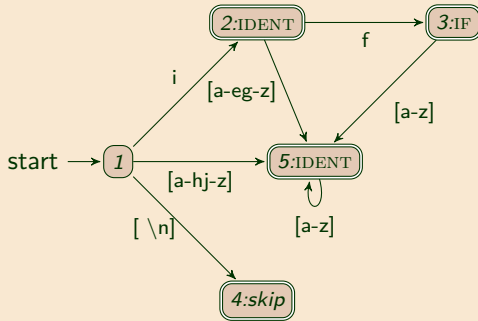

RE → NFA

NFA → DFA

Lexing
(reprise)

∂

lexing algorithm

Start in initial state, and repeatedly:

1. Read input until failure (no transition)
Emit tag for last accepting state
2. Reset state to start state
Reset position to last accepting position

tokens: IF IDENT ifx

Note: the machine is deterministic, but **the algorithm can backtrack.**

Lexing with derivatives

Matching with derivatives

Lexing

Brzozowski (1964)'s formulation of regex matching, based on *derivatives*.

Regexes

Derivative of regex r w.r.t. character c is
another regex $\partial_c r$ that matches s iff r matches cs .

NFA, DFA

E.g.: consider $(b \vee c)^+$. After matching c , can accept either ϵ or more b/c , so:

RE $\rightarrow$ NFA

$$\partial_c (b \vee c)^+ = \epsilon \vee (b \vee c)^+ = (b \vee c)^*$$

NFA $\rightarrow$ DFA

Construct DFA for r , taking regexes r as states, adding transition $r_i \xrightarrow{c} r_j$ whenever $\partial_c r_i = r_j$. For example, for $(b \vee c)^+$:

Lexing
(reprise)

∂
● ○ ○

NB: $\partial_c (b \vee c)^* = (b \vee c)^*$. (Can you see why?) Also: ϵ -matching states are accepting.

Lexing

∂_c is defined inductively over regexes.

Regexes

Can you see the similarities with derivatives of numerical functions?

(**Hint:** read $r_1 r_2$ as $r_1 \times r_2$ and $r_1 \vee r_2$ as $r_1 + r_2$.)

NFA, DFA

$$\partial_c \emptyset = \emptyset$$

$$\partial_c \epsilon = \emptyset$$

$$\partial_c b = \emptyset$$

$$\partial_c c = \epsilon$$

RE $\rightarrow$ NFA

$$\partial_c (rs) = (\partial_c r)s \mid \nu(r)(\partial_c s) \qquad \nu(r) = \epsilon \text{ if } \epsilon \in L(r)$$

$$\partial_c (r \vee s) = \partial_c r \vee \partial_c s \qquad = \emptyset \text{ if } \epsilon \notin L(r)$$

NFA $\rightarrow$ DFA

$$\partial_c r^* = (\partial_c r)r^*$$

Lexing
(reprise)

More information: *Regular-expression derivatives re-examined (Owens et al, 2009).*

Lexing with derivatives

Lexing

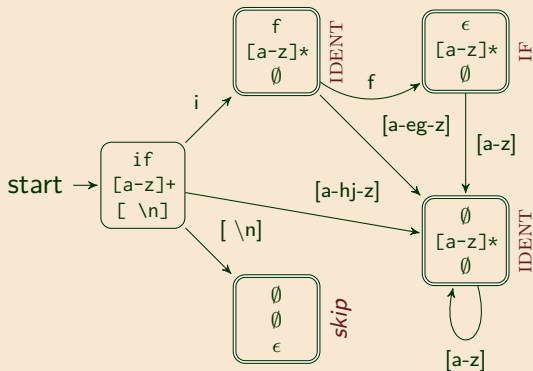

Lexers match input string against multiple regexes in parallel.

Regexes

Automaton for matching a token; states are vectors of regexes, one per lexer rule.

∂_c acts pointwise on the regex vector.

NFA, DFA

Lexing
