

2008 Paper 10 Question 6

Introduction to Functional Programming

(a) Write an SML function

```
propercuts: ( $\alpha$  list)  $\rightarrow$  ( $\alpha$  list *  $\alpha$  list) list
```

that given a list ℓ outputs the list of all pairs of non-empty lists (ℓ_1, ℓ_2) such that $\ell_1 @ \ell_2 = \ell$. [5 marks]

(b) Consider the following datatypes

```
datatype  $\alpha$  tree = leaf of  $\alpha$  | node of  $\alpha$  tree *  $\alpha$  tree ;
```

```
datatype  $\alpha$  symbol = Lbracket | Rbracket | token of  $\alpha$  ;
```

and the SML function

```
rep:  $\alpha$  tree  $\rightarrow$  ( $\alpha$  symbol) list
```

that represents a binary tree as a list of symbols, according to the following definition:

```
fun rep ( leaf x ) = [ token x ]  
  | rep ( node(l,r) )  
    = [ Lbracket ] @ (rep l) @ (rep r) @ [ Rbracket ] ;
```

Write an SML function

```
istree: ( $\alpha$  symbol) list  $\rightarrow$  bool
```

that given a list of symbols ℓ outputs `true` if there exists a (necessarily unique) tree t such that `rep(t) = ℓ` , and outputs `false` otherwise. [10 marks]

(c) Define the SML functions

```
infix @ ;  
@:  $\alpha$  list *  $\alpha$  list  $\rightarrow$   $\alpha$  list ;
```

```
map: ( $\alpha \rightarrow \beta$ )  $\rightarrow$   $\alpha$  list  $\rightarrow$   $\beta$  list ;
```

and rigorously argue for the correctness of the following identity:

```
map f ( $\ell_1 @ \ell_2$ ) = (map f  $\ell_1$ ) @ (map f  $\ell_2$ ) :  $\beta$  list
```

for all $f : \alpha \rightarrow \beta$ and $\ell_1, \ell_2 : \alpha$ list.

[5 marks]
