

## 2008 Paper 1 Question 6

### Foundations of Computer Science

A puzzle, or one-person game, can be represented in ML by two functions:

- a next-state function, which maps a state to a list of possible next states, and
- a wins function, which returns true if the given state counts as a win.

A simple example is a puzzle that has states consisting of positive integers, a next-state function that maps  $n$  to  $[n + 2, n + 5]$ , and a “wins” function that returns true if  $n = 10$ . We can win if we start from  $n = 2$  but not from  $n = 7$ .

- (a) Code a polymorphic datatype `'a puzzle`, to represent a puzzle by the pair of a next-state function and a wins function. [2 marks]
- (b) Briefly contrast depth-first search, breadth-first search and iterative deepening as techniques for solving such puzzles. [6 marks]
- (c) Write a function `depth` that accepts a puzzle, a state and a depth limit. It should use depth-first search to determine whether the puzzle can be solved from the given state within the given depth limit. [6 marks]
- (d) Write a function `breadth` that accepts a puzzle and a state. It should use breadth-first search to determine whether the puzzle can be solved from the given state. [6 marks]

All code must be explained clearly. You may assume that any necessary ML data structures or functions are available.
