Programming metalogics
with a fixpoint type

Roy Luis Crole

February 1992
Abstract

This University of Cambridge Computer Laboratory Technical Report is a revised version of my Ph.D. thesis. The report is essentially the same as my original thesis which was completed in July 1991, with corrections and alterations as suggested by my Ph.D. examiners,

Dr. J.M.E. Hyland,
Department of Pure Mathematics and Mathematical Statistics,
Cambridge,
England

and

Prof. E. Moggi,
Dip. di Matematica,
Univ. di Genova,
Italy.

I have also made some modifications which I personally think improves the presentation of my original thesis. Any errors which remain are my sole responsibility.

Summary of Contents

A programming metalogic is a formal system into which programming languages can be translated and given meaning. The translation should both reflect the structure of the language and make it easy to prove properties of programs. This thesis develops certain metalogics using techniques of category theory and treats recursion in a new way.

The notion of a category with fixpoint object is defined. Corresponding to this categorical structure there are type theoretic equational rules which will be present in all of the metalogics considered. These rules define the fixpoint type which will allow the interpretation of recursive declarations. With these core notions FIX categories are defined. These are the categorical equivalent of an equational logic which can be viewed as a very basic programming metalogic. Recursion is treated both syntactically and categorically.

The expressive power of the equational logic is increased by embedding it in an intutionistic predicate calculus, giving rise to the FIX logic. This contains propositions about the evaluation of computations to values and an induction principle which is
derived from the definition of a fixpoint object as an initial algebra. The categorical structure which accompanies the FIX logic is defined, called a FIX hyperdoctrine, and certain existence and disjunction properties of FIX are stated. A particular FIX hyperdoctrine is constructed and used in the proof of the above properties.

PCF-style languages are translated into the FIX logic and computational adequacy results are proved. Two languages are studied: Both are similar to PCF except one has call by value recursive function declarations and the other higher order conditionals.

A dependently typed equational logic containing a fixpoint type and a universal type is given together with its related categorical structure, namely a FIX category with attributes. A representation theorem for Scott predomains is proved, which gives rise to a concrete example of such a FIX category with attributes. Recursive domain equations give rise to endofunctions on the universal type; using the fixpoint type we may solve for fixpoints of such endofunctions and thus obtain a solution of the original domain equation as the type coded by the fixpoint.

Chapter 0

Categorical Logic in Computer Science

0.1 Introduction

During the late 1960's and early 1970's Scott and Strachey, researchers in the University of Oxford, became concerned with the methods used to define programming languages, or perhaps we should say the lack of methods. At the time, the description of a language was essentially operational in nature and to some extent language definitions were virtually synonymous with actual implementations. Very little research concerning underlying mathematical theories of programming had been undertaken. In the mid 1960's, Landin noted connections between the λ calculus, a formalism developed by logicians for representing functions, and certain constructs which appear in programming languages. Landin used the formal theory of the λ calculus to guide the construction of a machine for evaluating programs [Lan64]. It is interesting to note that Landin comments "This paper is a contribution to the 'theory' of the activity of using computers." Indeed, Landin observed that the reduction rules of the λ calculus resemble certain operational reductions of commands and expressions in programming languages and his work was one of the first formal treatments of the theory of operational specifications of programming languages.

Scott and Strachey wanted to move away from operational specifications of languages and instead attempt to develop a denotational approach which concentrated more on the intended meaning of a language. A simple example of their idea is illustrated by the concept of natural number. Different languages can be used to specify natural numbers, for example octal, decimal, roman, but in each case we are really concerned with what is denoted (a natural number) and not how the natural number is represented. The first examples of denotational specifications of program fragments were worked out by Scott and Strachey; see [Sco70b], [Sco70a] and [SS71]. In pursuing the notion of mathematical models of programming languages, the question of what constitutes such a model of the λ calculus arose. The λ calculus allows syntactic expressions (which represent functions) to be applied to themselves. It was clear that a mathematical model should interpret such function-representing expressions as some form of set-theoretic function; and to model self application certain sets would have to contain their own function space. Scott realised that such a construction was possible by imposing certain conditions on the kind of function which was allowed in the model; see [Sco69a] and [Sco71]. For further examples of denotational semantics see [Sco82], [Str74] and [SW74].

Once the foundations of operational and denotational semantics had been laid down,
other researchers took up the task of attempting more formal treatments of programming semantics. It became clear that formal semantics would be necessary to ensure that programs really behaved as they were supposed to. The semantics could be used to reason about programs; in particular to prove that a program satisfies its specification. Plotkin investigated different kinds of operational semantics of the λ calculus [Plo75] and also the connections with denotational semantics [Plo77], and went on to clarify many issues which had arisen from both his work and the work of others: see [Plo80] and [Plo81].

As programs became larger and more intricate, the task of proving programs correct became much more difficult. One solution to this problem was the idea of a programming metalogic which is a formal logical system in which it is possible to give meaning to other programming languages. The programming metalogic will usually have a very rich type structure and powerful rules for reasoning and will be used to give meaning to a programming language by translating the source code into the metalogic. This translation should preserve the structure of the original language, thereby allowing properties of source programs to be proven by showing the property holds in the metalogic. A proof in the metalogic should be substantially easier than a direct proof using the semantics of the original language.

This thesis presents three such programming metalogics and describes some simple applications. Each of the metalogics deals with recursively defined declarations in a novel way, introducing a new type called the fixpoint type; see [CP90a]. The first of these metalogics is a simple equational logic which is an extension of the computational lambda calculus [Mog89b]; the latter is a formal system for programming semantics which separates the notions of computation and value. The second metalogic is a predicate logic which subsumes the original equational logic via an equality predicate. It is ideally suited to reasoning about languages presented in the natural semantics style [Kah88]. The third metalogic is a dependently typed equational logic containing a type universe: we use this to solve domain equations. The solution of a domain equation can be regarded as a recursively defined type; equivalently we may regard the equation as determining an endofunction on the type universe. We can find a fixpoint of such a function using the fixpoint type and the solution to the domain equation is the type represented by the fixpoint.

Categorical logic is the study of connections between formal logical systems and category theory. As we have remarked, logics can be used to give meaning to programming languages. Category theory can be used to guide the design of such metalogics and also to give a uniform presentation of their semantics. Often it is easier to prove a property of a metalogic by categorical means and then translate the results into statements about the metalogic. The techniques of categorical logic will be used throughout this thesis.

0.2 A Thesis Summary

This thesis divides into three parts.
• **Part I** A simple equational metalogic is described which builds upon the computational let calculus. This system will form a basic core for the metalogics described in Part II and Part III.

• **Part II** The equational metalogic of Part I is strengthened to a predicate metalogic and we give some simple applications.

• **Part III** A dependently typed equational logic containing a type universe is given; this is used to solve domain equations.

**Part I**

**Chapter 1**

We begin by giving a brief review of some basic category theory which will be used throughout this thesis, aiming to set up notation for monads, tensorial strengths and let categories. We also provide a few elementary examples of let categories which illustrate their use in computer science. For some background in categorical logic see [Law69] and [MR77].

**Chapter 2**

We review the computational let calculus and motivate both its uses and also the form in which it is usually presented. This leads to a discussion of suitable extensions and in particular to the fixpoint type: see [NPS90] for some background in type theory. In the presence of a fixpoint type certain endofunctions must have fixpoints. We introduce a categorical definition of the concept of fixpoint type, namely a fixpoint object in a let category. In such categories, morphisms of certain kinds are guaranteed to have fixpoints. This leads to the internal logic of fixpoint objects and from this we describe an extension of the computational $\lambda$ calculus which, among other things, contains the logic of a fixpoint object. This system is referred to as the $\text{FIX}_\approx$ logic.

**Chapter 3**

We define $\text{FIX}$ categories and prove the usual categorical logic correspondence between such categorical structures and $\text{FIX}_\approx$. We show that $\text{FIX}$ categories are, in a precise sense, the most general structures for interpreting $\text{FIX}_\approx$. We discuss fixpoints both in $\text{FIX}_\approx$ and in $\text{FIX}$ categories and move on to show that $\text{FIX}$ categories are functionally complete. Finally we carry out a gluing construction for let categories which will be used to prove a result about equality of ground terms in $\text{FIX}_\approx$. 
Part II

Chapter 4

The language $\text{FIX}_\infty$ captures certain computational features through an equational theory: we increase its expressiveness by embedding $\text{FIX}_\infty$ in a predicate logic called FIX. We define the notion of a FIX theory and show that the pure FIX logical system has a formulation in which some of the rules assume an adjoint form. The chapter finishes with a number of results about FIX, some of which will be put to use later on, together with the statements of three theorems concerning the metalogical properties of FIX.

Chapter 5

We define a FIX hyperdoctrine, which is the categorical counterpart of the FIX logic, and give a concrete example. The next task is to give a formal statement of the categorical logic correspondence for FIX hyperdoctrines and the FIX logic. With a view to using this correspondence to prove the metalogical properties stated in Chapter 4, we define the "logical relations hyperdoctrine;" the proofs make use of its internal logic.

Chapter 6

We investigate how well suited the FIX logic is for analysing two small programming languages. Both of these languages are based on Plotkin's PCF. We give translations of both static and dynamic semantics into the pure FIX logic and prove adequacy results which show that the translations we give preserve the structure and properties of the source languages.

Part III

Chapter 7

We extend the notion of information system to provide a representation theorem for Scott predomains; the latter have properties similar to Scott domains but do not necessarily possess a least element. To effect this, the classical definition of information system is altered in a simple way, giving rise to preinformation systems. We present canonical constructions of products, coproducts and lifting, along with partial function space, in the category of preinformation systems.

Chapter 8

We aim to develop a logic in which there is both a universal type and a fixpoint type. Domain equations can then be solved by considering the endofunctions which will be induced on the universal type. The $\text{FIX}_\infty$ equational logic forms the backbone of
the system introduced here, namely $\text{FIX}_\mu$. We describe the syntax and logical rules of $\text{FIX}_\mu$ which is a dependently typed equational logic and introduce the notion of a $\text{FIX}_\mu$ theory.

Chapter 9

A general categorical structure for dependently typed equational theories is reviewed, namely categories with attributes. We then define a $\text{FIX}$ category with attributes; such structures will be used to model $\text{FIX}_\mu$ theories. Having done this, we give a concrete example of a $\text{FIX}$ category with attributes and move on to consider the general categorical semantics of $\text{FIX}_\mu$. We finish this chapter with some basic results about such semantics.

Chapter 10

We consider what has been achieved, the prospects for further research and draw our conclusions together.

0.3 Foundation and Notation

Foundations of Category Theory

Throughout this thesis, if we say “let $\mathcal{C}$ be a category” we shall mean that we have specified interpretations of the statements “$A$ is an object of $\mathcal{C}$” and “$f$ is a morphism of $\mathcal{C}$,” along with interpretations of “identity morphism,” “domain,” “codomain” and “composition.” There will be no assumptions as to whether the collections of objects or morphisms of $\mathcal{C}$ form a set. We shall only impose restrictions on collections when it is prudent to do so. In such cases, we shall refer to the notions of small and locally small categories as appropriate and think of such concepts within a given model of set theory.

Martin-Löf’s Theory of Arities and Expressions

We shall use the theory of arities and expressions due to Martin-Löf to present the object level syntax in this thesis; to do this we make the following definition:

Definition 0.3.1 An abstract syntax signature $\Sigma$ is a pair of sets $(\text{GAr}, \text{Con})$ where the elements of $\text{GAr}$ are called ground arities and the elements of $\text{Con}$ are called constants. Regarding the ground arities as the ground types for a simply typed $\lambda$ calculus, we refer to the simple types as arities. The constants are assumed to be tagged with an arity.

With these data, we can regard the abstract syntax signature $\Sigma$ as a signature in the conventional sense for a (type tagged) simply typed $\lambda$ calculus with constants.
**Definition 0.3.2** Given an abstract syntax signature $\Sigma$, an *abstract syntax* is the collection of $\alpha \beta \eta$ equivalence classes of terms of the simply typed $\lambda$ calculus generated from $\Sigma$ and we shall refer to this calculus as the *meta $\lambda$ calculus*. We shall call individual classes *expressions* of the abstract syntax and refer to the variables of this simply typed $\lambda$ calculus as *metavariables*. Abstraction of an expression $e$ will be denoted by $u.e$ where $u$ is a metavariable, substitution for a metavariable by $e[e'/u]$ and application by $e(e')$. A multiple application $e_1(e_2)\ldots(e_n)$ will be denoted by $e_1(e_2,\ldots,e_n)$ and $\text{FV}(e)$ is the set of free metavariables of $e$.

Roughly, we shall view the syntax of object level languages as certain expressions of an abstract syntax. Usually, the set $GAr$ will consist of elements such as $\text{TERM}$ or $\text{TYPE}$. The constants $\text{Con}$ will consist of the function symbols arising from a given signature for an object level language, together with a countably infinite set of object level variables. The arity of the function symbols is specified for the particular object level language being considered; likewise for the object level variables. Then the raw syntax of an object level language will be defined as closed expressions of an abstract syntax. Thus variable binding will take place only in the meta $\lambda$ calculus and substitution of object level terms will become application in the meta $\lambda$ calculus. An exposition of the theory of arities and expressions can be found in [Cro90] or [NPS90].

**Notational Conventions**

(1) As a general convention, we shall omit typing information from morphisms, functors etc. For example, if we speak of a natural transformation $\tau$ (between a pair of bifunctors) which has components $\tau_{(A,B)}$ with domain $A \times TB$ and codomain $T(A \times B)$, then we shall often denote these data by

$$\tau: A \times TB \to T(A \times B)$$

rather than

$$\tau_{(A,B)}: A \times TB \to T(A \times B).$$

When using commutative diagrams, we shall place just enough typing information on the morphisms to make the picture unambiguous.

(2) Throughout this document, we shall use rules of the form

\[
\begin{align*}
\text{Hypothesis} \\
\text{Conclusion}
\end{align*}
\]

where "Hypothesis" and "Conclusion" are syntactic expressions. In any such rule we assume that both "Hypothesis" and "Conclusion" are well formed.

(3) If we are given a list of expressions $E_1, \ldots, E_n$, we will often abbreviate such a list by $\bar{E}$.

(4) When discussing object level languages presented using an abstract syntax, we shall not introduce formal syntactic classes to distinguish between object level
variables and metavariables, but instead rely on the context of usage to make the
distinction. For example, if $M$ and $N$ are expressions of an abstract syntax, for an
expression of the form $M[N/x]$ to be meaningful, $x$ must be a metavariable.
Chapter 1

Strong Monads and Let Categories

1.1 Introduction

Chapter 1 contains a review of some of the basic category theory which will be used throughout this thesis. The account is by no means comprehensive; it is not intended to be. We simply define some of the fundamental concepts which are relatively new to computer science and which form the backbone of almost all of the categorical structures which arise in this work. A standard reference for basic category theory is [Mac71]; additional material on monads which is particularly relevant can be found in [Man76] and [Kel82]. Those readers who are familiar with the original works on monads, strengths and enriched category theory will see that some of our basic notation is different from that used in the references. However, as our story unfolds, we hope that the choice of notation will be seen to be both appropriate and useful.

1.2 Monads and Tensorial Strengths

**Definition 1.2.1** Let $C$ be a category. Recall that a monad over $C$ is a triple $(T, \eta, \mu)$ where $T: C \to C$ is an endofunctor, $\eta: \text{Id}_C \to T$ is a natural transformation called the unit of the monad, $\mu: T^2 \to T$ is a natural transformation called the multiplication of the monad and these data satisfy the equations $\text{Id}_T = \mu \circ \eta_T$, $\text{Id}_T = \mu \circ T \eta$ (referred to by $\text{Monad}\eta$) and $\mu \circ T \mu = \mu \circ \mu_T$ (referred to by $\text{Monad}\mu$). We shall often speak just of the monad $T$.

**Definition 1.2.2** Let $C$ be a category with finite products and let $(T, \eta, \mu)$ be a monad over $C$. The monad $T$ is said to possess a tensorial strength if there is a natural transformation $\tau$ with components

$$\tau_{(A,B)}: A \times T B \longrightarrow T(A \times B)$$

which satisfy the equational identities represented by the following commutative diagrams, where $i$ and $j$ denote obvious canonical isomorphisms:
A strong monad \((T, \tau)\) is a monad \(T\) for which there is a given choice of tensorial strength \(\tau\). When no confusion can arise we refer to a strong monad \(T\).

### 1.3 The Definition of a Let Category

#### Two Definitions of a Let Category

We begin by making the following definition:

**Definition 1.3.1** A let category is specified by a category \(C\) with finite products, over which there is a strong monad \(T\).

We can give an alternative definition of let category, which will prove to be of great value to us when we study the equational logic of these categories.

**Definition 1.3.2** A let category is specified by a category \(C\) with finite products which enjoys the following properties:
• For each object $A$ in $C$, there is an object $TA$,
• for each object $A$ in $C$, there is a morphism $\eta_A: A \to TA$, and
• for each morphism $f: A \times B \to TC$, there is a morphism $\text{lift}(f): A \times TB \to TC$,
such that the following conditions are satisfied:

$$\text{lift}(g(f \times id_B)) = \text{lift}(g)(f \times id_{TB})$$ \hspace{1cm} \text{LiftS}

where $f: A \to A'$, $g: A' \times B \to TC$,

$$\text{lift}(f)(id_A \times \eta_B) = f$$ \hspace{1cm} \text{LiftB}

where $f: A \times B \to TC$,

$$\text{lift}(\eta_B \pi_2) = \pi_2'$$ \hspace{1cm} \text{LiftH}

where $\pi_2: A \times B \to B$, and

$$\text{lift}(\text{lift}(g)(\pi_1, f)) = \text{lift}(g)(\pi_1', \text{lift}(f))$$ \hspace{1cm} \text{LiftA}

where $f: A \times B \to TC$, $g: A \times C \to TD$.

We shall refer to the operation $f \mapsto \text{lift}(f)$ as lifting.

It will be useful to work with a derived operation on morphisms of $C$ which we shall refer to as the let operation. We shall write $f \mapsto \text{let}(f)$ for this. Take projections

$$\pi_1: 1 \times A \to A \hspace{1cm} \pi_2: 1 \times TA \to TA.$$}

Then the let operation is specified by

$$\begin{array}{c}
A \xrightarrow{f} TB \\
\text{TA} \xrightarrow{\pi_2^{-1}} 1 \times TA \xrightarrow{\text{lift}(\pi_1)} TB
\end{array}$$

This definition leads immediately to the following lemmas:

**Lemma 1.3.3** Suppose we are given a let category in the sense of Definition 1.3.2. Then given morphisms $f: A \to TB$ and $g: B \to TC$ the following equational identities hold:

$$\text{let}(f)\eta = f \hspace{1cm} \text{LetB}$$

$$\text{let}(\eta) = id \hspace{1cm} \text{LetH}$$

$$\text{let}(\text{let}(g)f) = \text{let}(g)\text{let}(f) \hspace{1cm} \text{LetA}$$

**Proof** A trivial calculation.

**Lemma 1.3.4** Suppose we are given a let category in the sense of Definition 1.3.2. Given morphisms $f: A \to TB$ and $g: C \times B \to TD$, then

$$\text{lift}(g)(id \times \text{let}(f)) = \text{lift}(\text{lift}(g)(id \times f))$$

**Proof** Immediate from the definitions.
Equivalence of the Definitions

The previous definitions of let categories are equivalent in the following way:

**Lemma 1.3.5** Given a let category $C$ according to Definition 1.3.1 (Definition 1.3.2), then $C$ has the structure of Definition 1.3.2 (Definition 1.3.1).

**Proof** Suppose we are given a category $C$ with the structure of Definition 1.3.1. We show $C$ has the structure of Definition 1.3.2. Definitions of the operation $T$ and morphisms $\eta_A$ are clear. The lifting operation is defined by

$$
\begin{array}{c}
A \times B \xrightarrow{f} TC \\
A \times TB \xrightarrow{\tau} T(A \times B) \xrightarrow{Tf} T^2C \xrightarrow{\mu} TC
\end{array}
$$

Now we have to check that our definition of lifting satisfies the necessary equations. Although this is essentially routine manipulation we supply the critical details; in each case we give the recipe for transforming the left-hand side of an equation to the right-hand side. $\text{Lift}_B$ follows from the naturality of $\tau$ and the functoriality of $T$. $\text{Lift}_B$ follows from $\text{Tensor}_2$, the naturality of $\eta$ and $\text{Monad}_\eta$, thus

$Lift_B$ follows from functoriality of $T$, $\text{Monad}_\eta$, naturality of $\tau$ and $\text{Tensor}_1$. To show $\text{Lift}_A$ use functoriality of $T$ followed by $\text{Monad}_\mu$ and the naturality of $\mu$. Then we need commutativity of

$$
\begin{array}{c}
A \times TB \xrightarrow{\tau} T(A \times B) \\
\langle \pi_A, \tau \rangle \xrightarrow{(*)} T\langle \pi_A, id \rangle \\
\langle \pi_A, Tf \circ \tau \rangle \xrightarrow{\tau} T(A \times (A \times B)) \xrightarrow{T\langle \pi_A, f \rangle} T(A \times TC) \\
A \times T^2C \xrightarrow{\tau} T(A \times TC)
\end{array}
$$

14
where the commutativity of (⋆) follows from

\[
\begin{array}{ccc}
A \times TB & \xrightarrow{\tau} & T(A \times B) \\
\downarrow \Delta \times \text{id} & & \downarrow T(\Delta \times \text{id}) \\
(A \times A) \times TB & \xrightarrow{\tau} & T((A \times A) \times B)) \\
\downarrow i & & \downarrow Tj \\
A \times (A \times TB) & \xrightarrow{id \times \tau} & A \times T(A \times B) & \xrightarrow{\tau} & T(A \times (A \times B))
\end{array}
\]

with the lower square an instance of \texttt{Tensor3}. Finally apply \texttt{Tensor4} to get the result.

Conversely, suppose we are given a category \(\mathcal{C}\) with the structure of Definition 1.3.2. We give the recipe for showing \(\mathcal{C}\) also has the structure of Definition 1.3.1. The action of the monad \(T\) on objects and the components of the natural transformation \(\eta\) are clear. The definition of the monad \(T\) on morphisms is given by

\[
A \xrightarrow{f} B \\
\xrightarrow{T(f)} T(A \times TB) \xrightarrow{\tau} T((A \times A) \times B)
\]

The component of the natural transformation \(\mu\) at \(A\) is \text{let}(id_{TA}) and the component of \(\tau\) at \(A\) and \(B\) is \text{lift}(\eta_{A \times B})\). We omit the routine details which verify that \((T, \eta, \mu, \tau)\) is a strong monad. \(\blacksquare\)

We have the following corollary:

**Corollary 1.3.6** Given a category \(\mathcal{C}\) over which there is a monad \(T\), then \(\mathcal{C}\) can be considered endowed with the following structure: for objects \(A\) and \(B\) of \(\mathcal{C}\) and morphism \(f: A \rightarrow TB\) there are morphisms \(\eta_A: A \rightarrow TA\) and operations \(A \mapsto TA, f \mapsto \text{let}(f)\), where the latter operation is defined by

\[
A \xrightarrow{f} TB \\
\xrightarrow{T(\eta_B f)} T(A \times TB)
\]

These data satisfy equations \text{LetB}, \text{LetH}, \text{LetA}.

Conversely, given a category \(\mathcal{C}\) endowed with such a structure, we can define a monad \(T\) by

\[
f: A \rightarrow B \\
\xrightarrow{\text{let}(\eta_B f)} TA \rightarrow TB
\]

The components of \(\eta\) are clear and the component of \(\mu\) at \(A\) is \text{let}(id_{TA}). \(\blacksquare\)

**Remark 1.3.7** The let operation arising from a monad \(T\) over a category \(\mathcal{C}\) is closely allied to the construction of the Kleisli category \(\text{Kl}(\mathcal{C})\) where composition in \(\text{Kl}(\mathcal{C})\) is given by \((f, g) \mapsto \text{let}(g)f\).
1.4 Why Let Categories?

Motivating Ideas

A fundamental slogan for the categorical semantics of programming languages is: "types are interpreted as objects in a category and terms are interpreted as morphisms." Of course, for complicated languages this basic idea is adapted in many ways, but it is a good starting point. It has been known for some time now that formal systems correspond in a precise way to certain kinds of categorical structure, for example λ calculi (which are the theoretical backbone of functional programming languages) are the internal languages of cartesian closed categories and the cartesian closed categories provide a notion of syntax-independent presentations of λ calculi.

While functional languages are based on the principles of the λ calculus, the basic reduction strategies of λ calculi such as β and η do not elegantly distinguish between certain kinds of operational semantics such as call-by-name and call-by-value. For example, there is a notion of call-by-value strategy in λ calculi where we consider values to be those expressions of the formal system which are not applications. β reduction is then restricted to instances where the operand is a value. The na"ive formal system which captures this notion of call-by-value is a little ad-hoc: for an account see [Plo75].

Thus it might be reasonable to develop a formal system which separates the notions of computation and value: this is exactly what strong monads do for us, but in the world of semantics. Given a let category C, if an object A models a type α then the object TA models computations of values of type α. This will be more clear if illustrated by example.

Examples Of Let Categories

Our examples will be over the category Set; they are lifted from [Mog89b].

Partial Computations

Given a type α, a partial computation of type α can be thought of as a program which either terminates yielding a value of type α, or which does not terminate. If values of type α are denoted by the set A, then we can denote the partial computations with values of type α by the coproduct A + {∗}. Thus we have:

1. Operation on objects A \mapsto A + {∗}.

2. Function η_A \triangleright i: A \to A+{∗} the left coproduct insertion (with right insertion j).
3. Given a function \( f: A \times B \rightarrow C + \{\ast\} \) then we define \( \text{lift}(f) \) by
\[
\text{lift}(f)(a, s) \overset{\text{def}}{=} \begin{cases} 
  f(a, b) & \text{if } s = i(b) \\
  j(\ast) & \text{otherwise}
\end{cases}
\]

Corresponding to this let category, there is a strong monad with
\[
\mu_A: (A + \{\ast\}) + \{\ast\} \rightarrow A + \{\ast\}
\]
defined by
\[
\mu_A(s) \overset{\text{def}}{=} \begin{cases} 
  r & \text{if } s = i(r), \ r \in A + \{\ast\} \\
  j(\ast) & \text{otherwise}
\end{cases}
\]
and tensorial strength
\[
\tau_{(A,B)}: A \times (B + \{\ast\}) \rightarrow (A \times B) + \{\ast\}
\]
defined by
\[
\tau_{(A,B)}(a, s) \overset{\text{def}}{=} \begin{cases} 
  i(a, b) & \text{if } s = i(b) \\
  j(\ast) & \text{otherwise}
\end{cases}
\]

The intuitive meaning of the monad multiplication \( \mu \) is that a partial computation \( P' \) of a partial computation \( P \) is defined when both \( P' \) and \( P \) are (with result given by composition of \( P' \) and \( P \)), and is otherwise undefined. The strength \( \tau \) takes a pair consisting of a value and a partial computation and returns a partial computation, say \( P \). If the original partial computation is defined, then so is \( P \), with expected value. If the original computation is undefined, then so is \( P \).

**Computations which Raise Exceptions**

Let \( E \) be a set which models certain exceptions. Then if the set \( A \) models values (of some type say \( \alpha \)) we might consider the following (categorical) model:

1. Operation on sets \( A \mapsto A + E \).
2. Function \( \eta_A \overset{\text{def}}{=} i: A \rightarrow A + E \) the left coproduct insertion.
3. Given a function \( f: A \times B \rightarrow (C + E) \) then we define \( \text{lift}(f) \) by
\[
\text{lift}(f)(a, s) \overset{\text{def}}{=} \begin{cases} 
  f(a, b) & \text{if } s = i(b) \\
  j(e) & \text{if } s = j(e)
\end{cases}
\]

The intuitive explanation of this example is similar to that for partial computations.
Computation with Side Effects in a Store S

Suppose that we are considering a model for an imperative language where the set S is to model some set of states. One such model is:

1. Operation on sets $A \mapsto S \rightarrow (A \times S)$.
2. Function $\eta_A: A \rightarrow S \rightarrow (A \times S)$ such that given $a \in A$ and $s \in S$ then $\eta_A(a)(s) \overset{\text{def}}{=} (a, s)$.
3. Given a function $f: A \times B \rightarrow (S \rightarrow (C \times S))$ then we define $\text{lift}(f)$ by

$$\text{lift}(f)(a, t) \overset{\text{def}}{=} s \mapsto f(a, \pi_1(ts))(\pi_2(ts)).$$

The intuitive meaning of the corresponding monad multiplication $\mu$ is to say that a computation which takes a state $s$ and yields a computation $c$ with side effect (i.e. new state) $s'$ may be regarded as a computation which takes a state $s$ and returns the value and state which are the result of the computation $c$ on the value $s'$. The strength $\tau$ says that a value $a$ and a computation $c$ may be regarded as a computation which takes a state $s$ and yields a pair of values, namely $a$ and the value arising from $cs$, together with the state arising from $cs$.

Non-Deterministic Computations

Given a set $A$ modeling values of type $\alpha$ we might model non-deterministic computations of type $\alpha$ via sets of possible results, namely $\mathcal{P}(A)$. A suitable model is:

1. Operation on sets $A \mapsto \mathcal{P}(A)$.
2. Function $\eta_A: A \rightarrow \mathcal{P}(A)$ such that given $a \in A$ then $\eta_A(a) \overset{\text{def}}{=} \{a\}$.
3. Given a function $f: A \times B \rightarrow \mathcal{P}(C)$ then $\text{lift}(f)$ is defined by

$$\text{lift}(f)(a, B') \overset{\text{def}}{=} \bigcup \{f(a, b') \mid b' \in B'\}.$$

We regard the denotation of a non-deterministic computation as the collection of all possible outputs. Any value can be trivially regarded as a non-deterministic computation. Finally, given a value and some non-deterministic computation we can think of the pair as a non-deterministic computation.
Chapter 2

The FIX Logical System

2.1 Review of the Computational Let Calculus

The computational let calculus\(^1\) was introduced by Moggi [Mog89a]. Roughly, it is a formal system which embodies the idea of separating computations from values and is the syntactic analogue of the notion of let category. We make a formal distinction between the elements of a type α and computations of elements of that type; the latter are grouped into a new type Tα. We shall refer to a type of the form Tα as a *computation type*. Moggi's computational let calculus contains the following formation rules:

\[
\begin{array}{c}
\text{α type} \\
Tα \text{ type} \\
M : α \\
\text{Val}(M) : Tα \\
[x : α] \\
E : Tα \\
F(x) : Tβ \\
\text{Let}(E, F) : Tβ
\end{array}
\]

These rules, together with the usual rules for unit type and binary product type constitute the term forming rules for the *computational let calculus*, which we shall denote by ML\(_T\). Intuitively, Val(M) is the value M regarded as a trivial computation which immediately evaluates to itself. The term Let\((E, F)\) denotes the computation which firstly tries to evaluate E to some value M : α and then proceeds to evaluate F(M). These intended meanings are captured by three equational axioms:

\[
\begin{align*}
\text{Let}(\text{Val}(M), F) &= F(M), \\
\text{Let}(E, x.\text{Val}(x)) &= E, \\
\text{Let}(\text{Let}(E, F), G) &= \text{Let}(E, x.\text{Let}(F(x), G)).
\end{align*}
\]

2.2 Extensions of the System ML\(_T\)

The Basic Formal System ML\(_T\)

The reader may be wondering why the most fundamental equational logic which we discuss, namely ML\(_T\), is assumed to contain unit and binary product types along with computation types. When considering practical computational issues, it will be useful to deal with algebraic terms (i.e. terms with a finite number of object level variables). According to the basic principle of categorical semantics (for an

\(^1\)What we are calling the computational let calculus, Moggi refers to as the *computational metalanguage.*
account of this see [Cro90]), we shall need a category with at least finite products to interpret algebraic terms. However, it can be shown [Pit90a] that this is exactly the structure which we need to interpret a unit type and binary product type. Thus it makes little sense to exclude unit and binary product types and terms from the logic; and we gain some uniformity when considering details of the correspondence between the syntax of the logic and corresponding categorical structure.

The Use of $\text{ML}_T$ and its Extensions

At least one of our tasks is to push forward the development of a versatile and general purpose metalogic for semantics of programming and computation languages. We can view the computational let calculus (and its extensions) as a formal metalanguage in which to translate the syntax and rules of other languages; for related work in this area the reader is referred to [Pit90b].

In this thesis we shall consider various extensions of $\text{ML}_T$. What extensions would be worthwhile investigating? At present, we have unit and binary product types, together with computation types. Additionally, some notion of function type will be essential for interpreting functional programming and computation languages. The equational logic $\text{ML}_T$ extended by function types is usually called the computational $\lambda$ calculus and denoted $\lambda\text{ML}_T$. We refer the reader to [Mog89a] and [Pit90b].

Some other fundamental datatypes are natural numbers, booleans and coproducts. As discussed in Chapter 0, we shall introduce a new type called the fixpoint type. It will be interesting to study how the fixpoint type interacts with certain other types. For our purposes it will be convenient to study a calculus which, in addition to the fixpoint type, contains a null type, unit type, binary (co)product types and function type, along with a type of natural numbers. We are aiming to develop a constructive logic for reasoning about programming languages in general and recursive computations in particular: the logic arising from the terms and equations associated with the types just listed provides a good foundation on which to build.

2.3 Fixpoint Objects

We define the notion of a fixpoint object in a suitably structured category. This concept is due to Pitts; see also [CP90a] and [CP90b].

Definition 2.3.1 Given a category $C$ with finite products, the $C$ indexed category $C^{(-)}$ is specified by:

- The objects of $C^{C}$ are those of $C$,
- $C^{C}(A, B) \overset{\text{def}}{=} C(C \times A, B)$ where composition of $g$ and $h$ in $C^{C}$ is $h(\pi, g)$ in $C$,
- $C^{k}(A) \overset{\text{def}}{=} A$ and $C^{k}(g) \overset{\text{def}}{=} g(k \times id)$,

where $k : C' \rightarrow C$ in $C$ and $A \overset{\pi}{\rightarrow} B \overset{h}{\rightarrow} D$ in $C^{C}$. 

20
Note that given a let category $C$ there is an indexed endofunctor $T(-)$ on $C(-)$ where $T^C(A) \overset{\text{def}}{=} TA$ and $T^C(g) \overset{\text{def}}{=} \text{lift}(\eta g)$. With this we make the following definition:

**Definition 2.3.2** In a let category $C$ a *fixpoint object* is specified by the following data

- An initial $T(-)$ algebra whose structure map in the fibre $C^C$ is the morphism $C \times T\Omega \rightarrow T\Omega \rightarrow \Omega$ in $C$. Thus given a morphism $f : TA \rightarrow A$ in $C^C$, there is a unique morphism $i\ell(f) : \Omega \rightarrow A$ in $C^C$ for which the following diagram commutes:

\[
\begin{array}{ccc}
C \times T\Omega & \xrightarrow{id \times \sigma} & C \times \Omega \\
\downarrow^{(\pi_C, \text{lift}(\eta \circ i\ell(f)))} & & \downarrow^{i\ell(f)} \\
C \times TA & \xrightarrow{f} & A
\end{array}
\]

- A global element $\omega : 1 \rightarrow T\Omega$ which gives rise to an equaliser diagram of the form

\[
\begin{array}{ccc}
1 & \xrightarrow{\omega} & T\Omega \\
& & \xrightarrow{\eta \sigma} \\
& & \xrightarrow{id} T\Omega.
\end{array}
\]

The definition of a fixpoint object (which we shall abbreviate to FPO) is reminiscent of a natural numbers object (NNO). Recall that the definition of a NNO in a category with finite products takes a particularly simple form when the ambient category is cartesian closed. Indeed we have the

**Lemma 2.3.3** In a let ccc $C$ a FPO is specified by

- An initial $T$ algebra with structure map $\sigma : T\Omega \rightarrow \Omega$.
- A global element $\omega : 1 \rightarrow T\Omega$ which is the equaliser of $\eta \sigma$ and $id_{T\Omega}$ (exactly as in Definition 2.3.2).

**Proof** See Page 48; we shall use the internal logic of let ccc’s to prove this result. \qed

The usual category-theoretic considerations imply that the structure constituting a FPO is determined uniquely up to isomorphism, within the given let category, by the above properties. One should note also that $\sigma$, being the structure morphism for the initial algebra of an endofunctor, is itself an isomorphism.
Some Examples of Fixpoint Objects

A domain-theoretic example of a let ccc with FPO is the category $\omega Cpo$, whose objects are posets possessing joins of countably infinite chains, and whose morphisms are Scott continuous functions. We will refer to the objects as $\omega cpos$. The operation of adjoining a least element to an $\omega cpo$ $D$ to give the lifted $\omega cpo$

$$D_\bot = \{[d] \mid d \in D\} \cup \{\bot\}$$

gives a strong monad on $\omega Cpo$. There is a FPO in $\omega Cpo$, namely

$$\Omega = \{0 < 1 < \ldots < \top\},$$

which is equipped with structure map $\sigma : \Omega_\bot \to \Omega$ where $\sigma$ is the continuous function

$$\sigma(e) \overset{\text{def}}{=} \begin{cases} 0 & \text{if } e = \bot \\ n + 1 & \text{if } e = [n] \\ \top & \text{if } e = [\top] \end{cases}$$

and $\omega \overset{\text{def}}{=} [\top] \in \Omega_\bot$. Some other monads on $\omega Cpo$ that Moggi [Mog89b] points out as arising in denotational semantics also possess fixpoint objects. For example the exceptions monad $T(D) = (D + E)_\bot$ (with $E$ some fixed discrete $\omega cpo$ of exceptions) and the side-effects monad $T(D) = S \rightarrow (D \times S)_\bot$ (with $S$ some fixed discrete $\omega cpo$ of states) both possess fixpoint objects. We illustrate for the case of the exceptions monad when $E$ is the terminal object $1 \overset{\text{def}}{=} \{*\}$ of $\omega Cpo$. The FPO has an underlying set

$$\Omega \overset{\text{def}}{=} \{\top, (n, a), (n + 1, b) \mid n \in \mathbb{N}\}$$

with order given by $\top$ a top element, $(n, a) \leq (n + 1, b)$, and $(n, a) \leq (n + 1, a)$, along with structure map $\sigma : (\Omega + 1)_\bot \to \Omega$ where $\sigma$ is the continuous function

$$\sigma(e) \overset{\text{def}}{=} \begin{cases} (0, a) & \text{if } e = \bot \\ (1, b) & \text{if } e = \{*\} \\ (n + 1, a) & \text{if } e = [(n, a)] \\ (n + 2, b) & \text{if } e = [(n + 1, b)] \\ \top & \text{if } e = [\top] \end{cases}$$

and $\omega \overset{\text{def}}{=} [\top] \in \Omega_\bot$. This follows from the general theory for solving recursive domain equations over $\omega Cpo$ enriched categories as presented in [SP82]. For suppose that $T$ is an $\omega Cpo$ enriched (strong) monad on $\omega Cpo$ (where $\omega Cpo$ is regarded as a symmetric monoidal category via finite products and is enriched over itself) and that $T$ maps $\omega cpos$ to pointed $\omega cpos$ (i.e. $\omega cpos$ with least elements). To obtain a fixpoint object for such a $T$, one constructs the initial fixed object for $T$ in the category of pointed $\omega cpos$ and embedding-projection pairs by iterating $T$ starting at the one element $\omega cpo$, yielding an isomorphism $\sigma : T(\Omega) \cong \Omega$. Then $(\Omega, \sigma)$ is an initial algebra for $T : \omega Cpo \to \omega Cpo$, and dually $(\Omega, \sigma^{-1})$ is a final coalgebra for that functor: This follows from the limit-colimit coincidence for $\omega Cpo$ enriched categories. The initial algebra property gives us the the first part of the definition of fixpoint object; and Freyd has observed that the second part of Definition 2.3.2 is implied by the coalgebra property. We record this latter observation as a lemma.
Lemma 2.3.4 Given a let ccc, suppose that $\sigma : T\Omega \to \Omega$ is an initial algebra for the functor $T$ (so that in particular, $\sigma$ is an isomorphism). Suppose further that $\sigma^{-1} : \Omega \to T\Omega$ is a final coalgebra for $T$. Then there is a global element $\omega : 1 \to T\Omega$ making $\Omega, \sigma, \omega$ a fixpoint object for $T$.

Proof The final coalgebra property means that for any $g : A \to TA$ there is a unique morphism $\hat{g} : A \to \Omega$ satisfying $\sigma^{-1}\hat{g} = T(\hat{g})g$.

Define $\omega : 1 \to T\Omega$ to be $\sigma^{-1}\eta_1$. From the defining property of $\eta_1$ and the naturality of $\eta$ we get

$$\omega = \sigma^{-1}\eta_1 = T(\eta_1)\eta_1 = \eta_\Omega \eta_1 = (\eta_\Omega \sigma)\omega.$$ 

If $f : A \to T\Omega$ is any other morphism satisfying $f = (\eta_\Omega \sigma)f$, we have to see that $f = \omega$. But from $f = (\eta_\Omega \sigma)f$ and the naturality of $\eta$ one has

$$\sigma^{-1}(\sigma f) = f = \eta_\Omega (\sigma f) = T(\sigma f)\eta A$$

Hence by the uniqueness part of the coalgebra property, $\sigma f = \eta_A$ and thus $f = \sigma^{-1}\eta_A$. The same argument applies equally well with $\omega$ for $f$. Therefore $f = \sigma^{-1}\eta_A = \omega$. $\square$

2.4 The Internal Logic Corresponding to a Fixpoint Object

It is well known that there is a natural correspondence between let categories $C$ and ML$_T$ theories [Mog89b]. Given such a $C$, the corresponding computational let calculus is often referred to as the (equational) internal logic of the category $C$. It is possible to extend the calculus ML$_T$ to capture syntactically the notion of a FPO. This will entail adding a type $\text{fix}$, called the fixpoint type, to ML$_T$ together with certain term forming and equality rules. We present these rules here in an informal natural deduction style:

\[
\begin{align*}
\text{\text{omega}: } T& \text{fix} \\
E : T& \text{fix} \quad \sigma(E) : \text{fix} \\
[x : T\alpha] & \\
F(x) : \alpha & N : \text{fix} \\
\text{lt}_\alpha(F, N) : \alpha & \\
\omega = \text{Val}(\sigma(\omega)) & E = \text{Val}(\sigma(E)) \\
\frac{[x : T\alpha]}{F(x) : \alpha} \quad \frac{E = \omega}{E = \omega} \\
\frac{\text{lt}_\alpha(F, \sigma(E)) = F(\text{Let}(E, n, \text{Val}(\text{lt}_\alpha(F, n))))}{[x : T\alpha]} \\
\frac{[n : \text{fix}]}{G(n) : \alpha} \quad \frac{e : T\text{fix}}{G(\sigma(e)) = F(\text{Let}(e, n, \text{Val}(G(n))))} \\
\frac{}{N : \text{fix}} \\
\frac{}{G(N) = \text{lt}_\alpha(F, N)}
\end{align*}
\]
The type \textit{fix} is so called because in its presence we are always able to form fixpoints of certain terms; correspondingly, in a let category with FPO, we are always guaranteed the existence of fixpoints of certain morphisms. We will leave the precise details until after we have defined a formal system which contains the equational rules for the fixpoint type.

\section{The Equational Logic \textit{FIX}_=}

In Section 2.2 we discussed some appropriate extensions to \textit{ML}_T. The most basic of these was the addition of function types, resulting in the computational \(\lambda\) calculus \(\lambda\textit{ML}_T\). Adding a fixpoint type \textit{fix}, coproduct types \(\alpha + \beta\) and a natural number type \textit{nat} to the computational \(\lambda\) calculus \(\lambda\textit{ML}_T\), we arrive at a system \textit{FIX}_= which extends Gödel's system \(T\) [Gir89]. \textit{FIX}_= admits sound translations of Plotkin's PCF [Plo77] and we shall return to the topic of PCF translations in Chapter 6. We now formally define \textit{FIX}_=.

\textbf{Signatures for \textit{FIX}_=}

\textbf{Definition 2.5.1} A \textit{FIX}_= signature, denoted by \(Sg\), is specified by:

- A collection of \textit{types}. The types are built up in the following way. We are given a collection of \textit{basic ground types}, together with the \textit{distinguished ground types} \textit{unit}, \textit{null}, \textit{nat}, and \textit{fix}. The types are now specified by the following grammar:

\[
\alpha ::= \gamma \mid \alpha \times \alpha \mid \alpha + \alpha \mid \alpha \rightarrow \alpha \mid T\alpha
\]

where \(\gamma\) denotes any ground type.

- A collection of \textit{basic function symbols}, together with the following distinguished function symbols: \(\emptyset\), \((-,-)\), \textit{Fst}, \textit{Snd}, \textit{Inl}_\alpha, \textit{Inr}_\beta, \{\}, \{\}, 

- A \textit{sorting} for each of the basic function symbols, which is a list of \(n + 1\) types and will be written:

\[
f : \alpha_1, \ldots, \alpha_n \rightarrow \alpha_{n+1}.
\]

In the case that \(n\) is zero, we shall write \(f : \alpha\). We say that \(f\) is an \(n\)-ary basic function symbol when its sorting consists of \(n + 1\) types.

Given such a \textit{FIX}_= signature, we define from this an abstract syntax signature \(\Sigma = (\textit{GAr}, \textit{Con})\). The collection of ground arities, \(\textit{GAr}\), is simply the one element set \{\textit{TERM}\}. The collection of constants \(\textit{Con}\) consists of the basic function symbols which have arity \(\textit{TERM}^n \rightarrow \textit{TERM}\) whenever the sorting of \(f\) consists of \(n + 1\) types, a countably infinite set of object level variables which have arity \(\textit{TERM}\), together with the distinguished function symbols. The distinguished function symbols which will represent the simply typed \(\lambda\) calculus, finite products and natural numbers have
their usual arities. The remaining distinguished function symbols have the following arities:

1. $\omega : \text{TERM}$
2. $\{\}, \lnl, \lnr, \text{Val}, \sigma : \text{TERM} \rightarrow \text{TERM}$
3. $\text{Let} : \text{TERM} \rightarrow (\text{TERM} \rightarrow \text{TERM}) \rightarrow \text{TERM}$
4. $\text{lt}_\alpha : (\text{TERM} \rightarrow \text{TERM}) \rightarrow \text{TERM} \rightarrow \text{TERM}$
5. $\{ -, - \} : (\text{TERM} \rightarrow \text{TERM}) \rightarrow (\text{TERM} \rightarrow \text{TERM}) \rightarrow \text{TERM} \rightarrow \text{TERM}$

Associated with a FIX$_\Sigma$ signature is a collection of raw FIX$_\Sigma$ terms. When no confusion can arise we shall refer to these just as raw terms. The raw terms are the closed expressions of the abstract syntax generated from $\Sigma$ with arity \text{TERM}.

**Remark 2.5.2** We make the following abbreviations: Write $FM$ for $\text{App}(F, M)$ and $F^N(M)$ for $\text{ltNat}(F, N, M)$.

### Terms in Context for FIX$_\Sigma$

A context, $\Gamma$, is a finite list of (variable, type) pairs written

$$[x_1: \alpha_1, \ldots, x_n: \alpha_n]$$

where the object level variables $x_1, \ldots, x_n$ are distinct. An empty context will be denoted by white space. We will use the (self explanatory) notation $\Gamma, x: \alpha$ and $\Gamma, \Gamma'$ for the concatenation of contexts, (where of course $x$ does not occur in $\Gamma$) and will write $\Gamma \subseteq \Gamma'$ to mean that $\Gamma$ is a sub-list of $\Gamma'$. We shall write

$$\Gamma \vdash M : \alpha$$

for the judgement that given the context $\Gamma$, the raw FIX$_\Sigma$ term $M$ is well formed and has type $\alpha$. In such cases the raw term $M$ will be referred to as a FIX$_\Sigma$ term in context. These judgements are generated by the following rules:

<table>
<thead>
<tr>
<th>Variables</th>
</tr>
</thead>
<tbody>
<tr>
<td>$\Gamma, x: \alpha, \Gamma' \vdash x: \alpha$</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Basic Function Symbols</th>
</tr>
</thead>
<tbody>
<tr>
<td>$\Gamma \vdash M_1: \alpha_1, \ldots, M_n: \alpha_n$</td>
</tr>
<tr>
<td>$\Gamma \vdash f(M_1, \ldots, M_n): \alpha$</td>
</tr>
</tbody>
</table>

where $f$ is any function symbol with sorting $f: \alpha_1, \ldots, \alpha_n \rightarrow \alpha$
## Unit Terms

\[ \Gamma \vdash \emptyset : \text{unit} \]

## Null Terms

\[ \Gamma \vdash M : \text{null} \]
\[ \Gamma \vdash \{\} _{\alpha}(M) : \alpha \]

## Binary Product Terms

\[ \Gamma \vdash M : \alpha \quad \Gamma \vdash N : \beta \]
\[ \Gamma \vdash (M, N) : \alpha \times \beta \]
\[ \Gamma \vdash P : \alpha \times \beta \]
\[ \Gamma \vdash \text{Fst}(P) : \alpha \]
\[ \Gamma \vdash \text{Snd}(P) : \beta \]

## Binary Coproduct Terms

\[ \Gamma \vdash M : \alpha \]
\[ \Gamma \vdash N : \beta \]
\[ \Gamma \vdash \text{Inl}_\alpha(M) : \alpha + \beta \]
\[ \Gamma \vdash \text{Inr}_\alpha(N) : \alpha + \beta \]
\[ \Gamma, x : \alpha \vdash F(x) : \gamma \]
\[ \Gamma, y : \beta \vdash G(y) : \gamma \]
\[ \Gamma \vdash C : \alpha + \beta \]
\[ \Gamma \vdash \{F, G\}(C) : \gamma \]

## Function Terms

\[ \Gamma, x : \alpha \vdash F(x) : \beta \]
\[ \Gamma \vdash \lambda_\alpha(F) : \alpha \rightarrow \beta \]
\[ \Gamma \vdash F \rightarrow \alpha \beta \]
\[ \Gamma \vdash FM : \beta \]

## Computation Terms

\[ \Gamma \vdash M : \alpha \]
\[ \Gamma \vdash E : T\alpha \]
\[ \Gamma, x : \alpha \vdash F(x) : T\beta \]
\[ \Gamma \vdash \text{Val}(M) : T\alpha \]
\[ \Gamma \vdash \text{Let}(E, F) : T\beta \]

## Natural Number Terms

\[ \Gamma \vdash 0 : \text{nat} \]
\[ \Gamma \vdash \text{Suc}(M) : \text{nat} \]
\[ \Gamma \vdash M : \alpha \]
\[ \Gamma, x : \alpha \vdash F(x) : \alpha \]
\[ \Gamma \vdash N : \text{nat} \]
\[ \Gamma \vdash F^N(M) : \alpha \]

## Fixpoint Terms

\[ \Gamma \vdash \omega : T\text{fix} \]
\[ \Gamma \vdash E : T\text{fix} \]
\[ \Gamma, x : T\alpha \vdash F(x) : \alpha \]
\[ \Gamma \vdash N : \text{fix} \]
\[ \Gamma \vdash \sigma(E) : \text{fix} \]
\[ \Gamma \vdash \text{lt}_\alpha(F, N) : \alpha \]

### Remark 2.5.3
The usual rules for weakening of contexts, and substitution of raw terms for object level variables, are derivable from the above rules by simple structural induction.
Equational Theories for $\text{FIX}_=$

A $\text{FIX}_=$ equation in context takes the form

$$\Gamma \vdash M = M': \alpha$$

where $M, M'$ are raw $\text{FIX}_=$ terms satisfying $\Gamma \vdash M: \alpha$ and $\Gamma \vdash M': \alpha$. A $\text{FIX}_=$ theory, $Th$, is specified by a $\text{FIX}_=$ signature, together with a specific collection of equations in context, which are called the axioms of $Th$. The collection of theorems of $Th$ is the least collection of equations in context which contains the axioms of $Th$, and is closed under the following rules:

### Function Symbol Congruence

Every function symbol is required to be a congruence

### Weakening

$$\Gamma \vdash M = M': \alpha \quad \text{where} \quad \Gamma \subseteq \Gamma'.$$

### Equational Logic

$$\begin{align*}
\Gamma \vdash M: \alpha & \quad \text{and} \quad \Gamma \vdash M = M': \alpha \\
\Gamma \vdash M' = M: \alpha & \quad \text{and} \quad \Gamma \vdash M' = M': \alpha \\
\Gamma \vdash M = M': \alpha & \quad \text{and} \quad \Gamma \vdash M' = M': \alpha
\end{align*}$$

### Unit Equations

$$\Gamma \vdash M: \text{unit} \quad \Gamma \vdash M = \{\}_\alpha: \text{unit}$$

### Null Equations

$$\Gamma, x: \text{null} \vdash F(x): \alpha \quad \Gamma \vdash M: \text{null} \quad \Gamma \vdash F(M) = \{\}_\alpha(M): \alpha$$

### Binary Product Equations

$$\begin{align*}
\Gamma \vdash M: \alpha & \quad \Gamma \vdash N: \beta \\
\Gamma \vdash \text{Fst}(M, N) = M: \alpha \\
\Gamma \vdash \text{Snd}(M, N) = N: \beta
\end{align*}$$

$$\Gamma \vdash P: \alpha \times \beta \quad \Gamma \vdash \langle \text{Fst}(P), \text{Snd}(P) \rangle = P: \alpha \times \beta$$

27
**Binary Coproduct Equations**

\[
\begin{align*}
\Gamma, x: \alpha & \vdash F(x) : \gamma & \Gamma, y: \beta & \vdash G(y) : \gamma & \Gamma \vdash M : \alpha \\
\Gamma & \vdash \{F, G\}(\text{inl}_\beta(M)) = F(M) : \gamma \\
\Gamma, x: \alpha & \vdash F(x) : \gamma & \Gamma, y: \beta & \vdash G(y) : \gamma & \Gamma \vdash N : \beta \\
\Gamma & \vdash \{F, G\}(\text{inr}_\alpha(N)) = G(N) : \gamma \\
\Gamma, z: \alpha + \beta & \vdash H(z) : \gamma & \Gamma \vdash C : \alpha + \beta \\
\Gamma & \vdash \{u. H(\text{inl}_\beta(u)), v. H(\text{inr}_\alpha(v))\}(C) = H(C) : \gamma
\end{align*}
\]

**Function Equations**

\[
\begin{align*}
\Gamma, x: \alpha & \vdash F(x) : \beta & \Gamma \vdash M : \alpha & & \Gamma \vdash M : \alpha \to \beta \\
\Gamma \vdash \lambda_\alpha(F) M = F(M) : \beta & & \Gamma \vdash \lambda_\alpha(u. M u) = M : \alpha \to \beta
\end{align*}
\]

**Computation Equations**

\[
\begin{align*}
\Gamma & \vdash M : \alpha & \Gamma, x: \alpha & \vdash F(x) : T \beta & \Gamma \vdash E : T \alpha \\
\Gamma \vdash \text{let}\ (\text{Val}(M), F) = F(M) : T \beta & & \Gamma \vdash \text{let}\ (E, x. \text{Val}(x)) = E : T \alpha \\
\Gamma \vdash E : T \alpha & & \Gamma, x: \alpha & \vdash F(x) : T \beta & \Gamma, y: \beta & \vdash G(y) : T \gamma \\
\Gamma \vdash \text{let}\ (E, F, G) = \text{let}\ (E, u. \text{let}\ (F(u), G)) : T \gamma
\end{align*}
\]

**Mono Condition**

\[
\begin{align*}
\Gamma & \vdash \text{Val}(M) = \text{Val}(M') : T \alpha \\
\Gamma \vdash M = M' : \alpha
\end{align*}
\]

**Natural Number Equations**

\[
\begin{align*}
\Gamma & \vdash M : \alpha & \Gamma, x: \alpha & \vdash F(x) : \alpha \\
\Gamma & \vdash F^\alpha(M) = M : \alpha \\
\Gamma & \vdash M : \alpha & \Gamma, x: \alpha & \vdash F(x) : \alpha & \Gamma \vdash N : \text{nat} \\
\Gamma & \vdash F^{\text{Suc}(N)}(M) = F(F^N(M)) : \alpha
\end{align*}
\]

\[
\begin{align*}
\{ \Gamma \vdash N : \text{nat} & & \Gamma \vdash G(0) = M : \alpha \\
\Gamma, x: \alpha & \vdash F(x) : \alpha & \Gamma, n: \text{nat} & \vdash G(\text{Suc}(n)) = F(G(n)) : \text{nat} & \Gamma, n: \text{nat} & \vdash G(n) : \alpha \\
\Gamma \vdash G(n) = F^N(M) : \alpha
\} \end{align*}
\]

**Fixpoint Equations**

\[
\begin{align*}
\Gamma & \vdash \omega = \text{Val}(\sigma(\omega)) : T \text{fix} & \Gamma \vdash E = \text{Val}(\sigma(E)) : T \text{fix} \\
\Gamma, x: T \alpha & \vdash F(x) : \alpha & \Gamma \vdash E : T \text{fix} \\
\Gamma \vdash \text{let}_\alpha(F, \sigma(E)) = F(\text{let}(E, n. \text{Val}(\text{let}_\alpha(F, n)))) : \alpha \\
\{ \Gamma \vdash N : \text{fix} & & \Gamma, x: T \alpha & \vdash F(x) : \alpha \\
\Gamma, e: T \text{fix} & \vdash G(\sigma(e)) = F(\text{let}(e, n. \text{Val}(G(n)))) : \alpha & \Gamma, n: \text{fix} & \vdash G(n) : \alpha \\
\Gamma \vdash G(N) = \text{let}_\alpha(F, N) : \alpha
\} \end{align*}
\]

28
The usual rule for substitution is derivable from the above rules. More precisely we have

**Lemma 2.5.4** The rule

\[
\Gamma, x: \alpha \vdash N(x) = N'(x): \beta \quad \Gamma \vdash M = M': \alpha
\]

\[
\Gamma \vdash N(M) = N'(M'): \beta
\]

is derivable from the rules given on Page 27.

**Proof** Use Function Symbol Congruence to deduce \( \Gamma \vdash \lambda_\alpha(N) M = \lambda_\alpha(N') M': \beta \).

The result follows. \( \square \)

**Remark 2.5.5** The Mono Condition is the syntactic requirement which captures the idea that values may be trivially regarded as computations which evaluate immediately to themselves. Note also that there are no side conditions on any of the extensionality rules due to the fact that object level variables are regarded as constants in the meta \( \lambda \) calculus.
Chapter 3

Categorical Semantics of the $\text{FIX}_=\text{Logic}$

3.1 FIX Categories

**Definition 3.1.1** A $\text{FIX category}$ is a set $\text{ccc}$ which is endowed with finite co-products, $\text{FPO}$, $\text{NNO}$ and for which the components of the unit of the monad are monics.

Imposing the condition that the unit components are monic captures semantically the idea that a value may be trivially regarded as a computation. Note also that to specify a FIX category we take a fixed choice of strong monad.

The syntax of $\text{FIX}_=$, in particular Null and Binary Coproduct Terms and Equations, will be interpreted in FIX categories. In order to interpret such syntax soundly, the FIX category must have stable finite coproducts i.e. the functor $C \times (-)$ must preserve finite coproducts. This is automatic: any FIX category is cartesian closed and so $C \times (-)$ has a right adjoint.

**Definition 3.1.2** A FIX category morphism $F: C \to D$ is a monad morphism $(F, i)$ between the underlying monads for which $F$ preserves the categorical structure up to isomorphism, and each $i$ is a natural isomorphism.

**Remark 3.1.3** Note that the operation on objects $A \mapsto TA$ is not a categorical property of the FIX category; as noted above there is a fixed choice of strong monad. Thus to be given a FIX category morphism $F: (C, T) \to (D, S)$ means for each object $A$ in $C$ we are given an isomorphism $i_A: FTA \cong SFA$ which is compatible with the remaining structure. For example, suppose we are given a morphism $f: A \times B \to TC$ in $C$. Then there is a morphism $g: F(A \times FB) \cong F(A \times B) F_1, FTC \to SFC$ and a morphism $h: F(A \times FTB) \cong F(A \times TB) F(i_{FTC}) FTC$ for which, by definition, the following diagram commutes:

\[
\begin{array}{ccc}
FA \times SFB & \xrightarrow{\text{lift}(g)} & SFC \\
id \times i_B & & \downarrow i_C \\
FA \times FTB & \xrightarrow{h} & FTC
\end{array}
\]
The (categorical) isomorphisms are, of course, the canonical ones, arising from
the categorical property of "having (specified) binary products" together with the
definition of finite product preserving functor.

An example of such a FIX category is $\omega Cpo$. Note that the forgetful functor from
$\omega Cpo$ to $Set$ reflects monics.

3.2 Categorical Semantics of $\text{FIX}_-$

Structures for $\text{FIX}_-$ Signatures

Let $Sg$ be a $\text{FIX}_-$ signature. A structure, $M$, in a FIX category $C$ is specified by
the following data:

- An object $\llbracket \gamma \rrbracket$ for each basic ground type $\gamma$ of $Sg$, and
- for each basic function symbol $f: \alpha_1, \ldots, \alpha_n \to \alpha$, a morphism in $C$ of the form

  $\llbracket f \rrbracket : \llbracket \alpha_1 \rrbracket \times \ldots \times \llbracket \alpha_n \rrbracket \to \llbracket \alpha \rrbracket$.

Interpretation of the $\text{FIX}_-$ Types

Given a structure $M$ we shall now show how to interpret the syntax of $\text{FIX}_-$ in
a FIX category $C$. The types are interpreted as objects in the category, where the
interpretation of a type $\alpha$ is denoted by $\llbracket \alpha \rrbracket$. We make the following definition

Definition 3.2.1 The interpretation of a type $\alpha$ is given by:

- $\llbracket \text{unit} \rrbracket \overset{\text{def}}{=} 1$ where $1$ is the terminal object.
- $\llbracket \text{null} \rrbracket \overset{\text{def}}{=} 0$ where $0$ is the initial object.
- $\llbracket \text{nat} \rrbracket \overset{\text{def}}{=} N$ where $N$ is the NNO.
- $\llbracket \text{fix} \rrbracket \overset{\text{def}}{=} \Omega$ where $\Omega$ is the FPO.
- $\llbracket \alpha \times \beta \rrbracket \overset{\text{def}}{=} \llbracket \alpha \rrbracket \times \llbracket \beta \rrbracket$.
- $\llbracket \alpha + \beta \rrbracket \overset{\text{def}}{=} \llbracket \alpha \rrbracket + \llbracket \beta \rrbracket$.
- $\llbracket \alpha \to \beta \rrbracket \overset{\text{def}}{=} \llbracket \alpha \rrbracket \to \llbracket \beta \rrbracket$.
- $\llbracket T \alpha \rrbracket \overset{\text{def}}{=} T \llbracket \alpha \rrbracket$. 

32
Interpretation of the FIX= Terms in Context

Given a context $\Gamma = [x_1: \alpha_1, \ldots, x_n: \alpha_n]$ let $\llbracket \Gamma \rrbracket \overset{\text{def}}{=} [\alpha_1] \times \ldots \times [\alpha_n]$. Then for each context $\Gamma$, raw term $M$ and type $\alpha$ for which $\Gamma \vdash M: \alpha$ is a valid judgement, we interpret this by giving a morphism

$$\llbracket \Gamma \vdash M: \alpha \rrbracket : [\Gamma] \rightarrow [\alpha].$$

Note that when $\Gamma \vdash M: \alpha$ is a valid judgement, because the type $\alpha$ is uniquely determined by $M$ and $\Gamma$, we will abbreviate $\llbracket \Gamma \vdash M: \alpha \rrbracket$ to just $\llbracket \Gamma.M \rrbracket$, and to $\llbracket M \rrbracket$ if $\Gamma$ is empty.

**Definition 3.2.2** The semantics of terms in context is defined by a structural induction on terms:

- $\llbracket \Gamma, x: \alpha, \Gamma.*x \rrbracket \overset{\text{def}}{=} \pi : [\Gamma] \times [\alpha] \times [\Gamma.\alpha] \rightarrow [\alpha]$.
- Let $f: \alpha_1, \ldots, \alpha_n \rightarrow \alpha$ be a basic function symbol; then $\llbracket \Gamma.f(M_1, \ldots, M_n) \rrbracket \overset{\text{def}}{=} \llbracket f \rrbracket ([\Gamma.M]) : [\Gamma] \rightarrow [\alpha_1] \times \ldots \times [\alpha_n] \rightarrow [\alpha]$.
- $\llbracket \Gamma.\bot \rrbracket \overset{\text{def}}{=} [\Gamma] \rightarrow 1$.
- $\llbracket \Gamma.\{}(M) \rrbracket \overset{\text{def}}{=} \llbracket \Gamma.M \rrbracket : [\Gamma] \rightarrow 0 \rightarrow [\alpha]$.
- $\llbracket \Gamma.(N) \rrbracket \overset{\text{def}}{=} \llbracket \Gamma.M \rrbracket : [\Gamma] \rightarrow [\alpha] \times [\beta]$.
- $\llbracket \Gamma.F(P) \rrbracket \overset{\text{def}}{=} \pi \llbracket \Gamma.P \rrbracket : [\Gamma] \rightarrow [\alpha] \times [\beta] \rightarrow [\alpha]$.
- $\llbracket \Gamma.Snd(P) \rrbracket \overset{\text{def}}{=} \pi \llbracket \Gamma.P \rrbracket : [\Gamma] \rightarrow [\alpha] \times [\beta] \rightarrow [\beta]$.
- $\llbracket \Gamma.(F, G)(C) \rrbracket \overset{\text{def}}{=} \{ \llbracket \Gamma, x: \alpha.F(x) \rrbracket, \llbracket \Gamma, y: \beta.G(y) \rrbracket \} \langle \text{id}, [\Gamma.C] \rangle$ : $[\Gamma] \rightarrow [\Gamma] \times ([\alpha] + [\beta]) \rightarrow [\gamma]$.
- $\llbracket \Gamma.I_{\beta}(M) \rrbracket \overset{\text{def}}{=} \iota \llbracket \Gamma.M \rrbracket : [\Gamma] \rightarrow [\alpha] \rightarrow [\alpha] + [\beta]$.
- $\llbracket \Gamma.I_{\alpha}(N) \rrbracket \overset{\text{def}}{=} \jmath \llbracket \Gamma.N \rrbracket : [\Gamma] \rightarrow [\beta] \rightarrow [\alpha] + [\beta]$.
- $\llbracket \Gamma.(F : \alpha) \rrbracket \overset{\text{def}}{=} \text{cur}([\Gamma, x: \alpha.F(x)] : [\Gamma] \rightarrow ([\alpha] 
\text{→} [\beta])$.
- $\llbracket \Gamma.F.M \rrbracket \overset{\text{def}}{=} \text{ap}([\Gamma.F], [\Gamma.M]) : [\Gamma] \rightarrow ([\alpha] \rightarrow [\beta]) \times [\alpha] \rightarrow [\beta]$.
- $\llbracket \Gamma.\text{Val}(M) \rrbracket \overset{\text{def}}{=} \eta \llbracket \Gamma.M \rrbracket : [\Gamma] \rightarrow [\alpha] \rightarrow T[\alpha]$.
- $\llbracket \Gamma.F.P \rrbracket \overset{\text{def}}{=} \text{lift}([\Gamma, x: \alpha.F(x)] \langle \text{id}, [\Gamma.E] \rangle : [\Gamma] \rightarrow [\Gamma] \times T[\alpha] \rightarrow T[\beta]$.
- $\llbracket \Gamma.O \rrbracket \overset{\text{def}}{=} \text{0!} : [\Gamma] \rightarrow 1 \rightarrow N$.
- $\llbracket \Gamma.Suc(N) \rrbracket \overset{\text{def}}{=} \text{s}([\Gamma.N] : [\Gamma] \rightarrow N \rightarrow N)$.
• \([\Gamma . F^N(M)] \stackrel{\text{def}}{=} h(id, [\Gamma . N]): [\Gamma] \to [\Gamma] \times N \to [\alpha]\)

where \(h\) is the unique morphism arising from the universal property of the NNO together with the morphism

\([\Gamma, x: \alpha.F(x)](id, [\Gamma . M]): [\Gamma] \to [\Gamma] \times [\alpha] \to [\alpha].\]

• \([\Gamma . \omega] \stackrel{\text{def}}{=} \omega!: [\Gamma] \to 1 \to T\Omega.\]

• \([\Gamma . \sigma(E)] \stackrel{\text{def}}{=} \sigma\circ [\Gamma . E]: [\Gamma] \to T\Omega \to \Omega.\]

• \([\Gamma . \lambda\alpha(F, N)] \stackrel{\text{def}}{=} h(id, [\Gamma . N]): [\Gamma] \to [\Gamma] \times \Omega \to [\alpha]\)

where \(h\) is the unique morphism arising from the universal property of the FPO together with the morphism

\([\Gamma, x:T\alpha.F(x)](id, [\Gamma] \times T[\alpha] \to [\alpha].\]

This completes the definition of the categorical interpretations of the terms in context.

Models of \(\text{FIX}_\omega\) Theories

A structure \(M\) in \(\mathcal{C}\) for a signature \(Sg\) satisfies an equation in context \(\Gamma \vdash M = M' : \alpha\) if \([\Gamma . M]\) and \([\Gamma . M']\) are equal morphisms in \(\mathcal{C}\). Given a \(\text{FIX}_\omega\) theory, \(Th\), then \(M\) is called a model of the \(\text{FIX}_\omega\) theory if it satisfies all of the axioms of \(Th\).

The Substitution Lemma

Lemma 3.2.3 The categorical semantics interprets the substitution of a term for a variable in a term via composition in the category. More precisely, if \(\Gamma \vdash M_i : \alpha_i\) for \(i = 1, \ldots, n\) and also \(\Gamma' \vdash N(x_1, \ldots, x_n) : \beta\) where \(\Gamma' = [x_1 : \alpha_1, \ldots, x_n : \alpha_n]\), we have

\([\Gamma . N(M)] = [\Gamma' . N(x)] \circ ([\Gamma . M_1], \ldots, [\Gamma . M_n]).\)

Proof The proof is a routine induction on the structure of \(N\). Note that in Section 3.3 we shall investigate the most general interpretation of the syntax of a \(\text{FIX}_\omega\) theory subject to the requirement that substitution of syntax is modelled by composition of morphisms; this, in essence, supplies the details of the proof for terms \(N\) of computation or fixpoint type. \(\square\)

The Soundness Theorem

The most important property of models \(M\) of \(\text{FIX}_\omega\) theories is that any theorem of a theory must be satisfied by \(M\). Indeed we have the

34
Theorem 3.2.4 ["FIX∞ Soundness"] Let \( C \) be a FIX category, \( Th \) a FIX∞ theory, and \( M \) a model of \( Th \) in \( C \). Then \( M \) satisfies any equation in context which is a theorem of \( Th \).

Proof We have to check that the rules for deriving equations in context are closed with respect to satisfaction by \( M \). The details are omitted. \( \square \)

3.3 Interpretations of Computation Types and the Fixpoint Type

The interpretation of most of the syntax of a FIX∞ theory is perfectly standard and well understood. However, the interpretation of computation types and the fixpoint type is relatively new. Thus we shall show that our interpretations are the most general we could hope for, given the proviso that substitution of terms in the syntax is to be modelled by composition of morphisms in the category theory. Let us suppose that we are given a FIX∞ signature \( Sg \) and a FIX category \( C \).

Modelling the Types

The interpretation of the computation types \( T\alpha \) is forced. As noted on Page 31, the operation \( A \mapsto TA \) is not a categorical property of the FIX category, but is specified as part of the definition. Thus we interpret the type \( T\alpha \) by the object \( \llbracket T\alpha \rrbracket \overset{\text{def}}{=} T\llbracket \alpha \rrbracket \). As for the type \( fix \), we shall, for the time being, interpret it as an undefined object \( \Omega \).

Modelling Terms in Context of Computation Type

Consider the rules

\[
\frac{\Gamma \vdash M : \alpha}{\Gamma \vdash \text{Val}(M) : T\alpha} \quad \frac{\Gamma \vdash E : T\alpha \quad \Gamma, x : \alpha \vdash F(x) : T\beta}{\Gamma \vdash \text{let}(E, F) : T\beta}
\]

In the syntax, substitution must commute with term formation. We model substitution of terms, in the syntax, via composition of the interpreting morphisms in the category \( C \). Thus, to interpret the first rule, we need a natural transformation

\[ \theta : C(-, A) \rightarrow C(-, TA). \]

Using the Yoneda Lemma, we have a bijection

\[ [C^{op}, Set](C(-, A), C(-, TA)) \cong C(A, TA), \]

and in particular the action of the components \( \theta_C \) arise by post-composition with a morphism \( f : A \rightarrow TA \). By definition, this morphism \( f \) will be \( \eta_A \). To summarise,

\[ \llbracket \Gamma. \text{Val}(M) : T\alpha \rrbracket \overset{\text{def}}{=} \eta_{\llbracket M \rrbracket}[\Gamma.M]. \]

35
Similarly, to interpret the second rule, we shall need a natural transformation which has components

$$\theta_C: C(C, TA) \times C(C \times A, TB) \to C(C, TB).$$

If we apply naturality to a morphism $\langle id, g \rangle: C \to C \times TA$ we find that

$$\theta(g, f) = \theta(\pi_2, f(\pi_1 \times id_A))(id, g)$$

where $\pi_1: C \times TA \to C$ and $\pi_2: C \times TA \to TA$. Thus we can soundly interpret the second rule with a natural transformation which has components

$$\theta_C: C(C \times A, TB) \to C(C \times TA, TB).$$

Given a morphism $f: C \times A \to TB$ we shall denote the effect of the components of $\theta$ by $f \mapsto f^*$. Combining our results, we are led to the following definition

$$\langle \Gamma \vdash \text{Let}(E, F) \rangle \overset{\text{def}}{=} f^*(id, e),$$

where by structural induction we already have

$$\langle \Gamma, x: \alpha. F(x) \rangle = f$$

$$\langle \Gamma. E \rangle = e.$$

### Modelling Equations in Context of Computation Type

**Proposition 3.3.1** In order to soundly model the computation type equations we need exactly the structure of a let category.

**Proof** Recall Definition 1.3.1. We established above the necessity of the existence of the function

$$(-)^*: C(C \times A, TB) \to C(C \times TA, TB)$$

which is natural in $C$. This amounts to asking that

$$(f(g \times id))^* = f^*(g \times id)$$

where $f: C \times A \to TB$ and $g: C' \to C$. This is precisely LiftS.

The computation type equations are

1. $\Gamma \vdash \text{Let}(\text{Val}(M), F) = F(M)$ (3.1)
2. $\Gamma \vdash \text{Let}(E, u. \text{Val}(u)) = E$ (3.2)
3. $\Gamma \vdash \text{Let}(\text{Let}(E, F), G) = \text{Let}(E, u. \text{Let}(F(u), G))$ (3.3)

Working through the details, in order to soundly interpret equation 3.1 we need

$$f^*(id \times \eta)(id, m) = f(id, m)$$

(3.4)
where \( f: C \times A \to TB \) and \( m: C \to A \). For this, it is clearly sufficient to ask that \( \text{LiftB} \) holds. For necessity, take

\[
\pi_1: C \times A \to A \quad \pi_2: C \times A \to C.
\]

Then we have

\[
f = f(\pi_2 \times id)(id, \pi_1)
\]

using an instance of 3.4

\[
(\pi_2 \times id)(id \times \eta)(id, \pi_1)
\]

using naturality of \((-)^* \)

\[
f^*(\pi_2 \times id)(id \times \eta)(id, \pi_1)
\]

\[
f^*(id \times \eta).
\]

In order to soundly interpret equation 3.2 we need

\[
(\eta \pi_1)^*(id, e) = e \tag{3.5}
\]

where \( e: C \to TA \) and \( \pi_1: C \times A \to A \). It is sufficient for \( \text{LiftH} \) to hold. For necessity, take

\[
\pi_2: C \times TA \to TA \quad \pi_3: C \times TA \to C
\]

\[
\pi_4: (C \times TA) \times A \to A.
\]

Then we have

\[
(\eta \pi_1)^* = (\eta \pi_1)^*(\pi_3 \times id)(id, \pi_2)
\]

from naturality of \((-)^* \)

\[
(\eta \pi_1^{\pi_3}(\pi_3 \times id))^*(id, \pi_2)
\]

\[
(\eta \pi_4)^*(id, \pi_2)
\]

using an instance of 3.5

\[
\pi_2
\]

as required.

Finally, in order to model equation 3.3 soundly, we need to ask that

\[
g^*(id \times f^*)(id, \langle id, e \rangle) = ((g(\pi_1 \times id))^*(id, f))^*(id, e) \tag{3.6}
\]

where

\[
\pi_1: C \times A \to C \quad f: C \times A \to TB
\]

\[
g: C \times B \to TB \quad e: C \to TA.
\]

Now consider the projection morphisms

\[
\pi_2: C \times TA \to C \quad \pi_3: C \times TA \to TA
\]

\[
\pi_4: (C \times TA) \times A \to (C \times TA).
\]

Using naturality of \((-)^* \) the equation 3.6 becomes

\[
g^*(id \times f^*)(id, \langle id, e \rangle) = (g^*(\pi_1, f))^*(id, e). \tag{3.7}
\]
It is certainly sufficient for equation $\text{Lift}_{\text{A}}$ to hold. Indeed, it is also necessary, as we now show:

\[
(g^*(\pi_1, f))^* = (g^*(\pi_1, f))^*(\pi_2 \times id)(id, \pi_3)
\]

using naturality of $(-)^*$

\[
=(g^*(\pi_1, f)(\pi_2 \times id))^*(id, \pi_3)
\]

\[
= (g^*(\pi_2 \pi_4, f(\pi_2 \times id)))^*(id, \pi_3)
\]

\[
= ((g(\pi_2 \times id))^*\langle \pi_4, f(\pi_2 \times id)\rangle)^*(id, \pi_3)
\]

using equation 3.7

\[
= (g(\pi_2 \times id))^*(id \times (f(\pi_2 \times id))^*)(id, \langle id, \pi_3 \rangle)
\]

\[
= g^*(id \times f^*)(\pi_2 \times (\pi_2 \times id))(id, \langle id, \pi_3 \rangle)
\]

\[
= g^*(\pi_2, f^*).
\]

\[
\square
\]

**Modelling Terms in Context of Fixpoint Type**

Consider the rules

\[
\Gamma \vdash \omega : T_{\text{fix}} \quad \Gamma \vdash E : T_{\text{fix}} \quad \Gamma, x : T \alpha \vdash F(x) : \alpha \quad \Gamma \vdash N : \text{fix}
\]

\[
\Gamma \vdash \sigma(E) : \text{fix}
\]

\[
\Gamma \vdash \text{lt}_{\alpha}(F, N) : \alpha
\]

To interpret the first rule, we shall need a global element of $T\Omega$. (Remember that for the time being, $\Omega$ is just some arbitrary object of a let category). So we have

\[
[[\Gamma.\omega]] \overset{\text{def}}{=} \omega : [[\Gamma]] \rightarrow 1 \rightarrow T\Omega.
\]

To interpret the second rule, with the usual assumptions about the way we shall model substitution, we shall need a natural transformation

\[
\theta : \mathcal{C}(-, T\Omega) \rightarrow \mathcal{C}(-, \Omega).
\]

Using the Yoneda Lemma, the effect of the components $\theta_C$ arise by post-composition with a morphism $\sigma : T\Omega \rightarrow \Omega$. Thus we have

\[
[[\Gamma.\sigma(E)]] \overset{\text{def}}{=} \sigma e,
\]

where, by structural induction we already have $[[\Gamma.E]] = e$.

To interpret the third rule, we shall need a natural transformation with components

\[
\theta_C : \mathcal{C}(C \times T\alpha, A) \times \mathcal{C}(C, \Omega) \rightarrow \mathcal{C}(C, A)
\]

Applying naturality to $\langle \text{id}, n \rangle : C \rightarrow C \times \Omega$, we get

\[
\theta(f, n) = \theta(f(\pi_1 \times id), \pi_2)(\text{id}, n)
\]

where $\pi_1 : C \times \Omega \rightarrow C$ and $\pi_2 : C \times \Omega \rightarrow \Omega$. Thus we can soundly model the third rule with a natural transformation which has components

\[
\theta_C : \mathcal{C}(C \times T\alpha, A) \rightarrow \mathcal{C}(C \times \Omega, A),
\]

38
and we shall write $f \mapsto f^*$ for the effect of this function. Thus we are led to setting

$$\llbracket \Gamma.\text{lt}(F, N) \rrbracket \overset{\text{def}}{=} f^*(\text{id}, n),$$

where we already have

$$\llbracket \Gamma, x : T \alpha. F(x) \rrbracket = f$$

$$\llbracket \Gamma. N \rrbracket = n.$$

### Modelling Equations in Context of Fixpoint Type

**Proposition 3.3.2** In order to soundly model the fixpoint type equations, we shall need exactly a let category $C$ which is endowed with a FPO.

**Proof** The fixpoint type equations are

$$\Gamma \vdash \omega = \text{Val}(\sigma(\omega)) \quad (3.8)$$

$$\Gamma \vdash E = \text{Val}(\sigma(E)) \supset \Gamma \vdash E = \omega \quad (3.9)$$

$$\Gamma, e \vdash G(\sigma(e)) = F(\text{Let}(e, n.\text{Val}(G(n)))) \supset \Gamma \vdash G(N) = \text{lt}_\alpha(F, N) \quad (3.10)$$

$$\Gamma \vdash \text{lt}_\alpha(F, \sigma(E)) = F(\text{Let}(E, n.\text{Val}(\text{lt}_\alpha(F, n)))) \quad (3.11)$$

It is easy to see that for the sound modelling of 3.8 and 3.9 it is necessary and sufficient that the triple $(\omega, \sigma, \Omega)$ forms part of the equaliser diagram of Definition 2.3.2 of a FPO.

Note that in the FIX logic, (modulo rules for which we have soundness), rule 3.10 is equivalent to

$$\Gamma, e \vdash G(\sigma(e)) = F(\text{Let}(e, n.\text{Val}(G(n)))) \supset \Gamma, n \vdash G(n) = \text{lt}_\alpha(F, n) \quad (3.12)$$

In order to soundly model 3.12 we see it is necessary that

$$\frac{g(\text{id} \times \sigma) = f(\pi_1, \text{lift}(\eta g))}{g = f^* \quad (\ast)}$$

where $f : C \times TA \to A$, $g : C \times \Omega \to A$ and $\pi_1 : C \times T\Omega \to C$; sufficiency of the uniqueness requirement of a FPO is immediate.

Finally, we look at the structure needed to soundly model 3.11. Put

$$\pi_2 : C \times T\Omega \to T\Omega \quad \pi_3 : C \times \Omega \to C \quad \pi_4 : C \times \Omega \to \Omega.$$

Working through the details we shall need

$$f^*(\text{id} \times \sigma)(\text{id}, e) = f(\text{id}, \text{lift}(\eta f(\pi_3 \times \text{id}))(\pi_4)(\text{id}, e)) \quad (3.13)$$

where $e : C \to T\Omega$. However, we can appeal to $(\ast)$ to deduce that $(f(\pi_3 \times \text{id}))^* = f^*(\pi_3 \times \text{id})$; thus 3.13 reduces to

$$f^*(\text{id} \times \sigma)(\text{id}, e) = f(\text{id}, \text{lift}(\eta f^*)(\text{id}, e)). \quad (3.14)$$
The universal property of a FPO is certainly sufficient to ensure that 3.14 holds. To see that it is also necessary, note that

\[
f(\pi_1, \text{lift}(\eta f^*)) = f(\pi_1 \times \text{id}, \text{lift}(\eta f^*(\pi_1 \times \text{id}))(\text{id}, \pi_2)) \\
= f(\pi_1 \times \text{id}, \text{lift}(\eta(f(\pi_1 \times \text{id}))^*)(\text{id}, \pi_2))
\]

using an instance of 3.14

\[
= (f(\pi_1 \times \text{id}))^*(\text{id} \times \sigma)(\text{id}, \pi_2) \\
= f^*(\pi_1 \times \text{id})(\text{id} \times \sigma)(\text{id}, \pi_2) \\
= f^*(\text{id} \times \sigma).
\]

Finally note that the universal property of a FPO ensures Ω and σ are determined up to isomorphism.

\[
\square
\]

3.4 The Categorical Logic Correspondence

Now we have all the ingredients to describe the usual categorical logic correspondence for FIX\(\_\) theories and FIX categories.

**Proposition 3.4.1** Given a FIX category \(\mathcal{C}\), we can define a certain FIX\(\_\) theory, which we denote by \(Th(\mathcal{C})\).

**Proof** The basic ground types are the objects of \(\mathcal{C}\). For each morphism

\[
f: A_1 \times \ldots \times A_n \rightarrow B
\]

in \(\mathcal{C}\) there is a basic function symbol \(f: A_1, \ldots, A_n \rightarrow B\). There is clearly a canonical structure \(G\) for this signature in \(\mathcal{C}\). The terms of the theory are then generated up according to the rules on Page 27. The axioms of \(Th(\mathcal{C})\) are specified by

\[
\Gamma \vdash M = N: \alpha \text{ is an axiom of } Th(\mathcal{C}) \iff [\Gamma.M]_G = [\Gamma.N]_G.
\]

\[
\square
\]

**Proposition 3.4.2** For each FIX\(\_\) theory, \(Th\), over some signature, \(Sg\), we can construct a syntactic FIX category which we denote by \(\mathcal{C}(Th)\).

**Proof**

- The objects of \(\mathcal{C}(Th)\) are the types of the signature \(Sg\).
- The morphisms with domain \(\alpha\) and codomain \(\beta\) are specified by

\[
\mathcal{C}(Th)(\alpha, \beta) \overset{\text{def}}{=} \{M(x) \mid x: \alpha \vdash M(x): \beta \} / \sim,
\]

where the equivalence relation \(\sim\) is defined by

\[
M(x) \sim M'(y) \text{ iff } x: \alpha \vdash M(x) = M'(x): \beta.
\]

40
Composition is given by the usual substitution of terms; it is a tedious but straightforward task to check that this does define a FIX category.

**Theorem 3.4.3** Given a FIX category $C$, then there is an equivalence of FIX categories
\[ Eq : C(Th(C)) \simeq C : Eq^{-1} \]
where $Eq$ and $Eq^{-1}$ are FIX category morphisms.

**Proof** Define $Eq$ and $Eq^{-1}$ by setting

- $Eq(\alpha) \overset{\text{def}}{=} [\alpha]_G$ and $Eq^{-1}(A) \overset{\text{def}}{=} A$ on objects, and
- $Eq(M(x)) \overset{\text{def}}{=} [x.M(x)]_G$ and $Eq^{-1}(f) \overset{\text{def}}{=} f(x)$ on morphisms.

Note that $Eq$ is well defined by appealing to Theorem 3.2.4. That we have an equivalence of categories via inverse FIX category morphisms is a lengthy calculation which is omitted.

### 3.5 Definability of Fixpoints

**Fixpoints in $\text{FIX}_\omega$**

The fixpoint type is so called because in its presence one can always define fixpoint terms at all types of the form $\alpha \to T\beta$. We make this precise in the next proposition:

**Proposition 3.5.1** ["Fixpoint Definability"] In the presence of a fixpoint object, one may define expressions $Y_{\alpha,\beta}$ of the meta $\lambda$ calculus with arity $\text{TERM} \to \text{TERM}$ for which given a FIX term in context $\Gamma \vdash F : (\alpha \to T\beta) \to (\alpha \to T\beta$ we may derive
\[ \Gamma \vdash Y_{\alpha,\beta}(F) : \alpha \to T\beta \quad \text{and} \quad \Gamma \vdash FY_{\alpha,\beta}(F) = Y_{\alpha,\beta}(F) : \alpha \to T\beta. \]

**Proof** We define $Y_{\alpha,\beta}$ by giving the representative
\[ Y_{\alpha,\beta}(f) \overset{\text{def}}{=} \lambda x.\lambda \alpha (\lambda (e.\lambda x.(e.y.fyx), \sigma(\omega))). \]

It is easy to see that the first judgement is derivable. For the second let us put $G \overset{\text{def}}{=} e.\lambda x.(e.y.fyx)$. Then
\[ Y_{\alpha,\beta}(F) = \lambda x.\lambda \alpha (\lambda (e.\lambda x.(e.y.fyx), \sigma(\omega))) \]
\[ = \lambda x.\lambda \alpha (\lambda \omega (\lambda n.(\lambda x.\lambda y.(y.fyx)), \sigma(\omega))) \]
\[ = \lambda x.\lambda \alpha (\lambda \omega (\lambda n.(\lambda \omega (\lambda x.\lambda y.(y.fyx)), \sigma(\omega))), \sigma(\omega))) \]
\[ = \lambda x.\lambda \alpha (\lambda \omega (\lambda n.(\lambda x.\lambda y.(y.fyx)), \sigma(\omega))), \sigma(\omega))) \]
\[ = \lambda x.\lambda \alpha (\lambda \omega (\lambda n.(\lambda x.\lambda y.(y.fyx)), \sigma(\omega))), \sigma(\omega))) \]
\[ = FY_{\alpha,\beta}(F). \]
Fixpoints in $\omega Cpo$

Using the categorical logic correspondence we can easily see that in a FIX category fixpoints of certain morphisms always exist. In order to illustrate this we apply the categorical equivalent of Proposition 3.5.1 on Fixpoint Definability to the FIX category $\omega Cpo$.

Suppose that $D$ is an $\omega$cpo and that $D_\bot$ is its lifting. Write $[D, D_\bot]$ for the continuous maps from $D$ to $D_\bot$. Then it is well known that any continuous map

$$\phi: [D, D_\bot] \rightarrow [D, D_\bot]$$

has a least fixpoint. Now the categorical version of Proposition 3.5.1 on Fixpoint Definability says that a fixpoint of $\phi$ should be given by $it(\phi)(\top)$ where we note that in $\omega Cpo$ it is the case that $\omega \overset{\text{def}}{=} [\top], \top = \sigma([\top])$ and $it(\phi)$ arises as the unique mediating morphism of the following diagram

$$\begin{array}{ccc}
\Omega_\bot & \xrightarrow{\sigma} & \Omega \\
\downarrow^{it(\phi)_\bot} & & \downarrow^{it(\phi)} \\
[D, D_\bot]_\bot & \xrightarrow{\phi_\bot} & [D, D_\bot]
\end{array}$$

It is easy to see, using the commutativity of the diagram, that given $n \in \Omega/\{\top\}$ we have $it(\phi)(n) = \phi^n(\bot)$ and that from the continuity of $it(\phi)$

$$it(\phi)(\top) = \bigvee_{n \in \mathbb{N}} \phi^n(\bot).$$

Thus $it(\phi)(\top)$ is exactly the least fixpoint of $\phi$ with respect to the order on $[D, D_\bot]$; of course the argument above is really the proof that $\omega Cpo$ has a FPO.

A Category without a Fixpoint Object

It is not always the case that a concrete category of domains has a FPO even though the morphisms between lifted domains may be guaranteed to have fixpoints.

Definition 3.5.2 Let $OnCpo$ be the category which has

- objects posets possessing suprema of all chains and
- morphisms monotone set functions; (we will call them maps).

It is easy to see that this category is indeed a let ccc when we regard the lifting functor as giving rise to a strong monad. It is the case that all maps $f: D_\bot \rightarrow D_\bot$
have a least fixpoint. For given any such map $f$, define for any ordinal $\alpha$ the element $f^{\alpha}(\bot)$ by

$$
\begin{align*}
    f^0(\bot) &= \bot \\
    f^{\alpha+1}(\bot) &= f(f^{\alpha}(\bot)) \\
    f^\lambda(\bot) &= \bigvee_{\alpha<\lambda} f^{\alpha}(\bot) \quad \text{where } \lambda \text{ is a limit ordinal.}
\end{align*}
$$

This is a good definition. The only thing that is not trivial is the existence of $f^{\lambda}(\bot)$: the set $\{f^{\alpha}(\bot) \mid \alpha < \lambda\}$ must be a chain. But a simple transfinite induction shows that $\alpha \leq \alpha' < \lambda$ implies $f^{\alpha}(\bot) \leq f^{\alpha'}(\bot)$. Next note that there is some ordinal $\beta$ for which $f^{\beta}(\bot)$ is a least fixpoint of $f$. Suppose this were not the case. By appealing to Hartog’s Lemma, we can find a least ordinal (say $\gamma$) whose cardinality is strictly greater than the cardinality of the domain of $f$, say $|D\bot|$. Using the hypothesis, it must be the case that the cardinality of $\{f^{\alpha}(\bot) \mid \alpha \leq \gamma\}$ is strictly greater than $|D\bot|$, a contradiction.

**Proposition 3.5.3** The let ccc OnCpo does not possess a fixpoint object.

**Proof** As OnCpo is cartesian closed we may appeal to Lemma 2.3.3.

Let us suppose that the fixpoint object $\Omega$ exists in OnCpo. We write $i: \Omega \hookrightarrow \Omega_\bot, \, n \mapsto [n]$ for the (monic) component of the unit of the lifting monad at $\Omega$. From the equaliser condition of the fixpoint object, $i\sigma: \Omega_\bot \rightarrow \Omega_\bot$ has a unique fixpoint (which is not bottom), say $[T] \in \Omega_\bot$. From remarks above there is an ordinal $\beta$ for which $(i\sigma)^{\beta}(\bot) = [T]$; note that $\beta > 1$.

We write $\sigma^1$ for $\sigma(\bot)$, $\sigma^{\alpha+1}$ for $\sigma[\sigma^\alpha]$ and $\sigma^\lambda$ for $\bigvee_{\alpha<\lambda} \sigma^\alpha$; note that each supremum exists.

The ordinals $\omega + 2$ and $\omega + 1$ are objects of OnCpo; we take $\omega \overset{\text{def}}{=} \{1, 2, \ldots\}$. Define a map $f: (\omega + 2)_\bot \rightarrow \omega + 2$ by setting

$$
    f(x) \overset{\text{def}}{=} \begin{cases} 
        1 & \text{if } x = \bot \\
        n + 1 & \text{if } x = [n] \\
        \omega & \text{if } x = [\omega] \\
        \omega + 1 & \text{if } x = [\omega + 1]
    \end{cases}
$$

and a map $f_r: (\omega + 1)_\bot \rightarrow \omega + 1$ to be $f$ with restricted (co)domain.

Consider the diagram

\[
\begin{array}{ccc}
\Omega_\bot & \xrightarrow{\sigma} & \Omega \\
\downarrow j & (1) & \downarrow j_r \\
(\omega + 1)_\bot & \xrightarrow{f_r} & \omega + 1 \\
\downarrow j & (2) & \downarrow j \\
(\omega + 2)_\bot & \xrightarrow{f} & \omega + 2
\end{array}
\]
(1) commutes using the universal property of a FPO, (2) trivially. Similarly, there is $\tilde{f}: \Omega \rightarrow \omega + 2$ making

$$
\begin{array}{c}
\Omega_{\perp} \xrightarrow{\sigma} \Omega \\
\downarrow \tilde{f}_{\perp} \quad (3) \quad \downarrow \tilde{f} \\
(\omega + 2)_{\perp} \xrightarrow{f} \omega + 2
\end{array}
$$

commute. From uniqueness, $\tilde{f} = j \tilde{f}_{r}$. We shall now consider the cases when $\beta$ is strictly less than, or greater than, $\omega$. In the latter case we obtain a contradiction by defining a map different from $\tilde{f}$ which makes (3) commute.

(Case $1 < \beta < \omega$): By chasing (1) we see that for any finite ordinal $k$, $\tilde{f}_{r}(\sigma^{k}) = k$. From the definition of $\beta$ it is easy to see that $\sigma^{\beta} = \top$. Chasing (1) at $[\top] \in \Omega_{\perp}$ we get

$$\beta = \tilde{f}_{r}(\top) = \tilde{f}_{r}[\sigma([\top])] = f_{r}[\tilde{f}_{r}([\top])] = f_{r}([\tilde{f}_{r}(\top)]) = \beta + 1$$

a contradiction. Hence we must have

(Case $\omega < \beta$): Certainly $\sigma^{k} \leq \sigma^{\omega}$ for any finite ordinal $k$, and so $k = \tilde{f}_{r}(\sigma^{k}) \leq \tilde{f}_{r}(\sigma^{\omega})$. Hence $\tilde{f}_{r}(\sigma^{\omega}) = \omega$. As $\sigma^{\beta} = \top$ we have $\omega = \tilde{f}_{r}(\sigma^{\omega}) \leq \tilde{f}_{r}(\top)$ and so $\tilde{f}_{r}(\top) = \omega$.

Define a function $F: \Omega \rightarrow \omega + 2$ by

$$F(n) \overset{\text{def}}{=} \begin{cases} 
\omega + 1 & \text{if } \top \leq n \\
\tilde{f}(n) & \text{otherwise}
\end{cases}$$

Note that $F(\top) = \omega + 1$ and $\tilde{f}(\top) = j \tilde{f}_{r}(\top) = \omega$, that is $F \neq \tilde{f}$. It is the case that $F$ is monotone:

1. On elements of $\Omega$ not greater than $\top$, $F$ is monotone for $\tilde{f}$ is.
2. If $\top \leq n \leq n'$ in $\Omega$ then $F(n) = F(n')$.
3. If $n \leq n'$ in $\Omega$ where $n'$ is greater than $\top$ but $n$ is not, then $F(n) \leq \omega + 1 = F(n')$.

Finally, $F$ makes the square (3) commute.

1. Clearly $\sigma^{1} \leq \top$ and $\sigma^{1}$ is not $\top$. So $F(\top) = \tilde{f}(\sigma^{1}) = 1 = \tilde{f}_{\perp}(\perp)$.

2. Suppose $[n] \in \Omega_{\perp}$ and $n$ is greater than $\top$. Then $\top = \sigma([\top]) \leq \sigma([n])$. So

$$F(\sigma([n])) = \omega + 1 = f([F(n)]) = fF_{\perp}([n]).$$

3. Suppose $[n] \in \Omega_{\perp}$ and $n$ is not greater than $\top$. Then $\sigma([n])$ is not greater than $\top$, for if so, as $\sigma$ is an isomorphism, $[\top] = \sigma^{-1}(\top) \leq [n]$ and this is not so. Hence,

$$F(\sigma([n])) = \tilde{f}(\sigma([n])) = f(\tilde{f}_{\perp}([n])) = f([\tilde{f}(n)]) = f([F(n)]) = fF_{\perp}([n]).$$

By the uniqueness criterion, we have $F = \tilde{f}$. This is not so. Hence there can be no fixpoint object in $\text{OnCpo}$, as claimed. \qed
3.6 Functional Completeness

A concept which is closely related to the correspondence between \( \text{FIX} = \) theories and \( \text{FIX} \) categories is functional completeness. We begin by defining the notion of functional completeness for let ccc’s and show these categories are functionally complete. We refer to [LS86] for a similar discussion concerning cartesian closed categories.

**Definition 3.6.1** Let \( C \) be a let ccc and let \( A \) be an object of \( C \). The *polynomial category* \( C[X] \) in variable \( X \) is specified by the following data:

- The objects of \( C[X] \) are just the objects of \( C \) and
- a morphism of \( C[X] \) is an equivalence class, obtained by quotienting the collection consisting of the morphisms of \( C \) together with an indeterminate global element \( X: 1 \to A \) by the equivalence relation \( \sim \), where \( \sim \) is the least such relation satisfying:

1. If \( fg = h \) in \( C \), then \( gf \sim h \).
2. If \( u \sim u' \) and \( v \sim v' \), then \( vu \sim v'u' \).
3. \( u \circ id \sim u \sim id \circ u \).
4. \( (uv)u \sim w(vu) \).
5. Conditions forcing (formal) cartesian closure of \( C[X] \); see [LS86].
6. If \( \text{lift}(f) = h \) in \( C \), then \( \text{lift}(f) \sim h \) in \( C[X] \).
7. If \( u \sim u' \) then \( \text{lift}(u) \sim \text{lift}(u') \).
8. Conditions forcing \( C[X] \) to be a let category; for example, this amounts to requiring

\[
\text{lift}(v(u \times id)) \sim \text{lift}(v)(u \times id),
\]

corresponding to \( \text{LiftS} \) of Definition 1.3.2; similar conditions hold for the other let structure equations.

**Remark 3.6.2** The polynomial category in \( n \) variables, \( C[X_1 \ldots X_n] \), is defined by iterating the construction just given.

Now we prove a version of functional completeness for let ccc’s. If we assume that we have already the categorical logic correspondence for let ccc’s, then we may prove the next theorem using internal languages. Alternatively, the theorem can be proved with bare hands, and the categorical logic developed in the same way that Lambek and Scott prove an equivalence between ccc’s and typed lambda calculus.
**Theorem 3.6.3** ["Functional Completeness"] Let \( C \) be a let category and \( C[X] \) its polynomial category. For every morphism \( u : B \to C \) in \( C[X] \) there is a unique morphism

\[
\Lambda(u) : A \times B \to C
\]

in \( C \) such that

\[
\Lambda(u)(X!, id) = u
\]

where \( ! : B \to 1 \). In particular, each global element of \( C \) in \( C[X] \) is of the form \( fX \) for some unique morphism \( f : A \to C \) in \( C \). Note that we now write \( = \) for \( \sim \), that is, for equality in the polynomial category.

**Proof** As there is a proof of this result for ccc’s in [LS86], we just give details of the proof for the let structure. Take morphisms

\[
u : B \times B' \to TC,
\]

and hence \( \text{lift}(u) : B \times TB' \to TC \),

\[
l : (A \times B) \times B' \to A \times (B \times B'),
\]

\[
m : A \times (B \times TB') \to (A \times B) \times TB',
\]

where \( l \) and \( m \) are the obvious isomorphisms. By induction, we shall assume that there is a morphism

\[
\Lambda(u) : A \times (B \times B') \to TC
\]

that satisfies functional completeness. Then we define

\[
\Lambda(\text{lift}(u)) \overset{\text{def}}{=} \text{lift}(\Lambda(u)l)m,
\]

and refer the reader to [LS86] for the definition of \( \Lambda \) on the ccc structure. We have to check that this is well defined, i.e. if \( u = v \) in \( C[X] \) then \( \Lambda(u) = \Lambda(v) \) in \( C[X] \). This amounts to showing that \( \Lambda \) respects each of conditions (1) to (8) of Definition 3.6.1; most of these are easy to verify, but we check in detail one of the let structure equations of condition (8), namely \( \text{lift}(v(u\pi, \pi')) = \text{lift}(v)(u\pi, \pi') \). We have

\[
\Lambda(\text{lift}(v(u\pi, \pi'))) = \text{lift}(\Lambda(v)(u\pi, \pi')l)m
\]

by definition is

\[
\text{lift}(\Lambda(v)(\pi, (\Lambda(u)(\pi, \pi')(\pi', \pi'))))(\pi, (\pi', \pi'))(\pi, (\pi', \pi'))m
\]

which is

\[
\text{lift}(\Lambda(v)(\pi, (\Lambda(u)(\pi, \pi'))m)
\]

for appropriate \( l' \)

\[
\text{lift}(\Lambda(v)l'(\pi, (\Lambda(u) \times id))m)
\]

from the let structure

\[
\text{lift}(\Lambda(v)(\pi, (\Lambda(u))(\pi'))m
\]

\[
= \text{lift}(\Lambda(v)l'(\pi, (\Lambda(u)(\pi, \pi'), \pi'))
\]

\[
= \Lambda(\text{lift}(v))(\pi, (\Lambda(u)(\pi')))
\]

\[
= \Lambda(\text{lift}(v))(u\pi, \pi')
\]

which is what we had to show. Now that we know \( \Lambda \) is well defined we prove the result itself. Indeed,

\[
\Lambda(\text{lift}(u))(X!, id) = \text{lift}(\Lambda(u)l)m(X!, id)
\]

46
\[
\text{which as } C[X] \text{ is a let ccc } \Rightarrow \text{lif}((\Lambda(u)l)((X, id) \times id)) = \text{lif}((\Lambda(u)l)((X!, id) \times id)) = \text{lif}(\Lambda(u)(X!, id))
\]

and by induction \( = \text{lif}(u) \).

Hence the proof is complete. \( \Box \)

Thus we have presented a proof of the functional completeness result by direct calculation. As remarked above, we can then use the result to derive the categorical logic correspondence. For an explanation of the general ideas, see [LS86].

**Theorem 3.6.4** Given a FIX category \( C \), then there is an equivalence of FIX categories

\[
Eq : C(Th(C)) \simeq C,
\]

where \( Eq \) is a FIX category morphism.

**Proof (Sketch)** The types of the theory \( Th(C) \) are the objects of \( C \) and the terms of the theory \( Th(C) \) of type \( A \) are defined to be global elements in \( C[X_1 \ldots X_n] \) of the object \( A \). The rules of inference for finite products and lambda terms can be found in [LS86]. For the let structure suppose that we are given the terms \( E : 1 \rightarrow TA \) and \( M : 1 \rightarrow TB \) in \( Th(C) \). Then the term \( \text{Let}(E, X, M) \) is defined to be

\[
\text{lif}(\Lambda(M)i)(\text{id}, E) : 1 \rightarrow TB
\]

where \( i \) is the isomorphism \( 1 \times A \cong A \times 1 \). Equality of terms is given by equality in \( C[X_1 \ldots X_n] \).

The category \( C(Th(C)) \) has objects the types of \( Th(C) \) and morphisms terms of \( Th(C) \) with one free variable. Now define \( Eq \) by the following recipe:

- Set \( Eq(A) \overset{\text{def}}{=} A \) and
- given that \( (X : A, M(X) : B) : A \rightarrow B \) in \( C(Th(C)) \) where of course \( X : 1 \rightarrow A \) and \( M(X) : A \rightarrow B \) in \( C[X] \), we put

\[
Eq(X : A, M(X) : B) \overset{\text{def}}{=} \Lambda(M(X) \circ X)\theta
\]

where \( \theta : A \cong A \times 1 \) in \( C \) and we have made use of Theorem 3.6.3. The remainder of the proof is routine calculation. \( \Box \)
3.7 Further Results about FIX Categories and FIX\(_\equiv\) Theories

The Proof of Lemma 2.3.3

**Proof** Suppose that \( C \) is a let \( ccc \) and that the triple \((\omega, \sigma, \Omega)\) is a FPO satisfying the hypotheses of Lemma 2.3.3. Let \( f:C \times TA \rightarrow A \). We shall use the categorical logic correspondence and work with the internal language of \( C \). We need to find a unique morphism \( \tilde{f}:C \times \Omega \rightarrow A \) such that

\[
\tilde{f}(id \times \sigma) = f(\pi_1, \text{lift}(\eta \tilde{f})).
\]  

(3.15)

With a view to using the uniqueness property of the \( T \) algebra, we look for a morphism (say \( g \)) of the form \( g:T(C \rightarrow A) \rightarrow (C \rightarrow A) \). Define such a \( g \) via the term in context

\[
e: T(C \rightarrow A) \vdash \lambda_C (c.f(c, \text{Let}(e, x.\text{Val}(xc)))): (C \rightarrow A).
\]

Let us write \( F(e) \) for the raw term (in context \( e \)). From this, we can define \( \tilde{f} \) by the term in context

\[
c: C, n: \Omega \vdash \text{lt}(F, n)c: A.
\]

Let \( u: T\Omega \). Using the rules of the logic \( \text{FIX}_\equiv \) we get

\[
c, u: T\Omega \vdash \text{lt}(F, \sigma(u))c = F(\text{Let}(u, y.\text{Val}(\text{lt}(F, y))))c
\]

by definition of \( F(e) \)

\[
= f(c, \text{Let}(u, y.\text{Val}(\text{lt}(F, y))), x.\text{Val}(xc))
\]

\[
= f(c, \text{Let}(u, y.\text{Let}(\text{Val}(\text{lt}(F, y)), x.\text{Val}(xc)))
\]

\[
= f(c, \text{Let}(u, y.\text{Val}(\text{lt}(F, y)c))).
\]

This says exactly that the equation 3.15 holds in \( C \), as desired, with uniqueness immediate from the \( \text{FIX}_\equiv \) rules.

Conversely, given the existence of a \( TC \) algebra for each \( C \), just take \( C \) to be \( 1 \) to get the required \( T \) algebra. \( \square \)

Elementary Domain Theoretic Features of FIX\(_\equiv\)

\( \text{FIX}_\equiv \) has certain features which seem to be close in spirit to those of axiomatic domain theory and some properties of the abstract categorical semantics are very similar to those of the concrete model \( \omega \text{Cpo} \). We note certain results concerning \( \text{FIX}_\equiv \) which have well known analogues in \( \omega \text{Cpo} \) and begin with the following lemma:

**Lemma 3.7.1** Work in an arbitrary \( \text{FIX} \) category. We can define a morphism \( \uparrow_A: \Omega \rightarrow TA \) which is unique such that \( \text{let}(\uparrow_A) = \uparrow_A \sigma \).

**Proof** Set \( \uparrow_A \overset{\text{def}}{=} \text{it}(\text{let}(\text{id}_{TA})) \). Note that \( \text{let}(\text{id})\text{let}(\eta \uparrow_A) = \text{let}(\text{let}(\text{id})\eta \uparrow_A) = \text{let}(\uparrow_A) \).

Hence the result follows from the universal property of the FPO. \( \square \)
Corollary 3.7.2 Given a FIX category \( C \) and a morphism \( f: A \to TB \) then the following diagram commutes:

\[
\begin{array}{ccc}
\Omega & \xrightarrow{\text{let}(f)} & \Omega \\
\uparrow A & & \uparrow B \\
TA & \xrightarrow{\text{let}(f)} & TB
\end{array}
\]

**Proof** Note that \( \text{let}(\text{let}(f)\uparrow A) = \text{let}(f)\text{let}(\uparrow A) = \text{let}(f)\uparrow A\sigma \). Then the result is immediate from Lemma 3.7.1.

For any object \( A \) of the FIX category \( C \) there is a morphism \( \bot_A: 1 \to TA \) which is defined to be \( \uparrow A\sigma \). In the concrete FIX category \( \omega CPo \), the morphism \( \uparrow A: \Omega \to A_\bot \) is of course the continuous function which is constantly bottom. Thus the morphism \( \bot_A: 1 \to A_\bot \) just selects the bottom element from the domain \( A_\bot \).

A question that remains unanswered is just how like axiomatic domain theory is the FIX logic? For example, how do abstract fixpoints in FIX relate to least fixpoints in the category of domains \( \omega CPo \)? We shall return to these issues in Chapter 10.

**Fixpoint Objects in Polynomial Categories**

**Proposition 3.7.3** Let \( C \) be a FIX category with FPO \( \Omega \). Then \( C[X] \) also has a FPO, given by \( i(\Omega) \), where \( i: C \hookrightarrow C[X] \) is the canonical inclusion functor.

**Proof** We show that the category \( C[X] \) has a FPO by appealing to Lemma 2.3.3. Consider the diagram:

\[
\begin{array}{ccc}
T\Omega & \xrightarrow{\sigma} & \Omega \\
\downarrow \text{let}(\eta h) & & \downarrow \text{let}(\Lambda(f)) \\
A \times T\Omega & \xrightarrow{id \times \sigma} & A \times \Omega \\
\downarrow k & & \downarrow \text{let}(\Lambda(f)) \\
A \times TB & \xrightarrow{\Lambda(f)} & B \\
\downarrow \text{let}(f) & & \downarrow \text{let}(f) \\
TB & \xrightarrow{f} & B
\end{array}
\]
where \( k \overset{\text{def}}{=} \langle \pi_A, \text{lift}(\eta \text{it}(\Lambda(f))) \rangle \). We set \( h \overset{\text{def}}{=} \text{it}(\Lambda(f))(X!, id) \), where the morphism \( \Lambda(f) \) is defined by appealing to Theorem 3.6.3. In order to prove that \( h \sigma = \text{flet}(\eta g) \) we inspect the diagram above. It is clear all regions commute except for \( k(X!, id) = \langle X!, id \rangle \text{let}(\eta h) \). To prove this it is enough to show that \( \text{lift}(\eta \text{it}(\Lambda(f)))(X!, id) = \text{let}(\eta \text{it}(\Lambda(f)))(X!, id) \). We appeal to Theorem 3.6.3 and note

\[
\begin{align*}
\Lambda(\text{let}(\eta \text{it}(\Lambda(f))(X!, id))) &= \text{lift}(\Lambda(\eta \text{it}(\Lambda(f)))(X!, id)) \\
&= \text{lift}(\eta \pi'(\pi, \text{it}(\Lambda(f))\pi')\langle \pi, \pi' \rangle) \\
&= \text{lift}(\eta \text{it}(\Lambda(f))(\pi, \pi')).
\end{align*}
\]

It remains to prove uniqueness. Suppose also that \( g \sigma = \text{flet}(\eta g) \). Note that if \( \Lambda(g) = \text{it}(\Lambda(f)) \) then \( h = \text{it}(\Lambda(f))(X!, id) = \Lambda(g)(X!, id) = g; \) so it is sufficient to prove the former. For this, if we can show \( \Lambda(g)(id \times \sigma) = \Lambda(f)(\pi_A, \text{lift}(\eta \Lambda(g))) \) we are done using the universal property of the FPO \( \Omega \) in \( C \). As \( \Lambda(g \sigma) = \Lambda(g)(id \times \sigma) \) it is sufficient to prove \( \Lambda(f)(\pi_A, \text{lift}(\eta \Lambda(g)))(X!, id) = g \sigma. \) We have

\[
\begin{align*}
\Lambda(f)(\pi_A, \text{lift}(\eta \Lambda(g)))(X!, id) &= \Lambda(f)(X!, \text{lift}(\eta \Lambda(g))(X!, id)) \\
&= \Lambda(f)(X!, \text{let}(\eta g)) \\
&= \text{flet}(\eta g)
\end{align*}
\]

and so we are done. Finally, the equaliser condition is simple to verify. \( \square \)

\section*{Completeness of the Models of FIX\(_{=}\) Theories}

\textbf{Theorem 3.7.4} The semantics which we have given to FIX\(_{=}\) theories \( Th \) is both sound and complete. By complete, we mean that an equation in context is a theorem of \( Th \) just in case it is satisfied by all models of \( Th \).

\textbf{Proof} We proved soundness on Page 35. An equation \( E \) is a theorem of the theory \( Th \) just in case it is satisfied by the generic model \( G \). But if \( E \) is satisfied by all models, in particular it is satisfied by \( G \). \( \square \)

\textbf{Remark 3.7.5} It is possible to check that for any FIX category \( D \) and model \( M \) of \( Th \) in \( D \) there is an essentially unique FIX category morphism \( I:C(Th) \rightarrow D \) for which we have \( I[\Gamma.M]_G = [\Gamma.M]_M \). In particular, if \( Th \) is the pure FIX\(_{=}\) theory (no extralogical axioms), then \( C(Th) \) is (essentially) an initial object in the category of FIX categories and FIX category morphisms.

\section*{3.8 Gluing for Let Cartesian Closed Categories}

The technique of gluing originated with Freyd, who presented a neat method for proving the existence and disjunction properties of certain intuitionistic type theories. His proof made use of a certain topos \( \mathcal{E} \) manufactured from two other toposes; \( \mathcal{E} \) is the so-called glued topos and for an account of this see [LS86]. The essence of
the method involves the careful application of a certain theorem from topos theory. A simple version of the theorem just for ccc’s can be found in [Laf88]. We now prove a version of the theorem for let ccc’s.

**Lemma 3.8.1 [“Let ccc Gluing”]** Let \( \Gamma: \mathcal{D} \to \mathcal{C} \) be a functor where \( \mathcal{D} \) is a let ccc and \( \mathcal{C} \) is a ccc. Suppose also that \( \mathcal{C} \) has pullbacks and that \( \Gamma \) preserves finite products. Write \( \mathcal{GL}(\Gamma) \) for the category \( (\mathcal{C}, \Gamma) \) and note that there is an obvious functor \( \pi: (\mathcal{C}, \Gamma) \to \mathcal{D} \). Then it is the case that

1. \( \mathcal{GL}(\Gamma) \) is a let ccc.
2. \( \pi \) is a morphism of let ccc’s.

**Proof** It is a well known result that \( \mathcal{GL}(\Gamma) \) is a ccc, for example see [Laf88]. We shall denote a typical morphism in \( \mathcal{GL}(\Gamma) \) by

\[(a, s): (A, f, X) \to (B, g, Y).\]

Note that the property of being a let ccc is not a categorical property. By the statement that \( \mathcal{GL}(\Gamma) \) is a let ccc, we mean that there is an obvious canonical choice for a let structure. We make the following definitions:

1. \( T(A, f, X) \overset{\text{def}}{=} (A, \Gamma(\eta)f, TX). \)
2. \( \eta_{(A,f,X)} \overset{\text{def}}{=} (id, \eta): (A, f, X) \to T(A, f, X). \)
3. \[
\frac{(a, s): (A, f, X) \times (B, g, Y) \to T(C, h, Z)\quad \text{lift}(a, s) \overset{\text{def}}{=} (a, \text{lift}(s)): (A, f, X) \times T(B, g, Y) \to T(C, h, Z)}{
(a,s):(A,f,X)\to(B,g,Y)\quad T(a,s):(A,f,X)\to T(B,g,Y)\quad T(C,h,Z)}
\]

The first two definitions clearly make sense. We note that the third definition is good:

\[
\begin{array}{ccc}
A \times B & \xrightarrow{f \times g} & \Gamma X \times \Gamma Y \\
\downarrow a & & \cong \\
C & \xrightarrow{\Gamma(\eta)} & \Gamma X \times \Gamma Y \\
\end{array}
\]

We have to verify that the equations of Definition 1.3.2 on page 12 hold. We just check \( \text{LiftA} \). Take morphisms

\[
(a, s): (C, h, Z) \times (A, f, X) \to T(B, g, Y)
\]
\[
(b, t): (C, h, Z) \times (B, g, Y) \to T(D, k, W)
\]
\[
(\pi, \pi'): (C, h, Z) \times (A, f, X) \to (C, h, Z).
\]

51
Consider the commutative diagram:

\[
\begin{array}{ccccccc}
C \times A & \xrightarrow{\langle \pi, a \rangle} & C \times B & \xrightarrow{b} & D \\
\downarrow h & & \downarrow h \times f & & \downarrow h \times \Gamma(\eta)g \\
\Gamma Z \times \Gamma TX & \xrightarrow{id \times \Gamma(\eta)} & \Gamma Z \times \Gamma X & \xrightarrow{\cong} & \Gamma Z \times \Gamma TY \\
\downarrow \cong & & \downarrow \cong & & \downarrow \Gamma(\eta)k \\
\Gamma(\xi \times TX) & \xrightarrow{\Gamma(id \times \eta)} & \Gamma(\xi \times X) & \xrightarrow{\cong} & \Gamma(\xi \times TY) \\
\downarrow \cong & & \downarrow \Gamma(id \times \eta) & & \downarrow \cong \\
\Gamma(\xi \times TX) & \xrightarrow{\Gamma(lift(t)) \langle \pi, s \rangle)} & \Gamma(\xi \times T^W) & \xrightarrow{\cong} & \Gamma TW \\
\end{array}
\]

From this, it is easy to see that

\[
lift(lift(b, t) \circ \langle \pi, \pi', (a, s) \rangle) = lift(lift(b, t) \circ \langle \pi, a, \langle \pi', s \rangle \rangle)
\]

and using the diagram

\[
lift(b, t) \circ \langle \pi, a, \langle \pi', lift(s) \rangle \rangle = lift(b, t) \circ \langle \pi, (\pi', (a, lift(s))) \rangle.
\]

This is exactly LiftA for the glued category \(\mathcal{G}l(\Gamma)\). It is immediate that \(\pi\) is a morphism of the ccc's.

Let \(U\) be the forgetful functor from the category of locally small let ccc's to the category of locally small categories. There is, of course, a free functor \(F\) from the category of locally small categories to the category of locally small let ccc's, where on objects we write \(\mathcal{F}C\) for \(F(C)\). Then \(F\) is left adjoint to \(U\) and we write \(I\) for the unit of the adjunction; thus there is for each locally small \(C\) a canonical functor \(I_C : C \rightarrow \mathcal{F}C\). Now we can prove

**Corollary 3.8.2** Let \(C\) be a locally small category, and \(\mathcal{F}C\) the freely generated let ccc. Then the canonical functor \(I_C : C \hookrightarrow \mathcal{F}C\) is full and faithful.
Proof Consider the commutative diagram

\[
\begin{array}{ccc}
\mathcal{C} & \xrightarrow{I} & \mathcal{FC} \\
\downarrow H & \Phi & \downarrow \Phi \\
[C^{op}, \text{Set}] & \end{array}
\]

where \(H\) is the Yoneda embedding of \(\mathcal{C}\) into its topos of presheaves, and the functor \(\Phi\) arises (essentially) as the mate of \(H\) across the adjunction \((F \dashv U)\) where \([C^{op}, \text{Set}]\) is regarded as a let category with the identity strong monad. \(H\) is faithful, implying \(I\) is too.

Let \(\Gamma\) be the composite

\[
I^* \circ H : \mathcal{FC} \longrightarrow [\mathcal{FC}^{op}, \text{Set}] \longrightarrow [C^{op}, \text{Set}].
\]

There is certainly a natural transformation \(\alpha : \mathcal{C}(-, +) \longrightarrow \mathcal{FC}(I(-), I(+))\). So, for each \(A\) in \(\mathcal{C}\) there is a natural transformation

\[
\alpha_A : H_A \longrightarrow \Gamma \circ I(A) : \mathcal{C} \longrightarrow [C^{op}, \text{Set}].
\]

Thus we may define a functor

\[
J : \mathcal{C} \longrightarrow ([C^{op}, \text{Set}] \downarrow \Gamma)
\]

by setting \(J(A) \overset{\text{def}}{=} \alpha_A\) and \(J(f) \overset{\text{def}}{=} (f_*, \Gamma I(f))\). That \(J\) is well defined follows the naturality of \(\alpha\) and that \(([C^{op}, \text{Set}] \downarrow \Gamma)\) is a let ccc follows from Lemma 3.8.1.

If \(\pi : ([C^{op}, \text{Set}] \downarrow \Gamma) \rightarrow [C^{op}, \text{Set}]\) and \(\pi' : ([C^{op}, \text{Set}] \downarrow \Gamma) \rightarrow \mathcal{FC}\) are the usual projection functors, then clearly we have \(\pi J = H\) and \(\pi' J = I\).

The universal property of the category \(\mathcal{FC}\) says that the following diagram commutes up to natural isomorphism,

\[
\begin{array}{ccc}
\mathcal{C} & \xrightarrow{J} & ([C^{op}, \text{Set}] \downarrow \Gamma) & \xrightarrow{\pi'} & \mathcal{FC} \\
\downarrow I & & \downarrow K & & \downarrow \text{Id}_{\mathcal{FC}} \\
\mathcal{FC} & & & & \\
\end{array}
\]

where, say, \(\iota : K I \cong J\). Now, \(\pi' \iota : \pi' K I \cong \pi' J = I\). By the uniqueness condition of the universal property, there is a natural isomorphism \(\kappa : \pi' K \cong \text{Id}_{\mathcal{FC}}\). It is also clearly the case that \(\kappa I = \pi' \iota\).
Now take objects $A$ and $B$ in $C$ and a morphism $g: IA \to IB$ in $\mathcal{FC}$, and consider the diagram

\[
\begin{array}{cccc}
H_A & \xrightarrow{\pi J A} & \pi K I A & \\
\pi (\iota_B \circ Kg \circ \iota_A^{-1}) & & & \pi Kg \\
H_B & \xleftarrow{\pi J B} & \pi K I B & \\
\end{array}
\]

The Yoneda embedding is full, thus there is $f: A \to B$ in $C$ for which $f_\ast = \pi(h)$ where we set $h \overset{\text{def}}{=} \iota_B \circ Kg \circ \iota_A^{-1}$. Now, for each object $A$ in $C$, we have a natural transformation

\[\alpha_A: H_A = \pi J A \longrightarrow \Gamma \pi' J A = \Gamma I A.\]

This leads to

\[
\begin{align*}
\alpha_B f_\ast &= \alpha_B \circ \pi(h) \\
&= (\Gamma \circ \pi')(h) \circ \alpha_A \\
&= \Gamma(\kappa IB \circ \pi' Kg \circ \pi' \iota_A^{-1}) \circ \alpha_A \\
&= \Gamma(g) \circ \alpha_A \\
&= H^I_{\mathcal{g}}(\cdot) \circ \alpha_A
\end{align*}
\]

Hence it is the case that $\alpha_{B,A} \circ H_f^A = H^I_{\mathcal{g}} \circ \alpha_{A,A}$ and applying this to $id_A$ we get

\[I(f \circ id_A \circ id_A) = g \circ id_{IA} \circ id_{IA}\]

that is $I(f) = g$,

which says exactly that the functor $I$ is full. \hfill \Box

The last result follows from an adaptation of Pitts’ proof of the corresponding result for ccc’s. We may derive from Corollary 3.8.2 the following

**Proposition 3.8.3** Given a $\lambda ML_T$ theory $Th$, any term $M$ of ground type $\gamma$ containing no object level variables is provably equal in the equational logic of $\lambda ML_T$ to a ground term $M'$ of type $\gamma$ (A ground term is simply a raw term of $\lambda ML_T$ for which all function symbols are basic.)

**Proof** The term $M$ corresponds to a global element of the denotation of $\gamma$ in the classifying category of the theory $Th$. But by Corollary 3.8.2, this global element arises as a global element of the denotation of $\gamma$ in the syntactic category arising from the ground types and terms. This says exactly that $M$ is provably equal to a ground term $M'$ in the logic of $\lambda ML_T$. \hfill \Box
Presheaves on Categories with Monads

We finish this chapter with a miscellaneous result, namely:

**Proposition 3.8.4** Let $\mathcal{C}$ be a locally small category and $(T, \eta, \mu)$ a monad over $\mathcal{C}$. Then the category of presheaves on $\mathcal{C}$ is a left category for a certain choice of monad.

**Proof** We define a strong monad $(S, \varepsilon, \nu, \tau)$ on $[\mathcal{C}^{\text{op}}, \mathcal{S}et]$ by setting

- $SF(A) \overset{\text{def}}{=} F(TA)$ and $SF(f) \overset{\text{def}}{=} F(Tf)$,
- $(S\alpha)_A \overset{\text{def}}{=} \alpha_{TA}$,
- $(\varepsilon_F)_A \overset{\text{def}}{=} F(\eta_A)$,
- $(\nu F)_A \overset{\text{def}}{=} F(\mu_A)$ and
- $(\tau_{F,G})_A \overset{\text{def}}{=} F(\eta_A) \times id_{G(TA)}$

where $f: A \to A'$ is a morphism of $\mathcal{C}$ and $\alpha: F \to G$ is a morphism of $[\mathcal{C}^{\text{op}}, \mathcal{S}et]$. It is routine to check that that we have defined a strong monad and appealing to Lemma 1.3.5 we are done. \qed
Chapter 4

The FIX Logical System

4.1 Why Introduce the FIX Logic?

The definition of an initial $T$ algebra $\sigma:T\Omega \to \Omega$ for an endofunctor $T$ contains both an existence and a uniqueness clause. The uniqueness requirement amounts to a form of induction principle, which is stated precisely in the following theorem for which a reference is [LS81].

Theorem 4.1.1 ["Initial $T$ Algebra Induction Principle"] To show that a subobject $i:S \hookrightarrow \Omega$ is the whole of $\Omega$, it suffices to show that the composition $\sigma Ti:TS \to \Omega$ factors through $i:S \hookrightarrow \Omega$.

For the functor $(-)+1$ on the category of sets, the object part of the initial algebra is the natural numbers and the above theorem is equivalent to the usual principle of mathematical induction; this is a well known fact.

As another instance of initial $T$ algebra induction, we consider the case when the category is $\omega C P A$, the endofunctor is lifting and subobjects are given by inclusive subsets. Suppose that $i:S \hookrightarrow \Omega$ is an inclusive subset of the fixpoint object $\Omega = \{0 < 1 < \ldots < T\}$. Then we have that $S_\perp$ is just the inclusive subset of $\Omega_\perp$ given by $\{e \in \Omega_\perp \mid \forall n \in \Omega_\perp [n] = e \supset n \in S\}$. Thus we can state Theorem 4.1.1 by way of following induction principle:

$$\forall e \in \Omega_\perp. (\forall n \in \Omega_\perp [n] = e \supset n \in S) \supset \sigma(e) \in S \quad \Omega = S$$

Just as least fixed points are definable using the universal property of the initial $(-)_\perp$ algebra $\Omega$, so is Scott’s induction principle for least fixed points [Sco69b] derivable from the above induction rule.

Proposition 4.1.2 ["Scott Induction"] Let $P \subset D_\perp$ be an inclusive subset, and let $f:D_\perp \to D_\perp$ be a continuous function. Then we have

$$\perp \in P \quad \forall d \in D_\perp. d \in P \supset f(d) \in P \quad \text{fix}(f) \in P$$

Proof In Theorem 4.1.1 take $S \overset{\text{def}}{=} \{n \in \Omega \mid h(n) \in P\}$ where $h$ is the unique mediating morphism arising from $f_\perp : (D_\perp)_\perp \to D_\perp$ and the FPO $\Omega$. Then $S = \Omega$ and so fix$(f) = h(T) \in P$. □
In order to formulate this induction principle for the fixpoint type in $\text{FIX}_=$ we introduce a constructive logic [Bee85], called FIX, of properties of terms over $\text{FIX}_=$. There are similarities between FIX and the traditional "axiomatic domain theory" of LCF [Pau87] and to Plotkin’s approach to denotational semantics using partial continuous functions [Plo85].

### 4.2 The Predicate Logic FIX

The FIX propositions constitute part of a predicate logic with equality. The rules for equality, conjunction and universal quantification (over elements of a given type) form a fragment of first-order intuitionistic predicate calculus [Dum77]. Additionally there are certain predicate constructors which implicitly contain forms of implication, disjunction and existential quantification. In order to set up a formal system for our logic, we begin by defining an extension of the notion of $\text{FIX}_=$ signature, which was defined in Section 2.5.1.

**Signatures for FIX**

**Definition 4.2.1** A $\text{FIX}$ signature $\Sigma$ is specified as in Section 2.5.1, together with the following data:

- A collection of basic relation symbols, together with the following distinguished relation symbols: $=_{\alpha}$, $\text{true}$, $\text{false}$, $\&$, $\forall_{\alpha}$, $\square$, $\diamond$, $\vdash$.
- A sorting for each of the basic relation symbols, which is a list of $n$ types, and will be written:

$$R: \alpha_1, \ldots, \alpha_n.$$  

In the case that $n$ is one, we shall write $R: \alpha$. We say that $R$ is an $n$-ary basic relation symbol when its sorting consists of $n$ types.

We use the signature $\Sigma$ to define the propositions of our logic. Given such a $\Sigma$, we shall define from this an abstract syntax signature $\Sigma$. The collection of ground arities, $\text{GAr}$, is the set \{TERM, PROP\} and the collection of constants, $\text{Con}$, consists of all function symbols, all relation symbols, and a countably infinite set of object level variables. The function symbols have the same arities as those designated on Page 24 and the object level variables arity $\text{TERM}$. The $n$-ary relation symbols are considered to have arity $\text{TERM}^n \rightarrow \text{PROP}$, the distinguished relation symbols which will represent truth, falsity, equality, conjunction and universal quantification have their usual arities and the remaining distinguished relation symbols have the following arities:

1. $\vdash: (\text{TERM} \rightarrow \text{PROP}) \rightarrow (\text{TERM} \rightarrow \text{PROP}) \rightarrow \text{TERM} \rightarrow \text{PROP}$

2. $\square: \text{TERM} \rightarrow (\text{TERM} \rightarrow \text{PROP}) \rightarrow \text{PROP}$

60
3. $\diamond: \text{TERM} \to (\text{TERM} \to \text{PROP}) \to \text{PROP}$

Associated with a FIX signature $Sg$ is a collection of raw FIX terms and raw FIX propositions. These are the closed expressions of the abstract syntax generated from $\Sigma$ of arities TERM and PROP respectively.

**Propositions in Context for FIX**

We shall write $\Gamma \vdash \Phi$ prop

for the judgement that given the context $\Gamma$ the raw proposition $\Phi$ is well formed. These judgements are generated by the following rules, where in the case of the basic relation symbols, the sorting of a certain symbol is used to determine the form of the introduction rule.

<table>
<thead>
<tr>
<th>Basic Relation Symbols</th>
</tr>
</thead>
<tbody>
<tr>
<td>$\Gamma \vdash M_1: \alpha_1, \ldots, \Gamma \vdash M_n: \alpha_n$</td>
</tr>
<tr>
<td>$\Gamma \vdash R(M_1, \ldots, M_n)$ prop</td>
</tr>
<tr>
<td>where $R$ is a basic relation symbol with sorting $R: \alpha_1, \ldots, \alpha_n$</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Equality Propositions</th>
</tr>
</thead>
<tbody>
<tr>
<td>$\Gamma \vdash M: \alpha$ $\Gamma \vdash M': \alpha$</td>
</tr>
<tr>
<td>$\Gamma \vdash M =_\alpha M'$ prop</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Truth</th>
</tr>
</thead>
<tbody>
<tr>
<td>$\Gamma \vdash \text{true}$ prop</td>
</tr>
</tbody>
</table>

<table>
<thead>

<tr>
<td>$\Gamma \vdash \Phi &amp; \Psi$ prop</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Coproduct Propositions</th>
</tr>
</thead>
<tbody>
<tr>
<td>$\Gamma, x: \alpha \vdash \Phi(x)$ prop $\Gamma, y: \beta \vdash \Psi(y)$ prop $\Gamma \vdash C: \alpha + \beta$</td>
</tr>
<tr>
<td>$\Gamma \vdash (\Phi + \Psi)(C)$ prop</td>
</tr>
</tbody>
</table>
Universal Quantification Propositions

\[ \frac{\Gamma, x : \alpha \vdash \Phi(x) \text{ prop}}{\Gamma \vdash \forall_x(\Phi) \text{ prop}} \]

Universal Modality Propositions

\[ \frac{\Gamma, x : \alpha \vdash \Phi(x) \text{ prop} \quad \Gamma \vdash E : T\alpha}{\Gamma \vdash \Box(E, \Phi) \text{ prop}} \]

Existential Modality Propositions

\[ \frac{\Gamma, x : \alpha \vdash \Phi(x) \text{ prop} \quad \Gamma \vdash E : T\alpha}{\Gamma \vdash \Diamond(E, \Phi) \text{ prop}} \]

Remark 4.2.2 The usual rules for weakening of contexts, and substitution of raw terms for object level variables, are derivable from the above rules by simple structural induction.

Propositional Theories for FIX

Now that we have the propositional syntax for the FIX logical system, we present rules for deducing the validity of the propositions. These rules will be presented in a sequent natural deduction style. We will use a sequent in context as our basic judgement, which will take the form:

\[ \Gamma, \Lambda \vdash \Phi. \]

Here, \( \Lambda \) is a finite set of propositions. The intended meaning of a judgement is that one has a deduction of \( \Phi \) which involves a certain number of undischarged hypotheses, each of which must occur in the set \( \Lambda \). We shall write \( \Gamma, \Lambda, \Psi \vdash \Phi \) for \( \Gamma, \Lambda \cup \{\Psi\} \vdash \Phi \) and in the case that \( \Lambda \) is empty, we simply omit the symbol \( \Lambda \) from the judgement. A FIX theory, \( Th \), is specified by a FIX signature, together with a specific collection of sequents in context, which are called the axioms of \( Th \). The collection of theorems of \( Th \) consists of the least collection of sequents in context which contains the axioms of \( Th \), and is closed under the following rules:

Weakening

\[ \frac{\Gamma, \Lambda \vdash \Phi}{\Gamma', \Lambda \vdash \Phi} \quad \text{where} \quad \Gamma \subseteq \Gamma' \]

Identity

\[ \frac{\Gamma \vdash \Phi \text{ prop} \quad \Gamma \vdash \Lambda \text{ prop}}{\Gamma, \Lambda, \Phi \vdash \Phi} \quad \text{(id)} \]

62
Substitution
\[
\Gamma, x: \alpha, \Lambda(x) \vdash \Phi(x) \quad \Gamma \vdash M: \alpha \\
\quad \Gamma, \Lambda(M) \vdash \Phi(M) \quad \text{(sub)}
\]

Cut
\[
\Gamma, \Lambda \vdash \Phi \quad \Gamma, \Phi, \Lambda' \vdash \Psi \\
\quad \Gamma, \Lambda, \Lambda' \vdash \Psi \quad \text{(cut)}
\]

Equations
Every logical rule for deducing equations in FIX\(_=\) becomes a rule in the FIX logic, where judgements of the form \(\Gamma \vdash M = M' : \alpha\) become judgements of the form \(\Gamma \vdash M =_\alpha M'\).

Null Type Falsity Entailment
\[
x: \text{null} \vdash \text{false} \quad \text{(null)}
\]

Truth Entailment
\[
\Gamma \vdash \text{prop} \\
\quad \Gamma, \Lambda \vdash \text{true} \quad \text{(T)}
\]

Falsity Entailment
\[
\Gamma, \Lambda \vdash \text{false} \quad \Gamma \vdash \Phi \text{ prop} \\
\quad \Gamma, \Lambda \vdash \Phi \quad \text{(L)}
\]

Equality Entailment
\[
x: \alpha \vdash x =_\alpha x \\
\quad x: \alpha, x': \alpha, x =_\alpha x' \vdash x' =_\alpha x \quad \text{(sym)}
\]
\[
x: \alpha, x': \alpha, x =_\alpha x', x' =_\alpha x'' \vdash x =_\alpha x'' \quad \text{(tran)}
\]
\[
\Gamma, x: \alpha \vdash M(x) : \beta \\
\quad \Gamma, x: \alpha, x': \alpha, x =_\alpha x' \vdash M(x) =_\beta M(x') \quad \text{(sub1)}
\]
\[
\Gamma, x: \alpha \vdash \Phi(x) \text{ prop} \\
\quad \Gamma, x: \alpha, x': \alpha, x =_\alpha x', \Phi(x) \vdash \Phi(x') \quad \text{(sub2)}
\]
Conjunction Entailment
\[
\begin{align*}
\Gamma, \Lambda \vdash \Phi & \quad \Gamma, \Lambda \vdash \Psi \\
\Gamma, \Lambda \vdash \Phi & \quad \Gamma, \Lambda \vdash \Psi \\
\Gamma, \Lambda \vdash \Phi & \quad \Gamma, \Lambda \vdash \Psi \\
\Gamma, \Lambda \vdash \Phi & \quad \Gamma, \Lambda \vdash \Psi \\
\end{align*}
\]

Universal Quantification Entailment
\[
\begin{align*}
\Gamma, x : \alpha, \Lambda \vdash \phi(x) & \quad (\forall i) \\
\Gamma, \Lambda \vdash \forall_{\alpha}(\phi) & \quad (\forall e) \\
\Gamma, \Lambda \vdash \forall_{\alpha}(\phi) & \quad \Gamma \vdash M : \alpha \\
\Gamma, \Lambda \vdash \phi(M) & \quad (\forall e)
\end{align*}
\]

Universal Modality Entailment
\[
\begin{align*}
\Gamma, x : \alpha, \Lambda, \text{Val}(x) =_{\tau_{\alpha}} E \vdash \phi(x) & \quad (\Box i) \\
\Gamma, \Lambda \vdash \Box(E, \Phi) & \quad (\Box e) \\
\Gamma, \Lambda \vdash \Box(E, \Phi) & \quad \Gamma, \Lambda \vdash \text{Val}(M) =_{\tau_{\alpha}} E \\
\Gamma, \Lambda \vdash \Phi(M) & \quad (\Box e)
\end{align*}
\]

Existential Modality Entailment
\[
\begin{align*}
\Gamma, \Lambda \vdash \text{Val}(M) =_{\tau_{\alpha}} E & \quad \Gamma, \Lambda \vdash \Phi(M) \\
\Gamma, \Lambda \vdash \Diamond(E, \Phi) & \quad (\Diamond i) \\
\Gamma, x : \alpha, \Lambda, \text{Val}(x) =_{\tau_{\alpha}} E, \phi(x) \vdash \Psi & \quad \Gamma, \Lambda \vdash \Diamond(E, \Phi) \\
\Gamma, \Lambda \vdash \Psi & \quad (\Diamond e)
\end{align*}
\]

Coproduct Entailment
\[
\begin{align*}
\Gamma, \Lambda \vdash \phi(M) & \quad \Gamma, y : \beta \vdash \psi(y) \text{ prop} \\
\Gamma, \Lambda \vdash (\phi + \psi)(\text{lnr}(M)) & \quad (\ast i) \\
\Gamma, \Lambda \vdash (\phi + \psi)(\text{lnr}(N)) & \quad (\ast i) \\
\begin{align*}
\Gamma, \Lambda \vdash (\phi + \psi)(C) \\
\Gamma, x : \alpha, \Lambda, \text{lnr}(x) =_{\alpha + \beta} C, \phi(x) \vdash \Theta(F(x)) \\
\Gamma, y : \beta, \Lambda, \text{lnr}(y) =_{\alpha + \beta} C, \psi(y) \vdash \Theta(G(y)) \\
\Gamma, \Lambda \vdash \Theta(F, G)(C)
\end{align*}
\]

Disjoint Sum Condition
\[
\begin{align*}
\Gamma, \Lambda, \text{lnr}(M) =_{\alpha + \beta} \text{lnr}(N) \vdash \text{false} (\text{dsum})
\end{align*}
\]
Modality Condition
\[ \Gamma, \Lambda \vdash \text{Let}(E,F) =_{\sigma} \text{Val}(M) \]
\[ \Gamma, \Lambda \vdash \diamond(E,x.F(x) =_{\sigma} \text{Val}(M)) \quad \text{(mod)} \]

Nat Induction
\[ \Gamma, \Lambda \vdash \Phi(0) \quad \Gamma, n: \text{nat}, \Lambda, \Phi(n) \vdash \Phi(\text{Suc}(n)) \quad \Gamma \vdash N: \text{nat} \]
\[ \Gamma, \Lambda \vdash \Phi(N) \quad \text{(natin)} \]

Fix Induction
\[ \Gamma, e: \text{Fix}, \Lambda, \diamond(e, \Phi) \vdash \Phi(\sigma(e)) \quad \Gamma \vdash N: \text{fix} \]
\[ \Gamma, \Lambda \vdash \Phi(N) \quad \text{(fixin)} \]

This completes the rules for deriving sequents.

Informal Explanation of the FIX Propositions

The FIX logic has many features in common with intuitionistic predicate calculus; for the latter see [Dum77]. However, it introduces propositions of the form \( \square(e, \Phi) \), \( \diamond(e, \Phi) \), \( \Phi + \Psi \)(z), and so we shall describe informally the intended meaning of this syntax.

For the universal modality, \( \square(e, \Phi) \), the intended meaning is
\[ \forall x: \alpha.(\text{Val}(x) = e \triangleright \Phi(x)), \]
which we read as “for all \( x \) of type \( \alpha \), if it is the case that \( e \) is provably equal to the value of \( x \) then necessarily \( \Phi(x) \) holds.”

For the existential modality, \( \diamond(e, \Phi) \), the intended meaning is
\[ \exists x: \alpha.\text{Val}(x) = e \sqcap \Phi(x), \]
which we read as “it is possible that \( e \) is provably equal to \( \text{Val}(x) \) and that \( \Phi(x) \) holds.”

For coproduct propositions, \( \Phi + \Psi \)(z), the intended meaning is
\[ (\exists x: \alpha.\text{z} = \text{lnl}_\beta(x) \sqcap \Phi(x)) \lor (\exists y: \beta.\text{z} = \text{lnr}_\alpha(y) \sqcap \Psi(y)), \]
which we read as “it is either the case that \( z \) is provably equal to \( \text{lnl}_\beta(x) \) and that \( \Phi(x) \) holds, or it is the case that \( z \) is provably equal to \( \text{lnr}_\alpha(y) \) and that \( \Psi(y) \) holds.”

Remark 4.2.3 Each of the terms \( F^N(M) \) and \( \text{It}_\alpha(F, N) \) is unique up to provable equality in the FIX logic. In FIX it is necessary to impose rules which make uniqueness explicit. However, in the FIX logic, this uniqueness is derivable from

65
the rules for Nat and Fix Induction. Consider, for example, the uniqueness rule for
the fixpoint type. Set \( \Phi(n) \overset{\text{def}}{=} G(n) = \alpha \text{lt}(F, n) \) where \( n : \text{fix} \). Using the FIX rules
we may deduce that

\[
\begin{aligned}
& \Gamma, e : T \text{fix}, n : \text{fix}, \Lambda, e = \text{Val}(n), \\
& \quad \Box(e, \Phi) \vdash F(\text{Let}(\text{Val}(n), u.\text{Val}(G(u)))) = F(\text{Let}(\text{Val}(n), u.\text{Val}(\text{lt}(F, u))))
\end{aligned}
\]

and this implies \( \Gamma, e, \Lambda, \Box(e, \Phi) \vdash \Phi(\sigma(e)) \); we are done by \( (\text{fixin}) \).

4.3 Adjoint Style Formulation of the FIX Logic

The Adjoint Rules

The FIX logic can be presented using rules which are closely related to the cate-
gorical semantics given in Chapter 5. The new system is given by substituting the
following rules for their counterparts in the FIX logic.

**Equality Entailment**

\[
\frac{\Gamma, x : \alpha, x' : \alpha, \Lambda, x =_\alpha x' \vdash \Phi(x')}{\Gamma, x : \alpha, \Lambda \vdash \Phi(x)} (= \text{ad})
\]

**Conjunction Entailment**

\[
\frac{\Gamma, \Lambda \vdash \Phi \quad \Gamma, \Lambda \vdash \Psi}{\Gamma, \Lambda \vdash \Phi \& \Psi} (\& \text{ad})
\]

**Universal Quantification Entailment**

\[
\frac{\Gamma, x : \alpha, \Lambda \vdash \Phi(x)}{\Gamma, \Lambda \vdash \forall \alpha(\Phi)} (\forall \text{ad})
\]

**Universal Modality Entailment**

\[
\frac{\Gamma, x : \alpha, \Lambda(\text{Val}(x)) \vdash \Phi(x)}{\Gamma, e : T \alpha, \Lambda(e) \vdash \Box(e, \Phi)} (\Box \text{ad})
\]

**Existential Modality Entailment**

\[
\frac{\Gamma, x : \alpha, \Lambda(\text{Val}(x)), \Phi(x) \vdash \Psi(\text{Val}(x))}{\Gamma, e : T \alpha, \Lambda(e), \Diamond(e, \Phi) \vdash \Psi(e)} (\Diamond \text{ad})
\]

**Coproduct Entailment**

\[
\frac{\Gamma, x : \alpha, \Lambda(\text{ln}_{\alpha}(x)), \Phi(x) \vdash \Theta(F(x)) \quad \Gamma, y : \beta, \Lambda(\text{ln}_{\alpha}(y)), \Psi(y) \vdash \Theta(G(y))}{\Gamma, x : \alpha + \beta, \Lambda(x), (\Phi + \Psi)(x) \vdash \Theta([F, G](x))} (+ \text{ad})
\]

66
Equivalence of the Systems

Lemma 4.3.1. The following are derived rules in the FIX logic, where \( \Gamma \vdash M : \alpha \) is a FIX term in context:

\[
\frac{\Gamma, \Lambda \vdash \Phi(M)}{\Gamma, x, \Lambda, x = M \vdash \Phi(x)} \quad (ts) \quad \frac{\Gamma, \Lambda(M) \vdash \Phi}{\Gamma, x, \Lambda(x), x = M \vdash \Phi} \quad (es)
\]

Proof: We omit the proof of rule (ts); for rule (es), note that the backwards direction follows from (sub). For the forwards direction, it suffices to show the case when \( \Lambda \) is a single proposition. Indeed, we have:

\[
\frac{\Gamma, x \vdash \Theta(x) \quad (hyp)}{\Gamma, x, x', \Theta(x), x = x' \vdash \Theta(x')} \quad (sub2) \quad \frac{\Gamma, x, \Theta(x), x = M \vdash \Theta(M) \quad (sub)}{\Gamma, x, \Theta(x), x = M \vdash \Phi} \quad (cut) \quad \frac{\Gamma, x, \Theta(M) \vdash \Phi}{\Gamma, x, \Theta(x), x = M \vdash \Phi} \quad (hyp)
\]

\[\square\]

Theorem 4.3.2. The original FIX logic and the system defined on Page 66 are equivalent.

Proof: The proof of the equivalence for equality, conjunction and universal quantification is well known. We give details for the remaining forms of proposition: (Case (\( \Box i \))(\( \Box e \)) imply (\( \Box ad \))):

\[
\frac{\text{(hyp)}}{\Gamma, e, \Lambda(e) \vdash \Box (e, \Phi)}
\]

\[
\frac{\Gamma, x, e, \Lambda(e), e = \text{Val}(x) \vdash \Box (e, \Phi) \quad \Gamma, x, e, \Lambda(e), e = \text{Val}(x) \vdash e = \text{Val}(x)}{\Gamma, x, e, \Lambda(e), e = \text{Val}(x) \vdash \Phi(x)} \quad (\Box e)
\]

\[
\frac{\Gamma, x, \Lambda(\text{Val}(x)), \text{Val}(x) = \text{Val}(x) \vdash \Phi(x)}{\Gamma, x, \Lambda(\text{Val}(x)) \vdash \Phi(x)} \quad (\text{sub})
\]

\[
\frac{\Gamma, x, e, \Lambda(e), e = \text{Val}(x) \vdash \Phi(x)}{\Gamma, x, e, \Lambda(e), e = \text{Val}(x) \vdash \Phi(x)} \quad (es)
\]

\[
\frac{\Gamma, e, \Lambda(e) \vdash \Box (e, \Phi)}{\Gamma, e, \Lambda(e) \vdash \Box (e, \Phi)} \quad (\Box i)
\]

where (es) was established in Lemma 4.3.1.

67
(Case \(\Box \text{ad} \) implies \(\Box \text{e}(\Box \text{i})\)):

\[
\begin{align*}
\text{(hyp)} & \quad \Gamma, \Lambda \vdash \Box (E, \Phi) \\
\text{(ts)} & \quad \Gamma, e', \Lambda, e' = E \vdash \Box (e', \Phi) \\
\text{(ad)} & \quad \Gamma, x, \Lambda, \text{Val}(x) = E \vdash \Phi(x) \quad \text{(sub)} \quad \Gamma, \Lambda, \text{Val}(M) = E \vdash \Phi(M) \\
\text{(hyp)} & \quad \Gamma, \Lambda \vdash \Phi(M) \\
\text{(cut)}
\end{align*}
\]

\[
\begin{align*}
\text{(hyp)} & \quad \Gamma, x, \Lambda, \text{Val}(x) = E \vdash \Phi(x) \\
\text{(ad)} & \quad \Gamma, e, \Lambda, e = E \vdash \Box (e, \Phi) \\
\text{(hyp)} & \quad \Gamma, \Lambda \vdash \Box (E, \Phi)
\end{align*}
\]

(Case \(\Diamond \text{i}(\Diamond \text{e}) \) imply \(\Diamond \text{ad}\)):

\[
\begin{align*}
\text{(hyp)} & \quad \Gamma, x, \Lambda(\text{Val}(x)), \Phi(x) \vdash \Psi(\text{Val}(x)) \\
\Gamma, e, x, \Lambda(e), \Phi(x), e = \text{Val}(x) \vdash \Psi(e) \\
\text{(hyp)} & \quad \Gamma, e, \Lambda(e), \Diamond(e, \Phi) \vdash \Diamond(e, \Phi) \\
\Gamma, e, \Lambda(e), \Diamond(e, \Phi) \vdash \Psi(e)
\end{align*}
\]

where the last rule is \(\Diamond \text{e}\).

\[
\begin{align*}
\Gamma, e, x, \Lambda(e), \Phi(x), \text{Val}(x) = e \vdash \Diamond(e, \Phi) \\
\text{id)(i)} & \quad \Gamma, x, e, \Lambda(e), \Diamond(e, \Phi) \vdash \Psi(e) \\
\Gamma, e, x, \Lambda(e), \Phi(x), \text{Val}(x) = e \vdash \Psi(e) \\
\Gamma, x, \Lambda(\text{Val}(x)), \Phi(x) \vdash \Psi(\text{Val}(x))
\end{align*}
\]

(Case \(\Diamond \text{ad} \) implies \(\Diamond \text{i}(\Diamond \text{e})\)):

\[
\begin{align*}
\text{(hyp)} & \quad \Gamma, x, \Lambda, E = \text{Val}(x), \Phi(x) \vdash \Psi \\
\text{(id)} & \quad \Gamma, e, \Lambda, e = e, \Diamond(e, \Phi) \vdash \Psi(e) \\
\text{(hyp)} & \quad \Gamma, \Lambda \vdash \Diamond(e, \Phi) \\
\text{(id)} & \quad \Gamma, \Lambda \vdash \Diamond(E, \Phi)
\end{align*}
\]

\(\Gamma, \Lambda \vdash \Psi\)

68
\[
\frac{\Gamma, e, \Lambda, \Diamond(e, \Phi) \vdash \Diamond(e, \Phi) \quad (\text{hyp})}{\Gamma, \Lambda \vdash (\Phi(M) \quad (\text{hyp})}
\]
\[
\frac{\Gamma, x, \Lambda, \Phi(x) \vdash \Diamond(\text{Val}(x), \Phi) \quad (\text{ad})}{\Gamma, x, \Lambda, x = M \vdash \Phi(x) \quad (\text{ts})}
\]
\[
\frac{\Gamma, x, \Lambda, x = M \vdash \Diamond(\text{Val}(x), \Phi) \quad (\text{ts})}{\Gamma, \Lambda \vdash \Diamond(\text{Val}(M), \Phi)}
\]

and the result follows using \( \Gamma, \Lambda \vdash E = \text{Val}(M) \).

(Case (+i)(+e) imply (+ad)):

\[
\frac{\Gamma, z, x, \Lambda(\text{ln}(x)), \Phi(x) \vdash \Theta(F(x)) \quad (\text{hyp})}{\Gamma, z, x, \Lambda(z), z = \text{ln}(x), \Phi(x) \vdash \Theta(F(x)) \quad (\text{hyp})}
\]
\[
\{
\Gamma, z, x, \Lambda(z),
\begin{align*}
(\Phi + \Psi)(z), & \quad z = \text{ln}(x), \Phi(x) \vdash \Theta(F(x)) \\
\text{and similarly for } G
\end{align*}
\} \quad \{
\Gamma, z, \Lambda(z),
\begin{align*}
(\Phi + \Psi)(z) & \vdash (\Phi + \Psi)(z) \\
(\Phi + \Psi)(z) & \vdash (\Phi + \Psi)(z)
\end{align*}
\}
\]

where the final rule is (+e).

\[
\frac{\Gamma, z, \Lambda(z), (\Phi + \Psi)(z) \vdash \Theta(\{F, G\}(z)) \quad (\text{hyp})}{\Gamma, x, \Lambda(\text{ln}(x)), (\Phi + \Psi)(\text{ln}(x)) \vdash \Theta(F(x)) \quad (\text{hyp})}
\]
\[
\{
\Gamma, z, \Lambda(z),
\begin{align*}
(\Phi + \Psi)(z) & \vdash (\Phi + \Psi)(z) \\
\Phi(x) & \vdash (\Phi + \Psi)(\text{ln}(x))
\end{align*}
\} \quad \{
\Gamma, x, \Lambda(\text{ln}(x)),
\begin{align*}
\Phi(x) & \vdash (\Phi + \Psi)(\text{ln}(x))
\end{align*}
\}
\]

(Case (+ad) implies (+i)(+e)):

\[
\frac{\Gamma, z, \Lambda, (\Phi + \Psi)(z) \vdash (\Phi + \Psi)(z) \quad (\text{ad})}{\Gamma, x, \Lambda, \Phi(x) \vdash (\Phi + \Psi)(\text{ln}(x)) \quad (\text{hyp})}
\]
\[
\frac{\Gamma, \Lambda, \Phi(M) \vdash (\Phi + \Psi)(\text{ln}(M)) \quad (\text{hyp})}{\Gamma, \Lambda \vdash (\Phi + \Psi)(\text{ln}(M))}
\]

\[
\frac{\Gamma, x, \Lambda, \text{ln}(x) = C, \Phi(x) \vdash \Theta(F(x)) \quad (\text{ad})}{\Gamma, z, \Lambda, z = C, (\Phi + \Psi)(z) \vdash \Theta(\{F, G\}(z)) \quad (\text{hyp})}
\]
\[
\frac{\Gamma, \Lambda, (\Phi + \Psi)(C) \vdash \Theta(\{F, G\}(C)) \quad (\text{hyp})}{\Gamma, \Lambda \vdash \Theta(\{F, G\}(C))}
\]

\qed
4.4 Extensions of FIX

Some Inconsistent Extensions of the FIX Logic

The induction rule for \textit{nat} is just the usual principle of mathematical induction. The induction rule for \textit{fix} can be rendered informally as: to prove that a property \( \Phi(n) \) holds of all elements \( n \) in \textit{fix}, it is sufficient to prove for all computations \( e \) of an element of \textit{fix} that \( \Phi(\sigma(e)) \) holds if whenever \( e \) evaluates to a value, that value satisfies \( \Phi(x) \). This principle is consistent (see Section 5.1) but only because the FIX propositions have limited forms. In fact, extending the FIX logic with unrestricted intuitionistic negation, implication or existential quantification renders it inconsistent.

**Proposition 4.4.1** Extending the FIX logic with intuitionistic implication renders the system inconsistent.

**Proof** Since FIX contains falsity (false), adding implication \((\Phi \supset \Psi)\) means that one also has negation \((\neg \Phi \equiv (\Phi \supset \text{false}))\). So consider the proposition

\[
\Phi(n) \stackrel{\text{def}}{=} \neg(\sigma(\omega) = n)
\]

about \( n: \text{fix} \). From (ts) we can deduce that \( \Gamma, e: T \text{fix}, \Lambda, \Box(e, \Phi), \omega = e \vdash \Box(\omega, \Phi) \) and using Proposition 4.5.1 we see that \( \Gamma, \Lambda, \Box(\text{Val}(\sigma(\omega)), \Phi) \vdash \Phi(\sigma(\omega)) \). Recalling that \( \omega \) is provably equal to \text{Val}(\sigma(\omega)) together with the rules for intuitionistic implication it is easy to see that

\[
\Gamma, e: T \text{fix}, \Lambda, \Box(e, \Phi), \omega = e, \sigma(\omega) = \sigma(\omega) \vdash \text{false}.
\]

But the structure map of any initial \( T \) algebra is an isomorphism, which means that in FIX we have \( \Gamma, e, \Lambda, \sigma(\omega) = \sigma(e) \vdash \omega = e \). Hence

\[
\Gamma, e: T \text{fix}, \Lambda, \Box(e, \Phi), \sigma(\omega) = \sigma(e) \vdash \text{false}
\]

and applying (fixin) we have \( \Gamma, n: \text{fix}, \Lambda \vdash \Phi(n) \).

So the induction principle for \textit{fix} entails that \( \Phi(n) \) holds of all \( n \in \text{fix} \), and in particular of \( \sigma(\omega) \), which is a contradiction. \( \square \)

**Proposition 4.4.2** Extending the FIX logic with intuitionistic existential quantification renders the system inconsistent.

**Proof** This proof mimics the ideas which show that the category \( \omega \text{Cpo} \) together with inclusive subsets does not model standard intuitionistic predicate calculus [Dum77]. Recall that in \( \omega \text{Cpo} \), Beck Chevalley conditions fail for left adjoints to projections; for if this is not the case we can deduce that such left adjoints take inclusive subsets to inclusive subsets by unravelling Beck Chevalley at a global element in \( \omega \text{Cpo} \). Then considering the \( \omega \text{Cpo} \ \mathbb{N} \times \Omega \) and inclusive subset

\[
\{(m, n) \mid m \in \mathbb{N} \& n \in \Omega \setminus \{\top\} \& n \leq m\}
\]

70
we can deduce that \( \{ n \mid n \in \Omega \setminus \{ \top \} \} \) is inclusive in \( \Omega \). This is not so.

Consider the term \( \bot \overset{\text{def}}{=} \text{it}_{T \text{fix}}(e. \text{let} (e, x \cdot x), \sigma(\omega)) ; T \text{fix} \) (recall the discussion of domain theoretic properties of FIX on Page 48). Set

\[
\Phi(n) \overset{\text{def}}{=} \exists_{nat}(m. (u. \sigma(\text{Val}(u)))^m(\sigma(\bot))) =_{\text{fix}} n.
\]

Using the usual rules for intuitionistic existential quantification together with the FIX rules we may deduce \( e, n, e = \text{Val}(n), \Box(e, \Phi) \vdash \Phi(n) \vdash \Phi(\sigma(\text{Val}(n))) \) and from \( \text{fixin} \) we have \( n: \text{fix} \vdash \Phi(n) \). In particular this means that

\[
\vdash \exists_{nat}(m. (u. \sigma(\text{Val}(u)))^m(\sigma(\bot))) =_{\text{fix}} \sigma(\omega).
\]

Using \( \text{mono} \) and that \( \sigma \) is an isomorphism we conclude \( \vdash \bot = \omega \). \qed

4.5 Further Results about the FIX Logic

The Modality Conditions

We state and prove a proposition which we shall make use of in Chapter 5 where it will be used in establishing a categorical logic correspondence for the FIX logic.

**Proposition 4.5.1** Within the FIX logical system, the following birules are derivable:

\[
\frac{\Gamma, \Lambda \vdash \Phi(M)}{\Gamma, \Lambda \vdash \Box(\text{Val}(M), \Phi)} \\
\frac{\Gamma, \Lambda \vdash \Phi(M) \quad \Gamma, y: \beta, \Lambda \vdash \Psi(y) \text{ prop}}{\Gamma, \Lambda \vdash (\Phi + \Psi)(\text{ln}_n(M))} \\
\frac{\Gamma, \Lambda \vdash \Psi(N) \quad \Gamma, x: \alpha, \Lambda \vdash \Phi(x) \text{ prop}}{\Gamma, \Lambda \vdash (\Phi + \Psi)(\text{ln}_\beta(N))}
\]

**Proof** The forward directions of each of these birules are easy to see and thus we omit the details. We shall give details of the backwards directions for the existential modality and coproduct.

First, the existential modality. We have

\[
\frac{\text{(mono)(cut)}}{\Gamma, x, y, \Lambda, \text{Val}(x) = \text{Val}(y), \Phi(x) \vdash \Phi(y)} \\
\frac{\text{\Diamond ad}}{\Gamma, e, y, \Lambda, e = \text{Val}(y), \Diamond(e, \Phi) \vdash \Phi(y)} \\
\frac{\text{\Diamond sub}}{\Gamma, y, \Lambda, \Diamond(\text{Val}(y), \Phi) \vdash \Phi(y)}
\]

from which the result is immediate. Now we move to the coproduct.
We have
\[
\begin{align*}
\frac{}{\Gamma, \Lambda \vdash (\Phi + \Psi)(\text{lnl}(M))} \\
\frac{}{(\text{id})} \quad \frac{}{\Gamma, x, \Lambda, \text{lnl}(x) = \text{lnl}(M), \Phi(x) \vdash \Phi((u.u)(x))} \\
\frac{}{(\text{djsim})(\perp)} \\
\frac{}{\Gamma, \Lambda \vdash \Phi((\{u.u, v.M\}(\text{lnl}(M))))} \\
\end{align*}
\]
and the result follows from the rules for Coproduct Equations. \qed

**Frobenius Reciprocity for the FIX Logic**

To prove a Frobenius Reciprocity style rule for the FIX logic, it is convenient to use the next lemma:

**Lemma 4.5.2** In the FIX logic, if $\Gamma, \Lambda, \Phi \vdash \Psi$, then
\[
\Gamma, e, \Lambda \vdash \Diamond(e, y, \Phi) \vdash \Diamond(e, y, \Psi).
\]

**Proof** Use $(\Diamond \text{ad})$ and $(\text{sub})$. \qed

**Proposition 4.5.3** Within the fix logical system, the following birule is derivable:
\[
\begin{align*}
\frac{}{\Gamma, e, x, \Lambda \vdash \Diamond(e, y, \Phi(x, \text{Val}(y)) \& \Psi(x, y))} \\
\end{align*}
\]

**Proof** First we prove the forwards direction. From the hypothesis, Lemma 4.5.2, and the rules $(\& \text{ad})$ for conjunction, we deduce\(^1\)
\[
\Diamond(e, y, \Phi(x, \text{Val}(y)) \& \Psi(x, y)) \vdash \Diamond(e, y, \Phi(x, \text{Val}(y))) \& \Diamond(e, y, \Psi(x, y)).
\]

Also, we have
\[
\begin{align*}
\frac{}{(\text{id})(= \text{ad})(\text{sub})} \\
\frac{}{(\text{id})} \\
\frac{}{(\Diamond \text{e})}
\end{align*}
\]
and the result is immediate from the rules $(\& \text{ad})$.

For the backwards direction, note that using $(\Diamond \text{i})$ we have
\[
\Phi(x, e), \Psi(x, y), \text{Val}(y) = e \vdash \Diamond(e, y, \Phi(x, \text{Val}(y)) \& \Psi(x, y));
\]

\(^1\)For sake of space we omit contexts in this proof.
label this sequent (*). Hence

\[ \Phi(x, e), \Diamond(e, y, \Psi(x, y)) \vdash \Diamond(e, y, \Psi(x, y)) \]

and from (\&ad) and (cut) we are done. \qed

The Existence and Disjunction Properties

We now give two results which witness the constructive nature of the FIX logic. They bear some resemblance to the existence and disjunction properties of standard intuitionistic logic [LS80], [Pit89].

Theorem 4.5.4 ["Existence Property"] If \( E \) is a closed term of type \( T\alpha \), then \( \vdash \Diamond(e, \Phi) \) is derivable in FIX if and only if there is a closed term \( M \) of type \( \alpha \) for which \( \vdash E =_{T\alpha} \text{Val}(M) \) and \( \vdash \Phi(M) \) are derivable. (In other words, a formal proof that \( E \) evaluates to a value satisfying \( \Phi(x) \) necessitates the existence of a term denoting that value.)

Theorem 4.5.5 ["Disjunction Property"] If \( E \) is a closed term of coproduct type \( \alpha + \beta \), \( \Phi(x) \) and \( \Psi(y) \) are properties of \( \alpha \) and \( \beta \) and \( \vdash (\Phi + \Psi)(E) \) is derivable in FIX, then either \( \vdash E =_{\alpha + \beta} \text{lnl}(M) \) and \( \vdash \Phi(M) \) are derivable for some closed term \( M \) of type \( \alpha \), or \( \vdash E =_{\alpha + \beta} \text{lnr}(N) \) and \( \vdash \Psi(N) \) are derivable for some closed term \( N \) of type \( \beta \).

Standardness of the Natural Number Type

The Existence Property enables one to produce closed terms of type nat from a computation of a number (i.e. a closed term of type \( T\text{nat} \)) together with a proof that the computation converges. There remains the possibility that a closed term of type nat is not a value, i.e. a standard numeral. However, this is not so:

Theorem 4.5.6 ["Standardness of nat"] Every closed term of type nat in FIX is provably equal to a standard numeral Suc\(^n\)(O).

Theorems 4.5.4, 4.5.5 and 4.5.6 will be proved in Chapter 5.

Miscellaneous Results

Lemma 4.5.7 Modulo the remaining rules of the FIX logic, the modality condition

\[ \Gamma, \Lambda \vdash \text{Let}(E, F) =_{T\alpha} \text{Val}(M) \]

\[ \Gamma, \Lambda \vdash \Diamond(E, x.F(x) =_{T\alpha} \text{Val}(M)) \]

(mod)
is equivalent to the rule

\[
\Gamma, \Lambda \vdash \Box(E, x. \Box(F(x), \Phi)) \quad \frac{\text{(mod')}}{\Gamma, \Lambda \vdash \Box(\text{Let}(E, F), \Phi)}
\]

**Proof** (*Case (mod) implies (mod’)*): Applying (\(\Box e\)) twice to the hypothesis of (mod’) we have

\[
\Gamma, y, x, \Lambda, E = \text{Val}(x), F(x) = \text{Val}(y) \vdash \Phi(y)
\]

and using (mod) we obtain

\[
\Gamma, y, \Lambda, \text{Let}(E, F) = \text{Val}(y) \vdash \Box(E, x.F(x) = \text{Val}(y)).
\]

By a suitable weakening of the hypotheses of the above derived judgements, we can apply (\(\Box e\)) and (\(\Box i\)) to obtain the result.

(*Case (mod’) implies (mod))*: As this direction is not entirely straightforward we give a full proof tree:

\[
\begin{align*}
\Gamma, x, y, \Lambda, E = \text{Val}(x), F(x) = \text{Val}(y) & \vdash E = \text{Val}(x) \quad \text{(id)} \\
\Gamma, x, y, \Lambda, E = \text{Val}(x), F(x) = \text{Val}(y) & \vdash F(x) = \text{Val}(y) \quad \text{(id)} \\
\Gamma, x, y, \Lambda, E = \text{Val}(x), F(x) = \text{Val}(y) & \vdash \Box(E, u.F(u) = \text{Val}(y)) \quad \text{(\(\Box i\))} \\
\Gamma, \Lambda & \vdash \Box(E, x. \Box(F(x), y. \Box(E, u.F(u) = \text{Val}(y)))) \quad \text{(\(\Box i\))} \\
\Gamma, \Lambda & \vdash \Box(\text{Let}(E, F), y. \Box(E, u.F(u) = \text{Val}(y))) \quad \text{(mod’)}
\end{align*}
\]

Using this conclusion together with the premiss of (mod) as the premisses for (\(\Box e\)) completes the proof.

**Lemma 4.5.8** Modulo the remaining rules of the FIX logic, the rule

\[
\Gamma, \Lambda \vdash \text{Val}(M) = \text{Val}(M') \quad \frac{\text{(mono)}}{\Gamma, \Lambda \vdash M = M'}
\]

is equivalent to the rule

\[
\Gamma, \Lambda \vdash \Phi(M) \quad \frac{\text{\text{(mono')}}}{\Gamma, \Lambda \vdash \Box(\text{Val}(M), \Phi)}
\]

**Proof** We sketch the details.

(*Case (mono) implies (mono’)*): The rule (mono) yields

\[
\Gamma, x, \Lambda, \text{Val}(M) = \text{Val}(x) \vdash M = x.
\]

Applying (\(\text{ts}\)) to the hypothesis of (mono’), cutting (\(\text{cut}\)) and using (\(\Box i\)) we are done.

(*Case (mono’) implies (mono)*): The rule (mono’) yields

\[
\Gamma, \Lambda \vdash \Box(\text{Val}(M), x.x = M).
\]

Now apply (\(\Box e\)) to this along with the hypothesis of (mono).

\[\square\]
Chapter 5

Categorical Semantics of the FIX Logic

5.1 FIX Hyperdoctrines

For background on hyperdoctrines and indexed categories see [JP78], [See83] and [Pit89].

Definition 5.1.1 A FIX hyperdoctrine is specified by a FIX category $\mathcal{C}$ (referred to as the base category) together with a $\mathcal{C}$ indexed poset, $\mathcal{C}:\mathcal{C}^{\text{op}} \rightarrow \mathbf{Poset}$, where if $f: A \rightarrow B$ is a morphism in the base category $\mathcal{C}$ we denote the corresponding pullback function by $f^*: \mathcal{C}(B) \rightarrow \mathcal{C}(A)$ with the fibre at $A$ denoted by $\mathcal{C}(A)$. We adopt the following notational convention. If

\[
\begin{array}{ccc}
A & \xrightarrow{f} & B \\
g & & h \\
\downarrow & & \downarrow \\
C & \xrightarrow{k} & D
\end{array}
\]

is a commuting square in $\mathcal{C}$ then right Beck-Chevalley conditions are said to hold (which will be abbreviated to RBC) if $f^*: \mathcal{C}(B) \rightarrow \mathcal{C}(A)$ and $k^*: \mathcal{C}(D) \rightarrow \mathcal{C}(C)$ have right adjoints which satisfy the identity $\forall f \circ g^* = h^* \circ k$. We use a dual convention for left Beck-Chevalley conditions, LBC. The indexed poset satisfies the following conditions:

1. The fibres are meet semi-lattices with least element, and the fibre over the initial object is a singleton. The top element is denoted by $\top$, the bottom element by $\bot$, and the meet of elements $x \in \mathcal{C}(A)$ and $y \in \mathcal{C}(A)$ by $x \wedge y \in \mathcal{C}(A)$. The pullback functions preserve meets, top and bottom elements.

2. RBC holds for all squares of the form

\[
\begin{array}{ccc}
\mathcal{C} \times A & \xrightarrow{\pi} & \mathcal{C} \\
\downarrow \quad f \times \text{id} & & \downarrow f \\
\mathcal{C}' \times A & \xrightarrow{\pi'} & \mathcal{C}'
\end{array}
\]
where the morphisms \( \pi \) and \( \pi' \) are product projections.

3. RBC and LBC hold for all squares of the form

\[
\begin{array}{c}
\begin{array}{c}
C \times A \xrightarrow{id \times \eta} C \times TA \\
f \times id \downarrow \quad f \times id
\end{array} \\
\begin{array}{c}
C' \times A \xrightarrow{id \times \eta} C' \times TA
\end{array}
\end{array}
\]

Also, the hyperdoctrine enjoys a form of Frobenius Reciprocity, namely given \( x \in C(C \times TA) \) and \( y \in C(C \times A) \) we have

\[ \exists (id \times \eta)((id \times \eta)^*(x) \land y) = x \land \exists (id \times \eta)(y). \]

These conditions ensure the soundness of the rules for Universal and Existential Modality Entailment.

4. There is an operation \( + \) on fibres

\[ + : C(C \times A) \times C(C \times B) \rightarrow C(C \times (A + B)) \]

which is natural in \( C \). Suppose we are given elements

\[
\begin{align*}
x & \in C(C \times A) \quad u \in C(C \times (A + B)) \\
y & \in C(C \times B) \quad z \in C(C \times D)
\end{align*}
\]

and morphisms \( f : C \times A \rightarrow D \), \( g : C \times B \rightarrow D \). Then we demand that

\[
\frac{(id_C \times i)^*(u) \land x \leq (\pi_A, f)^*(z)}{u \land (x + y) \leq (\pi, \{f, g\})^*(z)}
\]

where \( i : A \rightarrow (A + B) \) and \( j : B \rightarrow (A + B) \) are coproduct insertions,

\[
(C \times A) + (C \times B) \xrightarrow{\phi} C \times (A + B)
\]

is the obvious isomorphism and

\[
\pi_A : C \times A \rightarrow C \quad \pi_B : C \times B \rightarrow C \quad \pi : C \times (A + B) \rightarrow C
\]

are product projections. Finally, \( \{f, g\} \overset{\text{def}}{=} [f, g] \circ \phi^{-1} \) where \([f, g]\) arises from the coproduct structure of \( C \). Note that if \( x + y \) exists, it is determined uniquely. These requirements ensure the soundness of the rules for Coproduct Entailment.
5. LBC holds for

\[
\begin{array}{c}
C \times A \\
\xrightarrow{id \times \Delta}
\end{array}
\]

The left adjoint to \(id \times \Delta\) satisfies the following Frobenius Reciprocity condition,

\[
\exists(id \times \Delta) \circ (id \times \Delta)^*(x) = x \land \exists(id \times \Delta) \circ \pi_C^*(\top)
\]

where \(x \in C(C \times A \times A)\) and \(\pi_C: C \times A \to C\). (Recall that the pullback function \(\pi_C^*\) preserves the top element by definition.) These conditions ensure the soundness of the rules for Equality Entailment.

6. We demand the inequalities

\[
(\eta \times \eta)^* \circ \exists \Delta(\top_{TA}) \leq \exists \Delta(\top_A)
\]

and

\[
(i, j)^* \circ \exists \Delta(\top_{A+B}) = \bot
\]

where \(\top_A \in C(A)\), \(\top_{TA} \in C(TA)\) and \(\top_{A+B} \in C(A + B)\) are the top elements of the fibres and \(i: A \to (A + B), j: B \to (A + B)\) are coproduct insertions. This guarantees the soundness of the Mono Condition and the Disjoint Sum Condition.

7. Given a morphism \(f: C \times TA \times B \times A \to TB\) then we demand the inequality

\[
\langle \text{lift}(f), \eta \pi_1 \rangle^* \circ \exists \Delta(\top) \leq \exists(id \times \eta) \circ \langle f, \eta \pi_2 \rangle^* \circ \exists \Delta(\top)
\]

where \(\top \in C(TA)\) is the top element of the fibre and

\[
\pi_1: C \times TA \times B \times TA \to B \quad \pi_2: C \times TA \times B \times A \to B
\]

are product projections. This ensures the soundness of the Modality Condition.

Finally, to complete the definition of a FIX hyperdoctrine, there are two fibrewise induction conditions and a coherence condition. The induction conditions ensure soundness of the induction rules in the logic and the coherence condition guarantees that semantic equality of terms coincides with derivable equality in the FIX logic.

8. Given elements \(x \in C(C), y \in C(C \times N)\) then we demand that

\[
\frac{x \leq (id, 0o !)^*(y)}{\pi^*(x) \land y \leq (id \times s)^*(y)}\]

where \(\pi: C \times N \to C\) is a product projection and \(0:1 \to N, s:N \to N\) are given as part of the structure of the NNO in the base category.
9. Given elements $x \in \mathcal{C}(C)$, $y \in \mathcal{C}(C \times \Omega)$ then we demand that

$$\pi^*(x) \land \forall (id \times \eta)(y) \leq (id \times \sigma)^*(y)$$

$$\pi'^*(x) \leq y$$

where $\pi: C \times T\Omega \to C$, $\pi': C \times \Omega \to C$ are product projections and $\sigma: T\Omega \to \Omega$ is given as part of the structure of the FPO in the base category.

10. Given morphisms $f, g: B \to A$ and the diagonal $\Delta: A \to A \times A$, then we ask that

$$\langle f, g \rangle^* \circ \exists \Delta(\top) = \top$$

$$f = g \text{ in } \mathcal{C}$$

This completes Definition 5.1.1. A morphism of FIX hyperdoctrines $\mathcal{C}$ and $\mathcal{C}'$ is specified by a FIX category morphism between the base categories (referred to as the base functor) say $F: \mathcal{C} \to \mathcal{C}'$, together with an indexed collection of monotone functions, called fibre morphisms, $F_A: \mathcal{C}(A) \to \mathcal{C'}(FA)$ for each object $A$ in $\mathcal{C}$. These monotone functions are required to preserve the structure of the fibres in a canonical fashion. For example, the pullback functions are preserved by the fibre morphisms in the sense that given a morphism $f: A \to B$ in $\mathcal{C}$, the following square commutes

$$\begin{array}{ccc}
C(A) & \xrightarrow{F_A} & \mathcal{C'}(FA) \\
\uparrow f^* & & \uparrow (F(f))^* \\
C(B) & \xrightarrow{F_B} & \mathcal{C'}(FB)
\end{array}$$

Also, the structure of the fibres is preserved by the fibre morphisms; for example

- Given $\top \in \mathcal{C}(A)$, then $F_A(\top) = \top \in \mathcal{C'}(FA)$,
- given $x, y \in \mathcal{C}(A)$, then $F_A(x \land y) = F_A(x) \land F_A(y)$, and
- given $x \in \mathcal{C}(C \times A)$ and $y \in \mathcal{C}(C \times B)$ then

$$F_{C \times (A+B)}(x + y) = F_{C \times A}(x) + F_{C \times B}(y).$$

The remaining structure of the fibres is preserved in a similar way; the details are omitted.

**The FIX Hyperdoctrine $\omega\mathcal{C}_{po}$**

The definition of a FIX hyperdoctrine is quite involved and so we must give a concrete example. We have the
Proposition 5.1.2 Recall that the category $\omega Cpo$ is a FIX category. There is an $\omega Cpo$ indexed poset, $I: \omega Cpo^{op} \rightarrow Poset$, where $I$ takes an $\omega Cpo$ $D$ to the set of inclusive subsets of $D$ which are ordered by inclusion and $I$ takes each continuous function $f: D \rightarrow D'$ to its inverse image function $f^{-1}$ restricted to inclusive subsets. This gives rise to a FIX hyperdoctrine.

Proof It is trivial to check that $f^{-1}: I(D') \rightarrow I(D)$ is well defined and indeed monotone and that $I$ is a functor. We define the operations that make $\omega Cpo$ a FIX hyperdoctrine, but omit detailed verifications.

1. With meet given by intersection of inclusive subsets, it is clear that each fibre is a meet semi-lattice with least element. It is easy to see that each pullback function is a morphism of pointed meet semi-lattices. Finally $I(\emptyset) = \{\emptyset\}$ is a singleton.

2. The right adjoint to projection is given by restriction of the dual image functions to inclusive subsets; that RBC holds is trivial.

3. The existence of left adjoints is well known, given by restriction of the set theoretic direct image functions to inclusive subsets. The right adjoint to

$$(id \times i)^{-1}: I(C \times D_+) \rightarrow I(C \times D)$$

is given by

$$\forall (id \times i)(I) \text{ def } (id \times i)(I) \cup \{(c, \bot) \mid c \in C\}$$

where $I \in I(C \times D)$. It is easy to see that this is a good definition and yields the required adjoint. Checking RBC and LBC is easy; Frobenius Reciprocity is virtually immediate.

4. Let $i: D \rightarrow D + D'$ and $j: D' \rightarrow D + D'$ be coproduct insertions. Given elements $I \in I(C \times D)$ and $J \in I(C \times D')$ we define

$$+ : I(C \times D) \times I(C \times D') \rightarrow I(C \times (D + D'))$$

by

$$I + J \text{ def } \exists (id \times i)(I) \cup \exists (id \times j)(J).$$

Note that the fibrewise induction conditions are satisfied because any inclusive subset of an $\omega Cpo$ is an $\omega Cpo$. Finally note that the existence of this concrete model implies the consistency of the pure FIX logic relative to Zermelo Fraenkel set theory.

\[\square\]

5.2 Categorical Semantics of FIX

Structures for FIX Signatures

Let $C$ be a FIX hyperdoctrine and $Sg$ a FIX signature. Then a structure, $M$, in $C$ is specified by the following data:

79
• A structure in the base FIX category $C$ (see Section 3.2), and

• for each basic relation symbol $R: \alpha_1, \ldots, \alpha_n$ an element $[R]$ in the fibre over $[\alpha_1] \times \ldots \times [\alpha_n]$.

**Interpretation of the FIX Propositions in Context**

Given a structure $M$ we now show how to interpret the FIX logic in a FIX hyperdoctrine. The propositions of FIX are modelled by elements in the fibres of the hyperdoctrine; more precisely, for each context $\Gamma$ and proposition $\Phi$ for which we can derive $\Gamma \vdash \Phi$ prop, we specify an element $[\Gamma.\Phi]$ of the fibre $C([\Gamma])$. If $\Gamma$ is empty we write $[\emptyset]$ for this. The semantics of propositions in context is defined using the structure of the propositions:

- $[\Gamma.\text{true}] \stackrel{\text{def}}{=} \top \in C([\Gamma])$.
- $[\Gamma.\text{false}] \stackrel{\text{def}}{=} \bot \in C([\Gamma])$.
- $[\Gamma.M =_\alpha N] \stackrel{\text{def}}{=} ([\Gamma.M], [\Gamma.N])^* \circ \exists \Delta(\top)$.
- $[\Gamma.\Phi \& \Psi] \stackrel{\text{def}}{=} [\Gamma.\Phi] \wedge [\Gamma.\Psi]$.
- $[\Gamma.\forall_\alpha(\Phi)] \stackrel{\text{def}}{=} \forall \pi_1([\Gamma, x: \alpha.\Phi])$.
- $[\Gamma.\Box(E, \Phi)] \stackrel{\text{def}}{=} (id, [\Gamma.E])^* \circ \forall(id \times \eta)([\Gamma, x: \alpha.\Phi(x)])$.
- $[\Gamma.\Diamond(E, \Phi)] \stackrel{\text{def}}{=} (id, [\Gamma.E])^* \circ \exists(id \times \eta)([\Gamma, x: \alpha.\Phi(x)])$.
- $[\Gamma.(\Phi + \Psi)(C)] \stackrel{\text{def}}{=} (id, [\Gamma.C])^*([\Gamma, x: \alpha.\Phi(x)] + [\Gamma, y: \beta.\Psi(y)])$.

**Models of FIX Theories**

If $\Lambda$ is a finite set of propositions, each of which is well formed in the context $\Gamma$, then set

$[\Gamma.\Lambda] \stackrel{\text{def}}{=} \bigwedge_{\Theta \in \Lambda} [\Gamma.\Theta]$.

A structure $M$ in a FIX hyperdoctrine $C$ satisfies a sequent in context $\Gamma, \Lambda \vdash \Phi$ if $[\Gamma.\Lambda] \leq [\Gamma.\Phi]$ holds in the fibre $C([\Gamma])$. Given a FIX theory, $Th$, then $M$ is called a model of the theory if it satisfies all the axioms of $Th$.

**The Substitution Lemma**

The next lemma tells us how substitution of terms for variables in propositions is modelled.
Lemma 5.2.1 Put $\Gamma' = [x_1: \alpha_1, \ldots, x_n: \alpha_n]$, let $\Gamma' \vdash \Phi(x_1, \ldots, x_n)$ prop be a FIX proposition in context and let $\Gamma \vdash M_i: \alpha_i$ for $i = 1, \ldots, n$ be FIX terms in context. Then

$$\llbracket \Gamma. \Phi(M) \rrbracket = (\llbracket \Gamma. M_1 \rrbracket, \ldots, \llbracket \Gamma. M_n \rrbracket)^*(\llbracket \Gamma'. \Phi(\bar{x}) \rrbracket).$$

Proof The proof proceeds by induction on the structure of propositions; we illustrate with $\Box_{(E, \Phi)}$ and $(\Phi + \Psi)(C)$.

\[
\begin{align*}
\llbracket \Gamma. \Box (E(\bar{u}), \Phi(\bar{u}))(\bar{M}) \rrbracket \\
= \llbracket \Gamma. \Box (E(\bar{M}), \Phi(\bar{M})) \rrbracket \\
= (id, \llbracket \Gamma. E(\bar{M}) \rrbracket)^* \llbracket \Gamma, e. \Box (e, \Phi(\bar{M})) \rrbracket \\
= (id, \llbracket \Gamma. E(\bar{M}) \rrbracket)^* \circ \forall (id \times \eta)(\llbracket \Gamma, x. \Phi(\bar{M}, x) \rrbracket)
\end{align*}
\]

induction

\[
\begin{align*}
\llbracket \Gamma. \Box (E(\bar{M}), \Phi(\bar{M})) \rrbracket \\
= \llbracket \Gamma. E(\bar{M}) \rrbracket^* \circ (\llbracket \Gamma. M \rrbracket \times id)^* (\llbracket \Gamma', x. \Phi(\bar{x})(x) \rrbracket) \\
= \llbracket \Gamma. E(\bar{M}) \rrbracket^* \circ (\llbracket \Gamma. \bar{M} \rrbracket \times id)^* (\llbracket \Gamma', e. \Box (e', \Phi(\bar{x})) \rrbracket) \\
= (\llbracket \Gamma. \bar{M} \rrbracket \times id) \circ (id, \llbracket \Gamma'. E(\bar{x}) \rrbracket) ((\llbracket \Gamma. \bar{M} \rrbracket))^* (\llbracket \Gamma', e. \Box (e', \Phi(\bar{x})) \rrbracket) \\
= (\llbracket \Gamma. \bar{M} \rrbracket) (\llbracket \Gamma'. E(\bar{x}) \rrbracket) (\llbracket \Gamma. \bar{M} \rrbracket)^* (\llbracket \Gamma', e. \Box (e', \Phi(\bar{x})) \rrbracket) \\
= (id, \llbracket \Gamma'. E(\bar{x}) \rrbracket) \circ (\llbracket \Gamma. \bar{M} \rrbracket)^* (\llbracket \Gamma', e. \Box (e', \Phi(\bar{x})) \rrbracket) \\
= (\llbracket \Gamma. \bar{M} \rrbracket)^* (id, \llbracket \Gamma'. E(\bar{x}) \rrbracket)^* (\llbracket \Gamma', e. \Box (e', \Phi(\bar{x})) \rrbracket).
\end{align*}
\]

The Soundness Theorem

The categorical semantics of the FIX logic is sound; indeed we have:
Proposition 5.2.2 ["Soundness for FIX Theories"] Let $C$ be a FIX hyperdoctrine, $Th$ a FIX theory and $M$ a model of $Th$ in $C$. Then $M$ satisfies any sequent in context which is a theorem of $Th$.

Proof We need to check that the collection of sequents in context which are satisfied by $M$ is closed under the rules for generating sequents in context. We give just one example of this, by checking the soundness of Existential Modality Entailment. We have

\[ \bigwedge_{\Theta \in \Lambda} [\Gamma, x.\Theta(\text{Val}(x))] \land [\Gamma, x.\Phi(x)] \leq [\Gamma, x.\Psi(\text{Val}(x))] \]

iff

\[ \bigwedge_{\Theta \in \Lambda} (id \times \eta)^* [\Gamma, e.\Theta(e)] \land [\Gamma, x.\Phi(x)] \leq (id \times \eta)^* [\Gamma, e.\Psi(e)]. \]

Pullback functions preserve meet, so this is iff

\[ (id \times \eta)^* [\Gamma, e.\Lambda(e)] \land [\Gamma, x.\Phi(x)] \leq (id \times \eta)^* [\Gamma, e.\Psi(e)]. \]

Using adjointness, this holds iff

\[ \exists (id \times \eta)((id \times \eta)^* [\Gamma, e.\Lambda(e)] \land [\Gamma, x.\Phi(x)]) \leq [\Gamma, e.\Psi(e)] \]

and from Frobenius Reciprocity iff

\[ [\Gamma, e.\Lambda(e)] \land \exists (id \times \eta)[\Gamma, x.\Phi(x)] \leq [\Gamma, e.\Psi(e)] \]

iff

\[ [\Gamma, e.\Lambda(e)] \land [\Gamma, e.\Diamond(e, \Phi)] \leq [\Gamma, e.\Psi(e)] \]

which is what we want. \qed

5.3 The Categorical Logic Correspondence

Proposition 5.3.1 For each FIX theory $Th$ over some FIX signature $Sg$, we may construct a syntactic FIX hyperdoctrine, which we shall denote by $C(Th)$ or sometimes $F$.

Proof The objects of the base FIX category are the types of $Sg$. The morphisms are equivalence classes of terms in a single variable context. We set

\[ F(\alpha, \beta) \overset{\text{def}}{=} \{ M(x) \mid x : \alpha \vdash M(x) : \beta \}/ = \]

where $M(x) = M'(y)$ iff $x : \alpha \vdash M(x) =_\beta M'(x)$ is a theorem of $Th$. We now define an $F$ indexed poset. For each object $\alpha \in F$ the underlying set of the partial order $F(\alpha)$ consists of equivalence classes of propositions in a single variable context, $x : \alpha \vdash \Phi(x)$ prop. We shall often omit the context itself; with this convention we impose a preorder by asking that

\[ \Phi(x) \leq \Psi(y) \quad \text{iff} \quad \Phi(x) \vdash \Psi(x). \]

82
The required partial order is the poset reflection of the preorder. Given a morphism \( F: \alpha \to \beta \) in \( \mathcal{F} \), the pullback function \( F^*: \mathcal{F}(\beta) \to \mathcal{F}(\alpha) \) is defined by substitution: \( F^*(\Phi(y)) \overset{\text{def}}{=} \Phi(F) \). We check that the conditions defining a FIX hyperdoctrine are satisfied. For condition (1), it is obvious that the fibres are meet semi lattices and that the pullback functions preserve the structure. For condition (2), the right adjoint to \( \text{Fst}(z)^*: \mathcal{F}(\gamma) \to \mathcal{F}(\gamma \times \alpha) \), will be written \( \forall^\pi: \mathcal{F}(\gamma \times \alpha) \to \mathcal{F}(\gamma) \) where

\[
\forall^\pi(\Phi(z)) \overset{\text{def}}{=} \forall_\alpha(x. \Phi((y, x))).
\]

That this is the required adjoint is well known; RBC is simple to check. We check condition (3) with some care. The right adjoint to

\[
(\text{Fst}(u), \text{Val}(\text{Snd}(u)))^*: \mathcal{F}(\gamma \times T\alpha) \to \mathcal{F}(\gamma \times \alpha)
\]

will be written \( \Box: \mathcal{F}(\gamma \times \alpha) \to \mathcal{F}(\gamma \times T\alpha) \) where

\[
\Box(\Phi(u)) \overset{\text{def}}{=} \Box(\text{Snd}(z), x. \Phi((\text{Fst}(z), x))).
\]

We check that this definition gives a right adjoint, that is

\[
\Phi(z) \vdash \Box(\Psi(u))
\]

\[
(\text{Fst}(u), \text{Val}(\text{Snd}(u)))^*(\Phi(z)) \vdash \Psi(u)
\]

We have

\[
u, \Phi((\text{Fst}(u), \text{Val}(\text{Snd}(u)))) \vdash \Psi(u)\]

\[
x, y, \Phi((y, \text{Val}(x))) \vdash \Psi((y, x))\quad\text{(sub)}
\]

\[
e, y, \Phi((y, e)) \vdash \Box(e, x. \Psi((y, x)))\quad\text{(\Box i)}
\]

\[
z, \Phi((\text{Fst}(z), \text{Snd}(z))) \vdash \Box(\text{Snd}(z), x. \Psi((\text{Fst}(z), x)))
\]

The converse direction is equally easy; we omit the remaining details for condition (3). For condition (4) we define an operation

\[+(\gamma \times \alpha) \times \mathcal{F}(\gamma \times \alpha') \to \mathcal{F}(\gamma \times (\alpha + \alpha')).\]

For elements \( \Phi(v) \in \mathcal{F}(\gamma \times \alpha) \) and \( \Psi(w) \in \mathcal{F}(\gamma \times \alpha') \) we set

\[\Phi(v) + \Psi(w) \overset{\text{def}}{=} (\Phi + \Psi)(P(u)) ,\]

where \( P(u) \) is the isomorphism \( P(u): \gamma \times (\alpha + \alpha') \to (\gamma \times \alpha) + (\gamma \times \alpha') \). To see that this satisfies condition (4), take morphisms \( M(\nu): \gamma \times \alpha \to \delta \) and \( N(\nu): \gamma \times \alpha' \to \delta \) together with elements \( \Theta(z) \in \mathcal{F}(\gamma \times \delta) \) and \( \Pi(u) \in \mathcal{F}(\gamma \times (\alpha + \alpha')) \). Then it remains to show that

\[
\left\{\begin{array}{l}
(\text{Fst}(\nu), \text{Inl}(\text{Snd}(\nu)))^*\Pi(u) \& \Phi(v) \vdash (\text{Fst}(\nu), M(\nu))^*\Theta(z) \\
(\text{Fst}(\nu), \text{Inl}(\text{Snd}(\nu)))^*\Pi(u) \& \Psi(w) \vdash (\text{Fst}(\nu), N(\nu))^*\Theta(z)
\end{array}\right.
\]

\[
\Pi(u) \& (\Phi + \Psi)(P(u)) \vdash (\text{Fst}(\nu), \{M, N\}(P(u)))^*\Theta(z)
\]

83
which follows from careful application of the rule (+ad) and the Coproduct Equations rules. Conditions (5) and (6) are easy to verify. Moving on to condition (7), the left adjoint to \((id \times \Delta)^* : F(\gamma \times \alpha \times \alpha) \rightarrow F(\gamma \times \alpha)\), is defined by

\[
\exists (id \times \Delta)(\Phi(u)) \overset{\text{def}}{=} \Phi((\text{Fst}(z), (\text{Fst}(\text{Snd}(z)), \text{Snd}(\text{Snd}(z)))) \& \text{Fst}(\text{Snd}(z)) = \text{Snd}(\text{Snd}(z)).
\]

We have now given all the structure needed to specify \(F\); the remaining details are routine and omitted. Note that condition (10) is immediate from the construction of \(F\). \(\square\)

**Proposition 5.3.2** Given a FIX hyperdoctrine \(C\), then we can define a FIX theory which we denote by \(Th(C)\).

**Proof** The basic ground types and basic function symbols for the base FIX category are exactly those defined in Section 2.5. For each object \(A_1 \times \ldots \times A_n\) in \(C\) there are relation symbols \(R : A_1, \ldots, A_n\) which are copies of the elements in the fibre \(C(A_1 \times \ldots \times A_n)\). This gives us data for a FIX signature; there is an obvious canonical structure for this signature in \(C\) which we denote by \(G\). Then the axioms of the theory \(Th(C)\) are exactly those sequents in context which are satisfied by the canonical structure; the theorems of \(Th(C)\) are generated by the usual rules of the FIX logic. \(\square\)

Now we can state the categorical logic correspondence:

**Theorem 5.3.3** Let \(C\) be a FIX hyperdoctrine; then there is an equivalence of hyperdoctrines (i.e. an equivalence of indexed posets)

\[
Eq : C(Th(C)) \simeq C : Eq^{-1},
\]

where \(Eq\) is a FIX hyperdoctrine morphism. Thus there is a categorical equivalence of base categories, together with an isomorphism of posets

\[
Eq_{\alpha} : C(Th(C))(\alpha) \rightarrow C(Eq(\alpha)) : (Eq^{-1})_{Eq(\alpha)}.
\]

**Proof** For the definition of \(Eq\) and \(Eq^{-1}\) see Theorem 3.4.3. Define \(Eq_{\alpha}(\Phi(x)) \overset{\text{def}}{=} [x.\Phi(x)]_G\) and \((Eq^{-1})_{\alpha}(R) \overset{\text{def}}{=} R(x)\) where \(R \in C([\alpha]_G)\). We omit the routine details of the proof. \(\square\)

## 5.4 The Logical Relations Hyperdoctrine

Now that we have formalised the correspondence between FIX theories and FIX hyperdoctrines, we define a new FIX hyperdoctrine and use it, together with its corresponding theory/logic, to prove Theorems 4.5.4, 4.5.5 and 4.5.6. We shall write \(F\) for the FIX hyperdoctrine constructed from the pure FIX logic.
Definition 5.4.1 Let $\Gamma: \mathcal{F} \to \omega\text{Cpo}$ denote the functor which assigns to each object $\alpha \in \mathcal{F}$ its set $\Gamma(\alpha)$ of global elements equipped with the discrete partial order. We construct a new FIX hyperdoctrine, denoted by $\mathcal{L}r$, using a construction that is closely allied to the theory of logical relations. An object of $\mathcal{L}r$ is a triple $(D, \triangleleft, \alpha)$, where $D \in \omega\text{Cpo}$, $\alpha \in \mathcal{F}$ and $\triangleleft$ is an inclusive subset of $D \times \Gamma(\alpha)$. A morphism $(D, \triangleleft, \alpha) \to (D', \triangleleft', \alpha')$ in $\mathcal{L}r$ is a pair $(f, F)$, where $f: D \to D'$ in $\omega\text{Cpo}$ and $F: \alpha \to \alpha'$ in $\mathcal{F}$, satisfying the following condition:

$$\forall d \in D. M \in \Gamma(\alpha). d \triangleleft M \supset f(d) \triangleleft' FM.$$ 

It remains to define a $\mathcal{L}r$ indexed poset. We shall denote the fibre at an object $(D, \triangleleft, \alpha)$ by $\mathcal{L}r(D, \triangleleft, \alpha)$. The elements of the fibre consist of all triples $(S, \trianglelefteq, \Phi(x))$, where

1. $S \in I(D)$, i.e. $S$ runs over the inclusive subsets of the $\omega\text{Cpo} D$.
2. $\Phi(x) \in \mathcal{F}(\alpha)$.
3. $\trianglelefteq \in I([S \times \Gamma(\alpha)] \cap \triangleleft)$ where $\Gamma(\alpha) \triangleq \{ M \in \Gamma(\alpha) \mid \vdash \Phi(M) \}$; note that $[S \times \Gamma(\alpha)] \cap \triangleleft$ is an $\omega\text{Cpo}$.

The order is given by inclusion in the first and second coordinates, and by entailment in the third. Given a morphism $(f, F): (D', \triangleleft', \alpha') \to (D, \triangleleft, \alpha)$ in $\mathcal{L}r$, we define the pullback function $(f, F)^*: \mathcal{L}r(D, \triangleleft, \alpha) \to \mathcal{L}r(D', \triangleleft', \alpha')$ by

$$(f, F)^*(S, \trianglelefteq, \Phi(x)) \triangleq (f^{-1}(S), \trianglelefteq^*, \Phi(F))$$

where $\trianglelefteq^* \triangleq \{(d, M) \in [f^{-1}(S) \times \Gamma(\alpha')] \cap \triangleleft | f(d) \leq FM \}$.

This completes the definition of the logical relations hyperdoctrine, $\mathcal{L}r$. Clearly we need to see that $\mathcal{L}r$ really is a FIX hyperdoctrine:

Proposition 5.4.2 The construction of $\mathcal{L}r$ detailed in Definition 5.4.1 gives rise to a FIX hyperdoctrine.

Proof It is a simple exercise to verify that this definition makes sense. We check that each $(f, F)^*$ is indeed monotone. Suppose that $(S_1, \trianglelefteq_1, \Phi_1(x)) \leq (S_2, \trianglelefteq_2, \Phi_2(x))$ in the fibre $\mathcal{L}r(D, \triangleleft, \alpha)$. Then,

- $S_1 \subset S_2$ and so $f^{-1}(S_1) \subset f^{-1}(S_2)$.
- $\Phi_1(x) \vdash \Phi_2(x)$ and so $\Phi_1(F) \vdash \Phi_2(F)$ by substitution.
- To see that $\trianglelefteq_1 \subset \trianglelefteq_2$ note that $\Phi_1(FM) \vdash \Phi_2(FM)$. 

85
We also need to see that given

$$(D'', <'', \alpha'') \xrightarrow{(f', F')} (D', <', \alpha') \xrightarrow{(f, F)} (D, <, \alpha)$$

it is the case that $(f', F')^* \circ (f, F)^* = (ff', FF')^*$. The details are tedious but easy and so they are omitted. Now we have to check that the definitions of objects and morphisms yield a base FIX category, and that the $Lr$ indexed poset does indeed constitute a FIX hyperdoctrine. Firstly we check that we have a FIX category; most of the details are simple calculations, once it is clear how one defines the various categorical constructs.

The terminal object is $(1, \ulcorner \text{unit}, \text{unit} \urcorner)$ where $\ulcorner \text{unit} \urcorner \text{id}_{\text{unit}}$. The binary product is given by

$$(D, <, \alpha) \times (D', <', \alpha') \overset{\text{def}}{=} (D \times D', < \times <', \alpha \times \alpha'),$$

where (putting $<_\times \overset{\text{def}}{=} < \times <'$),

$$(d, d') <_\times N \iff d < \text{Fst}(N) \text{ and } d' <' \text{Snd}(N).$$

It is clear that $<_\times$ is inclusive, and easy to check the remaining details. Exponentials of objects are defined by

$$(D', <', \alpha'), \rightarrow (D, <, \alpha) \overset{\text{def}}{=} (D' \rightarrow D, <' \rightarrow <, \alpha' \rightarrow \alpha),$$

where

$$f < < \rightarrow < F \iff \forall d' \in D'. \forall L' \in \Gamma(\alpha'), d' <' L' \supset f(d') < \text{ap} \circ (F, L')$$

and $\text{ap}$ is the evaluation morphism in $\mathcal{F}$. The transpose rule is given by

$$\frac{(f', F') \colon (D \times D', <_\times, \alpha \times \alpha') \rightarrow (D'', <'', \alpha'')}{(\text{cur}(f), \text{cur}(F)) \colon (D, <, \alpha) \rightarrow (D' \rightarrow D'', <' \rightarrow <'', \alpha' \rightarrow \alpha'')}$$

and the evaluation morphism is $(\text{ap}, \text{ap})$. Finite coproducts are also defined in the same (hopefully now familiar) coordinatewise/logical relations manner. The NNO of $Lr$ is specified by $(N, <_{\text{nat}}, \text{nat})$, where $n <_{\text{nat}} N \iff N = \text{Suc}^n(O)$,\textsuperscript{1} and the zero and successor morphisms are the expected coordinatewise ones. We now show that for a particular choice of monad, the category $Lr$ does indeed become a lef category. The action of the monad on objects is specified by $T(D, <, \alpha) \overset{\text{def}}{=} (D_\bot, <_T, T\alpha)$, where

$$e <_T E \iff \forall d \in D, [d] = e \supset \exists M \in \Gamma(\alpha), d < M \& \eta_\alpha M = E,$$

and $\eta(D, <, \alpha) \overset{\text{def}}{=} (\iota, \eta_\alpha) : (D, <, \alpha) \rightarrow (D_\bot, <, T\alpha)$, with $\iota : D \rightarrow D_\bot$ the canonical inclusion. Finally the lifting rule is

$$\frac{(f, F') \colon (D \times D', <_\times, \alpha \times \alpha') \rightarrow (D'', <'', T\alpha'')}{(f_\bot, \text{lift}(F')) \colon (D \times D'_\bot, < \times <'', \alpha \times T\alpha') \rightarrow (D''_\bot, <'', T\alpha'')}$$

\textsuperscript{1}We shall often drop the sequent symbol $\vdash$ from equalities such as $\vdash N = \text{Suc}^n(O)$
where of course \( f^\perp(d, [d']) = f(d, d') \) and \( f^\perp(d, \perp) = \perp \).

Now we show that \( \mathcal{L}r \) does indeed possess a FPO. This will be determined up to isomorphism; thus as for the previous constructs we exhibit a candidate and show that it satisfies the required properties. The expected candidate for the FPO would be \((\Omega, \triangleleft_{\text{fix}}, \text{fix})\), with structure morphism \((\sigma, \sigma)\). By definition of the action of the monad on objects, in the relation \( \triangleleft_{T}^{\text{fix}} \) one has \( \perp \triangleleft_{T}^{\text{fix}} M \), for any \( M \in \Gamma(T\text{fix}) \). As \((\sigma, \sigma)\) must preserve the relation, then \( 0 \triangleleft_{\text{fix}} \sigma M \) must hold, and the action of the monad yields \( [0] \triangleleft_{T}^{\text{fix}} \eta \sigma M \). Once again \((\sigma, \sigma)\) preserves this, so we must have \( 1 \triangleleft_{\text{fix}} \sigma \eta \sigma M \). In general we are forced to have \( n \triangleleft_{\text{fix}} (\sigma \eta)^n \sigma M \). Finally, considering that the relation \( \triangleleft_{\text{fix}} \) is to be a certain inclusive subset, we are led to the following definition:

\((\Omega, \triangleleft_{\text{fix}}, \text{fix})\) is a FPO for \( T \) over \( \mathcal{L}r \), where

- \( n \triangleleft_{\text{fix}} N \iff \exists M \in \Gamma(\text{fix}).N = (\sigma \eta)^n M \), and
- \( T \triangleleft_{\text{fix}} N \iff \forall n \in \Omega \setminus \{T\}.n \triangleleft_{\text{fix}} N \).

We check that the relation \( \triangleleft_{\text{fix}} \) is inclusive. Take a chain in \( \triangleleft_{\text{fix}} \), say \( \{n_r \mid r \in \mathbb{N}\} \) where \( N \in \Gamma(\text{fix}) \). We need to check that \( \forall \{n_r \mid r \in \mathbb{N}\} \triangleleft_{\text{fix}} N \). If \( \forall \{n_r \mid r \in \mathbb{N}\} \) is not \( T \) we are done. Otherwise, given any \( n \in \Omega \setminus \{T\} \), we can choose \( r \in \mathbb{N} \) such that \( n_r \geq n \). As \( n_r \triangleleft_{\text{fix}} N \), we get

\[ N = (\sigma \eta)^{n_r} M = (\sigma \eta)^n (\sigma \eta)^{n_r-n} M, \]

and so \( n \triangleleft_{\text{fix}} N \). As \( n \) was arbitrary, we are done. Now we check that \((\sigma, \sigma)\) is a morphism in \( \mathcal{L}r \), where \((\sigma, \sigma) \colon (\Omega, \triangleleft_{\text{fix}}, T\text{fix}) \to (\Omega, \triangleleft_{\text{fix}}, \text{fix}) \). We have three cases to cover.

1. If \( \perp \triangleleft_{T}^{\text{fix}} E \) then \( \sigma(\perp) = 0 \triangleleft_{\text{fix}} \sigma E \).

2. If \([n] \triangleleft_{T}^{\text{fix}} E \) note that \( E = \eta(\sigma \eta)^n M \) for some \( M \).

3. Suppose that \([T] \triangleleft_{T}^{\text{fix}} E \). Then \( T \triangleleft_{\text{fix}} N \) and hence \( \forall n \in \Omega \setminus \{T\}.n \triangleleft_{\text{fix}} N \). In particular, we have \( n-1 \triangleleft_{\text{fix}} N \), and so there is some \( M \in \Gamma(\text{fix}) \) for which \( N = (\sigma \eta)^{n-1} M \), giving \( \sigma \eta N = (\sigma \eta)^n M \). So we have \( \forall n \in \Omega \setminus \{T\}.n \triangleleft_{\text{fix}} \sigma \eta N \), that is \( \perp \triangleleft_{\text{fix}} \sigma E \).

Finally, we have to verify that our definition yields an initial \( T \) algebra in \( \mathcal{L}r \). Take \((f, F) \colon (D \perp, \triangleleft_T, T \alpha) \to (D, \triangleleft, \alpha) \). The unique mediating morphism for \((\sigma, \sigma)\) has to be \((\tilde{f}, \tilde{F}) \defeq (it(f), it(F)) \) whose coordinates are the mediating morphisms in \( \omega \mathcal{C}po \) and \( \mathcal{F} \). Firstly we check that it is a morphism in \( \mathcal{L}r \). Suppose that \( n \triangleleft_{\text{fix}} N \). Then for some \( M \) we get \( N = (\sigma \eta)^{n} M \). From the definition of the \( \triangleleft_T \) relation, we get \( \perp \triangleleft_T let(\eta \tilde{F}) \sigma^{-1} M \) and so \( f(\perp) \triangleleft Flet(\eta \tilde{F}) \sigma^{-1} M = \tilde{F} M \). Now suppose that \( f^r(\perp) \triangleleft \tilde{F} (\sigma \eta)^{-1} M \), where \( r \leq n - 1 \). Clearly \([f^r(\perp)] \triangleleft_T \eta \tilde{F} (\sigma \eta)^{-1} M \), and so \( f^{r+1}(\perp) \triangleleft \tilde{F} (\sigma \eta)^{r+1} M \). Inductively we have \( f^{n+1}(\perp) \triangleleft F(\sigma \eta)^n M = FN \), which is
what we had to prove. Finally, if \( T \triangleleft_{\text{fix}} N \) we need \( \forall f^n(\bot) \triangleleft \tilde{F} N \), which follows from inclusivity of \( \triangleleft \). We omit to verify that the morphisms
\[
([T], \omega) : (1, \triangleleft_{\text{unit}}, \text{unit}) \to (\Omega, \triangleleft_{\text{fix}}, T \text{fix}) \quad (\sigma, \sigma) : (\Omega, \triangleleft_{\text{fix}}, T \text{fix}) \to (\Omega, \triangleleft_{\text{fix}}, \text{fix})
\]
constitute a FPO in \( \mathcal{L}r \).

We now verify conditions (1) to (10) of Definition 5.1.1. It is easy to see that condition (1) holds. We check condition (2) in detail. Firstly we define the right adjoint to
\[
(\pi, \text{Fst}(z))^* : \mathcal{L}r(C, \triangleleft', \gamma) \to \mathcal{L}r(C \times D, \triangleleft' \times \triangleleft, \gamma \times \alpha)
\]
which we denote by
\[
\forall : \mathcal{L}r(C \times D, \triangleleft_x, \gamma \times \alpha) \to \mathcal{L}r(C, \triangleleft', \gamma)
\]
where we set \( \forall \pi(S, \triangleleft_x, \Phi(z)) \equiv (\forall \pi(S), \triangleleft^0_x, \forall \pi(\Phi(z))) \) with
\[
\triangleleft^0_x \equiv \{(c, N) \in \{(V \pi(S) \times \Gamma_{\forall \pi(\Phi(z))}(\gamma))\cap \triangleleft'\} \land \forall d \in D. \forall M \in \Gamma(\alpha). d \triangleleft M \supset (c, d) \triangleleft_x (M, N)\}.
\]
This makes sense. For certainly \( \forall \pi(S) \in \mathcal{I}(C) \) and \( \forall \pi(\Phi(z)) \in \mathcal{F}(\gamma) \). Let us see that \( \triangleleft^0_x \in \mathcal{I}(\{V \pi(S) \times \Gamma_{\forall \pi(\Phi(z))}(\gamma)\} \cap \triangleleft') \). With the obvious notation, let \( \{(c_i, N) \mid i \in \mathbb{N}\} \) be a chain in \( \triangleleft^0_x \) and so \( \forall d \in D. \forall M \in \Gamma(\alpha). d \triangleleft M \) we have \( \{(c_i, d), (N, M)\} \mid i \in \mathbb{N}\} \) in \( \triangleleft_x \). But \( \triangleleft_x \) is inclusive, so the supremum of the latter chain lies in \( \triangleleft_x \); for all \( d \) and \( M \) such that \( d \triangleleft M \). But this is exactly that \( (\forall \{c_i \mid i \in \mathbb{N}\}, N) \in \triangleleft^0_x \). Finally, it is clear that \( \forall \pi \) is monotone. Now we verify that \( (\pi, \text{Fst}(z))^* \triangleleft \forall \pi \). Take \( (U, \triangleleft', \Psi(y)) \in \mathcal{L}r(C, \triangleleft', \gamma) \) and \( (S, \triangleleft_x, \Phi(z)) \in \mathcal{L}r(C \times D, \triangleleft_x, \gamma \times \alpha) \). Then we need to check that
\[
\frac{(\pi^{-1}(U), \triangleleft^*_x, \Psi(\text{Fst}(z))) \leq (S, \triangleleft_x, \Phi(z))}{(U, \triangleleft', \Psi(y)) \leq (\forall \pi(S), \triangleleft^0_x, \forall \pi(\Phi(z)))}
\]
It is clear that all is well in the first and third coordinates, as both \( \omega \mathcal{C}po \) and \( \mathcal{F} \) are \( \text{FIX} \) hyperdoctrines. All we need to do is examine the second coordinates.
Suppose that \( \triangleleft^*_x \subseteq \triangleleft_x \). Hence it remains to show \( \triangleleft' \subseteq \triangleleft^0_x \). Let \( c \triangleleft' N \). Thus we need
1. \( c \in \forall \pi(S) \),
2. \( N \in \Gamma_{\forall \pi(\Phi(y))}(\gamma) \),
3. \( c \triangleleft' N \),
4. \( \forall d \in D. \forall M \in \Gamma(\alpha). d \triangleleft M \supset (c, d) \triangleleft_x (M, N) \).

We check each of these in turn.
1. Clearly \( c \in U \subseteq \forall \pi(S) \).
2. We are given \( \vdash \Psi(N) \) and \( \Psi(y) \vdash \forall_x(x. \Phi((y, x))) \), hence \( \vdash \forall_x(x. \Phi((N, x))) \).

3. Immediate.

4. By definition

\[
(\preceq)^* = \{((c, d), (N, M)) \in [\pi^{-1}(U) \times \Gamma_{\Psi(Fst(z))}(\gamma \times \alpha)] \cap \prec | c \preceq \ N \}.
\]

Suppose that \( d \preceq M \). We have \( c \in U \), so \( (c, d) \in \pi^{-1}(U) \) and \( \vdash \Psi(N) \) implying \( (N, M) \in \Gamma_{\Psi(Fst(z))}(\gamma \times \alpha) \). Also \( c \prec \ N \) and so \( (c, d) \prec (N, M) \). With these facts, we see that \( (c, d)(\preceq)^*(N, M) \) and using the hypothesis we are done.

Now suppose that \( \preceq \in \preceq^\circ \); it remains to show \( (\preceq)^* \in \preceq^\circ \). Let \( (c, d)(\preceq)^*(N, M) \). Then from the supposition we get \( c \preceq \ N \), which means that \( (c, d) \preceq (N, M) \). So we do get the required right adjoint.

We must verify that RBC holds, namely that the square

\[
\begin{array}{ccc}
\mathcal{L}r(C \times D, \preceq' \times \preceq, \gamma \times \alpha) & \xrightarrow{\forall \pi} & \mathcal{L}r(C, \preceq', \gamma) \\
(f \times id, F \times id)^* & \downarrow & (f, F)^* \\
\mathcal{L}r(C' \times D, \preceq'' \times \preceq, \gamma' \times \alpha) & \xrightarrow{\forall \pi} & \mathcal{L}r(C', \preceq'', \gamma')
\end{array}
\]

Of course, we already know that everything is fine in the first and third coordinates. We just need to check the second coordinate. We have that

\[
\preceq^\circ_x = \{(c, N) \in [\forall \pi(S) \times \Gamma_{\Psi_{\Phi(z)}}(\gamma)] \cap \prec | \forall d. \forall M. d \preceq M \supset (c, d) \preceq_x (N, M) \}
\]

\[
\preceq_x = \{((c', d), (N', M)) \in [(f \times id)^{-1}(S) \times \Gamma_{\Phi(z)}(\gamma \times \alpha)] \cap \prec'' \times \prec | (f \times id)(c', d) \preceq_x (F \times id)(N', M) \}
\]

\[
(\preceq^\circ_x)^* = \{((c', N') \in [f^{-1} \circ \forall \pi(S) \times \Gamma_{\Phi(z)}(\gamma)] \cap \prec'' | f(c') \preceq^\circ_x FN' \}
\]

\[
(\preceq_x^*)^0 = \{((c', N') \in [\forall \pi \circ (f \times id)^{-1}(S) \times \Gamma_{\Psi_{\Phi(z)}}(\gamma)] \cap \prec'' | \forall d. \forall M. d \preceq M \supset (c', d) \preceq_x^* \langle N', M \rangle \}
\]

Suppose that \( c' (\preceq_x^*)^0 N' \). We show \( c' (\preceq_x^*)^0 N' \). Hence we need to see that \( d \preceq M \) implies \( (c', d) \preceq_x^* \langle N', M \rangle \). This amounts to showing

1. \( (c', d) \in (f \times id)^{-1}(S) \).
2. \( \langle N', M \rangle \in \Gamma_{\Phi(Fst(z'))}(\gamma' \times \alpha) \).
3. \( (c', d) \prec'' \times \prec (N', M) \).
4. \( (f(c'), d) \preceq_x \langle FN', M \rangle \).
We check each of these:

1. Note that \( c' \in f^{-1} \circ \forall \pi (S) = \forall \pi \circ (f \times id)^{-1} (S) \).

2. We have \( N' \in \Gamma_{\forall \alpha (x, \Phi (F, x))} \) and hence \( \vdash \Phi ((FN', M)) \).

3. Immediate from \( c' \triangleleft_{\alpha} N' \).

4. Immediate from \( f(c') \triangleleft_{\alpha} FN' \).

Thus \( \langle \leq_{\alpha} \rangle_{\alpha} \subset \langle \leq_{\alpha} \rangle_{\alpha} \); the reverse inclusion is similar.

We move on to condition (3). The right adjoint to \((id \times \iota, id \times \eta)^*: \mathcal{L}r(C \times D, \triangleleft_{\alpha} <_{T}, \gamma \times T \alpha) \rightarrow \mathcal{L}r(C \times D, \triangleleft_{\alpha} <, \gamma \times \alpha)\) which we shall write as
\[ \Box: \mathcal{L}r(C \times D, \triangleleft_{\alpha}, \gamma \times \alpha) \rightarrow \mathcal{L}r(C \times D, \triangleleft_{\alpha}^{T}, \gamma \times T \alpha) \]
is defined by \( \Box (S, \triangleleft_{\alpha}, \Phi (u)) \triangleq (\Box (S), \triangleleft_{\alpha}^{T}, \Box (\Phi (u))) \) where \( \Box (S) \) and \( \Box (\Phi (u)) \) have the expected meaning, and where
\[ \triangleleft_{\alpha}^{T} \triangleq \{(c, e), (N, E') \in [\Box (S) \times \Gamma_{\Box (\Phi (u))} (\gamma \times T \alpha)] \cap \triangleleft_{\alpha}^{T} \} \]
\[ \forall d, \forall M, d \triangleleft M \land e = [d \land E = \text{Val}(M) \supset (c, d) \triangleleft_{\alpha} (N, M)] \).

We omit to check that the definition of \( \Box \) makes sense, and that it is the required adjoint. We shall just check that \( \text{RBC} \) does indeed hold, i.e. the following square commutes:
\[ \begin{array}{ccc}
\mathcal{L}r(C \times D, \triangleleft_{\alpha}, \gamma \times \alpha) & \xrightarrow{\Box} & \mathcal{L}r(C \times D, \triangleleft_{\alpha}^{T}, \gamma \times T \alpha) \\
((f \times id), (F \times id))^* & & ((f \times id), (F \times id))^* \\
\mathcal{L}r(C' \times D, \triangleleft_{\alpha}^{\prime} <, \gamma' \times \alpha) & \xrightarrow{\Box} & \mathcal{L}r(C' \times D, \triangleleft_{\alpha}^{\prime} <_{T}, \gamma' \times T \alpha) \\
\end{array} \]

Once again, all we need to do is check things work in the second coordinate. We have:
\[ \leq_{\alpha} = \{(c, e), (N, E) \in [\Box (S) \times \Gamma_{\Box (\Phi (u))} (\gamma \times T \alpha)] \cap \triangleleft_{\alpha}^{T} \} \]
\[ \forall d, \forall M, d \triangleleft M \land e = [d \land E = \text{Val}(M) \supset (c, d) \triangleleft_{\alpha} (N, M)] \}
\[ \leq_{\alpha}^{*} = \{(c', d), (N', M) \in [(f \times id)^{-1} (S) \times \Gamma_{(F \times id)^* (\Phi (u))} (\gamma' \times \alpha)] \cap \triangleleft_{\alpha}^{T} \} \]
\[ (\leq_{\alpha}^{*})^{*} = \{(c', e), (N', E) \in [(f \times id)^{-1} \circ \Box (S) \times \Gamma_{(F \times id)^* (\Phi (u))} (\gamma' \times T \alpha)] \] \[ \land \triangleleft_{\alpha}^{T} \land \Box (c', e) \triangleleft_{\alpha}^{*} (FN', E) \}
\[ (\leq_{\alpha})^{*} = \{(c', e), (N', E) \in [\Box \circ (f \times id)^{-1} (S) \times \Gamma_{\Box (F \times id)^* (\Phi (u))} (\gamma' \times T \alpha)] \] \[ \land \triangleleft_{\alpha}^{T} \land \Box (c', d) \triangleleft_{\alpha}^{*} (N', M) \}

90
Suppose that \((c', e)(\preceq^*_{\mathcal{X}})^*(N', E)\). Then it remains to prove \((c', e)(\preceq^*_{\mathcal{X}})^*(N', E)\). This means given any \(d \in D\) and \(M \in \Gamma(\alpha)\) for which \(d \triangleleft M\), \(e = [d]\) and \(E = \text{Val}(M)\) we must show

1. \((c', d) \in (f \times id)^{-1}(S)\).
2. \(\langle N', M \rangle \in \Gamma_{(f \times id)^{-1}((\Phi(\alpha)))}((\gamma') \times \alpha)\).
3. \((c', d) \preceq^* \triangleleft (N', M)\).
4. \((f(c'), d) \preceq^* (FN', M)\).

Using the hypothesis, we have \((f(c'), e) \preceq^* (FN', E)\) and hence

\[d \triangleleft M \& e = [d] \& E = \text{Val}(M) \supset (f(c'), d) \preceq^* (FN', M)\].

We check each of 1 to 4:

1. \((c', [d]) \in (f \times id)^{-1} \circ \Box(S) = \Box \circ (f \times id)^{-1}(S)\) and so \((c', d) \in (f \times id)^{-1}(S)\).
2. \(\langle N', E \rangle \in \Gamma_{(\Box(\text{Snd}(z), x. \Phi((\text{FFst}(z), x)))}((\gamma') \times T\alpha)\), which means that
   \[\vdash \Box(E, x. \Phi((FN', z))).\]
   But \(E = \text{Val}(M)\), thus appealing to Proposition 4.5.1 we have \(\vdash \Phi((FN', M))\).
3. By hypothesis.
4. Immediate.

Suppose that \((c', e)(\preceq^*_{\mathcal{X}})^*(N', E)\). It remains to prove \((c', e)(\preceq^*_{\mathcal{X}})^*(N', E)\). Thus given \(d \in D\) and \(M \in \Gamma(\alpha)\) for which \(e = [d]\), \(E = \text{Val}(M)\) and \(d \triangleleft M\), we need to show

1. \((f(c'), e) \in \Box(S)\),
2. \(\langle FN', E \rangle \in \Gamma_{\Box(\Phi(\alpha))}((\gamma') \times T\alpha)\),
3. \((f(c'), e) \preceq^* (FN', E)\),
4. \((f(c'), d) \preceq^* (FN', M)\).

Using the hypothesis, we get

\[d \triangleleft M \& e = [d] \& E = \text{Val}(M) \supset (f(c'), d) \preceq^* (FN', M)\].

We check each of 1 to 4:

1. \((c', [d]) \in \Box \circ (f \times id)^{-1}(S) = (f \times id)^{-1} \circ \Box(S)\).
2. We have \(\langle N', E \rangle \in \Gamma_{\Box(\text{Snd}(z), x. \Phi((\text{FFst}(z), x)))}((\gamma') \times T\alpha)\), and so
   \[\vdash \Box(E, x. \Phi((FN', z))).\]
   But \(E = \text{Val}(M)\) and so \(\vdash \Phi((FN', M))\) by appeal to Proposition 4.5.1.

91
3. Trivial.

4. Immediate.

We now define the left adjoint to

\[(id \times \eta, id \times \eta)^* : \mathcal{L}(C \times D_{\perp}, \trianglelefteq' \times \trianglelefteq, \gamma \times T\alpha) \to \mathcal{L}(C \times D, \trianglelefteq' \times \trianglelefteq, \gamma \times \alpha)\]

Denote this by

\[\diamond : \mathcal{L}(C \times D, \trianglelefteq_x, \gamma \times \alpha) \to \mathcal{L}(C \times D_{\perp}, \trianglelefteq_x^T, \gamma \times T\alpha)\]

where we set \(\diamond(S, \trianglelefteq_x, \Phi(u)) \overset{\text{def}}{=} (\diamond(S), \trianglelefteq_x^\circ, \diamond(\Phi(u)))\) with

\[\trianglelefteq_x^\circ \overset{\text{def}}{=} \{((c, e), (N, E)) \in [\diamond(S) \times \Gamma_{\diamond(\Phi(u))}(\gamma \times T\alpha)] \cap \trianglelefteq_x^T|\exists d, \exists M, d \trianglelefteq M \& e = [d] \& E = \text{Val}(M) \& (c, d) \leq_x (N, M)\}\]

We omit to check that this is well defined and that LBC is satisfied, but give brief details of the Frobenius Reciprocity condition. Take

\[(U, \trianglelefteq_x^T, \Psi(z)) \in \mathcal{L}(C \times D_{\perp}, \trianglelefteq_x^T, \gamma \times T\alpha)\]

and

\[(S, \trianglelefteq_x, \Phi(u)) \in \mathcal{L}(C \times D, \trianglelefteq_x, \gamma \times \alpha)\]

Observe that \(U \cap \diamond(S) = \diamond(((id \times \epsilon)^{-1}(U) \cap S)\) and

\[\Psi((y, e)) \& \diamond(e, x, \Phi((y, x))) \vdash \diamond(e, x, \Psi((y, \text{Val}(x))) \& \Phi((y, x))).\]

We require \(((\trianglelefteq_x^T)^* \cap \trianglelefteq_x^\circ)^\circ = \trianglelefteq_x^T \cap \trianglelefteq_x^\circ\). Suppose that \((c, e)((\trianglelefteq_x^T)^* \cap \trianglelefteq_x^\circ) (N, E)\).

Then there exist \(d\) and \(M\) for which \((c, d)((\trianglelefteq_x^T)^* \cap \trianglelefteq_x^\circ) (N, M)\). Unravelling the supposition and appealing to the above observation, we conclude that \((c, e) \in U \cap \diamond(S)\) and \(\vdash \Psi((N, E')) \& \diamond(E, x, \Phi((N, x)))\). Using Proposition 4.5.1 we may deduce

\(\vdash \Psi((N, E)) \& \Phi((N, M))\). So we can conclude that \((c, e) \leq_x (N, E)\) and

\[(c, e) \leq_x (N, E).\]

Suppose that \((c, e)((\trianglelefteq_x^T \cap \trianglelefteq_x^\circ) (N, E)\). We need to find \(d\) and \(M\) for which \((c, d)((\trianglelefteq_x^T)^* (N, M)\) and \((c, d) \leq_x (N, M)\). Now \((c, e) \leq_x (N, E)\) implies that there are \(d\) and \(M\) for which \(d \trianglelefteq M, e = [d]\) and \(E = \text{Val}(M)\). From the observation above, we deduce that \((c, e) \in \diamond((id \times \epsilon)^{-1} \cap S)\) and \(\vdash \diamond(E, x, \Psi((N, \text{Val}(x))) \& \Phi((N, x)))\).

Thus \((c, d) \in (id \times \epsilon)^{-1}(U) \cap S\) and appealing to Proposition 4.5.1 we deduce

\(\vdash \Psi((N, E)) \& \Phi((N, M))\). Using these conclusions along with the supposition we are done.

Now for condition (4). We define the operation +

\[+: \mathcal{L}(C \times D, \trianglelefteq_c \times \trianglelefteq, \gamma \times \alpha) \times \mathcal{L}(C \times D', \trianglelefteq_{c'} \times \trianglelefteq', \gamma \times \alpha') \to \mathcal{L}(C \times (D + D'), \trianglelefteq_c \times (\trianglelefteq + \trianglelefteq'), \gamma \times (\alpha + \alpha'))\]

92
by sending the elements

\[(I, \preceq_1, \Phi(v)) \in Lr(C \times D, \preceq_C \times \preceq, \gamma \times \alpha)\]
\[(J, \preceq_2, \Psi(w)) \in Lr(C \times D', \preceq_C \times \preceq', \gamma \times \alpha')\]

to \((I + J, \preceq_3, \Phi(v) + \Psi(w))\) where

\[\preceq_3 \overset{\text{def}}{=} \{((c, e), (N, E)) \in [(I + J) \times \Gamma_{\Phi(v) + \Psi(w)}(\gamma \times (\alpha + \alpha'))] \cap \preceq_C \times (\preceq + \preceq') | \exists d. \exists M. d \preceq M \& e = i(d) \& E = \lnl(M) \& (c, d) \preceq_1 \langle N, M \rangle \}
\]

or

\[\exists d'. \exists M'. d' \preceq' M' \& e = j(d') \& E = \lntl(M') \& (c, d') \preceq_2 \langle N, M' \rangle \}.
\]

We omit to check that condition (4) is satisfied and move to condition (5). The left adjoint to

\[(id \times \Delta, id \times \Delta)^*: Lr(C \times D \times D, \preceq' \times \preceq \times \preceq, \gamma \times \alpha \times \alpha) \rightarrow Lr(C \times D, \preceq' \times \preceq, \gamma \times \alpha)
\]

denoted by

\[\exists (id \times \Delta): Lr(C \times D, \preceq_x, \gamma \times \alpha) \rightarrow Lr(C \times D \times D, \preceq'_x, \gamma \times \alpha \times \alpha)
\]

is defined by setting

\[\exists (id \times \Delta)(S, \preceq_x, \Phi(u)) \overset{\text{def}}{=} (\exists (id \times \Delta)(S), \preceq'_x, \exists (id \times \Delta)(\Phi(u))),
\]

where

\[\preceq'_x \overset{\text{def}}{=} \{((c, e), (N, E)) \in [\exists (id \times \Delta)(S) \times \Gamma_{\exists (id \times \Delta)(\Phi(u))}(\gamma \times \alpha \times \alpha)] \cap \preceq'_x | \exists d. \exists M. d \preceq M \& e = \Delta(d) \& E = \Delta M \& (c, d) \preceq x \langle N, M \rangle \}.
\]

Let us check that we have defined the required adjoint. Take an element

\[(U, \preceq'_x, \Psi(z)) \in Lr(C \times D \times D, \preceq'_x, \gamma \times \alpha \times \alpha).
\]

Of course we only need to check details in the middle coordinate. The action of \((id \times \Delta, id \times \Delta)^*\) on this element gives

\[(\preceq'_x)^* \overset{\text{def}}{=} \{((c, d), (N, M)) \in [(id \times \Delta)^{-1}(U) \times \Gamma_{(id \times \Delta)^*(\Psi(z))}(\gamma \times \alpha)] \cap \preceq_x | (c, d, d) \preceq'_x \langle N, M, M \rangle \}.
\]

So we need to verify that

\[\preceq'_x \subseteq (\preceq'_x)^*
\]

We check one direction. Suppose \(\preceq'_x \subseteq \preceq'_x\) and take \((c, d) \preceq_x \langle N, M \rangle\). Then \((c, d) \in S \subseteq (id \times \Delta)^{-1}(U)\) and \(\vdash \Phi(\langle N, M \rangle)\) hence \(\vdash \Psi(\langle N, M, M \rangle)\). It is clear that
\((c, d) \triangleleft_x (N, M)\). So it remains to show that \((c, d, d) \preceq (N, M, M)\). It will be enough to show \((c, d, d) \in \exists(id \times \Delta)(S)\) and \(\vdash \Phi((N, M)) \land M = M\). But this is clear, for we have \((c, d) \in S\) and \((N, M) \in \Gamma_{\Phi(u)}(\gamma \times \alpha)\). Finally, for Frobenius reciprocity, write \((C \times D, \leq_T, \top)\) for the greatest element in \(\mathcal{L}r(C \times D, \triangleleft, \gamma \times \alpha)\). Then it is easy to see that

\[
((\preceq_x^\gamma)^{\circ})^\circ = \{(c, d, d), (N, M, M)\} \in \exists(id \times \Delta) \circ (id \times \Delta)^{-1}(U) \times \\
\Gamma_{\exists(id \times \Delta) \circ (id \times \Delta)^{-1}(\psi(x))}(\gamma \times \alpha \times \alpha) \land \triangleleft_x (c, d, d) \preceq_x (N, M, M)\}
\]

\[
\leq^o_T \cap \leq^r_x .
\]

We have now shown how to define all of the adjoints and operations needed to verify that \(\mathcal{L}r\) is a FIX hyperdoctrine; we omit the remaining details. \(\square\)

5.5 Proving Existence and Disjunction Properties

We shall soon prove the Existence Property, Disjunction Property, and Standardness of \(\text{nat}\); these results were stated in Section 4.5.

The Initial Model of the FIX Logic

**Proposition 5.5.1** The FIX hyperdoctrine \(\mathcal{F}\), arising from the pure FIX logic, is (essentially) initial amongst all FIX hyperdoctrines.

**Proof** This is immediate from the definition of FIX hyperdoctrine morphism. \(\square\)

We shall need the following observations: Using the initiality of \(\mathcal{F}\), we see that there are FIX hyperdoctrine morphisms \(\llbracket - \rrbracket\) and \(I\), together with obvious projections \(\pi\) and \(\pi'\) where

\[
\llbracket - \rrbracket : \mathcal{F} \rightarrow \omega Cpo \\
\pi : \mathcal{L}r \rightarrow \omega Cpo
\]

\[
I : \mathcal{F} \rightarrow \mathcal{L}r \\
\pi' : \mathcal{L}r \rightarrow \mathcal{F}.
\]

These FIX hyperdoctrine morphisms satisfy the following commutative diagrams:

\[
\begin{array}{ccc}
\mathcal{F} & \xrightarrow{id} & \mathcal{F} \\
\downarrow I & & \downarrow \pi \\
\mathcal{L}r & \xrightarrow{\pi'} & \omega Cpo
\end{array}
\]

\[
\begin{array}{ccc}
\mathcal{F} & \xrightarrow{id_\alpha} & \mathcal{F}(\alpha) \\
\downarrow I_\alpha & & \downarrow \llbracket - \rrbracket_\alpha \\
\mathcal{L}r(\llbracket \alpha \rrbracket, \triangleleft_{\alpha}, \alpha) & \xrightarrow{\pi_\alpha} & \mathcal{I}(\llbracket \alpha \rrbracket)
\end{array}
\]

94
The Disjunction Property

We prove Theorem 4.5.5. First note that the closed term \( E : \alpha + \beta \) corresponds to a morphism \( E : \text{unit} \to \alpha + \beta \) in \( \mathcal{F} \). The action of the base functor component of \( \mathcal{I} : \mathcal{F} \to \mathcal{Lr} \) on this morphism, using the above commutative diagrams, is

\[
\mathcal{I}(E) = ([\alpha], E) : (1, \trianglelefteq_{\text{unit}}, \text{unit}) \to ([\alpha] + [\beta], \trianglelefteq_{\alpha+\beta}, \alpha + \beta).
\]

Also, the following square commutes:

\[
\begin{array}{c}
\mathcal{F}(\alpha + \beta) \xrightarrow{\mathcal{I}_{\alpha+\beta}} \mathcal{Lr}([\alpha] + [\beta], \trianglelefteq_{\alpha+\beta}, \alpha + \beta) \\
\downarrow \quad \downarrow \quad \downarrow \quad \downarrow \\
\mathcal{F}(\text{unit}) \xrightarrow{\mathcal{I}_{\text{unit}}} \mathcal{Lr}(1, \trianglelefteq_{\text{unit}}, \text{unit})
\end{array}
\]

The theorem follows by observing the effect of the two possible routes of the square. Let \( z \) be a variable of type \( \alpha + \beta \), and consider \( (\Phi + \Psi)(z) \in \mathcal{F}(\alpha + \beta) \). Then we have

\[
\mathcal{I}_{\text{unit}}(E^*((\Phi + \Psi)(z))) = \mathcal{I}((\Phi + \Psi)(E))
\]

\[
= ([\Phi + \Psi](E)], \trianglelefteq_{\text{unit}}, (\Phi + \Psi)(E))
\]

where because \( \vdash (\Phi + \Psi)(E) \) by hypothesis and \( \mathcal{I}_{\text{unit}} \) preserves greatest elements, the relation \( \trianglelefteq_{\text{unit}} \) must be non-empty. Also, we have

\[
([\alpha], E)^*(\mathcal{I}_{\alpha+\beta}((\Phi + \Psi)(z))) = ([\alpha], E)^*([z.(\Phi + \Psi)(z)], \trianglelefteq_{\alpha+\beta}, (\Phi + \Psi)(z))
\]

\[
= ([\alpha]^{-1}([z.(\Phi + \Psi)(z)], \trianglelefteq_{\alpha+\beta}^*, (\Phi + \Psi)(E))
\]

where

\[
\trianglelefteq_{\alpha+\beta}^* = \{ (\ast, id_{\text{unit}}) \in ([\alpha]^{-1}([z.(\Phi + \Psi)(z)])) \times \Gamma_{(\Phi + \Psi)(E)}(\text{unit}) \} \cap \trianglelefteq_{\text{unit}}
\]

\[
\mathcal{I}(E)(\ast) \trianglelefteq_{\alpha+\beta} E \circ id.
\]

But this relation is exactly \( \trianglelefteq_{\text{unit}} \), hence is non-empty, yielding \( \mathcal{I}(E)(\ast) \trianglelefteq_{\alpha+\beta} E \) which implies \( \mathcal{I}(E)(\ast) \trianglelefteq_{\alpha+\beta} E \). By definition of the relation \( \trianglelefteq_{\alpha+\beta} \) this means without loss of generality there is a global element \( M \in \Gamma(\alpha) \), that is a closed term \( M \), for which \( \vdash E = _{\alpha+\beta} \lnl(M) \), and from this we may derive \( \vdash \Phi(M) \) using Proposition 4.5.1.
The Existence Property

We prove Theorem 4.5.4. Take a proposition \( \Diamond (e, \Phi) \in \mathcal{F}(T \alpha) \) and use the square

\[
\begin{array}{ccc}
\mathcal{F}(T \alpha) & \xrightarrow{I_{T \alpha}} & \mathcal{L}r([\alpha]_\perp, \triangleleft_{T \alpha}, T \alpha) \\
E^* & \downarrow & (\lfloor E \rfloor, E)^* \\
\mathcal{F}(\text{unit}) & \xrightarrow{I_{\text{unit}}} & \mathcal{L}r(1, \triangleleft_{\text{unit}}, \text{unit})
\end{array}
\]

As above, this yields

\[
\triangleleft_{\text{unit}} = \triangleleft_{T \alpha}^\# = \{(\star, id) \in [\lfloor E \rfloor^{-1}(\lfloor e \circ (e, \Phi) \rfloor) \times \Gamma_{\Diamond (e, \Phi)(\text{unit})}) \cap \triangleleft_{\text{unit}} \lfloor E \rfloor(\star) \leq_{T \alpha} E\}.
\]

This has to be non empty and so \([E](\star) \leq_{T \alpha} E\), which implies \([E](\star) \triangleleft_{T \alpha} E\). By assumption we have \(\vdash \Diamond (E, \Phi)\) and therefore \(\{\star\} = [\lfloor E \rfloor^{-1}\eta([x, \Phi(x)])\}\) implying that \([E](\star)\) is not bottom. Hence there is some closed \(M\) for which \(\vdash E =_{T \alpha} \text{Val}(M)\) and using Proposition 4.5.1 we have \(\vdash \Phi(M)\).

A Formal Adequacy of the FIX Logic

We finish this section by remarking that the Existence Property expresses a formal adequacy of the FIX logic. Indeed, we have the following

**Corollary 5.5.2** Given a closed term \(E\) of type \(T \alpha\), it is provably equal to a value \(\text{Val}(M)\), where \(M\) is a closed term of type \(\alpha\), if and only if the \(\omega Cpo\) interpretation \([E] \in [T \alpha] = [\alpha]_\perp\) is not \(\perp\).

**Proof** Immediate from the proof of the Existence Property. ⧫

5.6 Proving Standardness of the Natural Number Type

We prove Theorem 4.5.6. Let \(N\) be a closed term of type \(\text{nat}\). Using the square

\[
\begin{array}{ccc}
\mathcal{F}(\text{nat}) & \xrightarrow{I_{\text{nat}}} & \mathcal{L}r(\text{nat}, \triangleleft_{\text{nat}}, \text{nat}) \\
N^* & \downarrow & ([N], N)^* \\
\mathcal{F}(\text{unit}) & \xrightarrow{I_{\text{unit}}} & \mathcal{L}r(1, \triangleleft_{\text{unit}}, \text{unit})
\end{array}
\]

96
and arguing the same way as in the previous section, we conclude that \( \llbracket N \rrbracket(*) \lesssim_{\text{nat}} N \) and from this we deduce \( +N =_{\text{nat}} \text{Suc}^n(0) \), using the definition of the \( \lesssim_{\text{nat}} \) relation in the NNO of \( \mathcal{L}r \).
Chapter 6
Applications of the FIX Logic

6.1 Introduction

In this chapter we shall define the syntax and operational semantics of two little programming languages, both of which are closely allied to Plotkin's PCF. PCF is an acronym for Programming Computable Functions. In essence, the syntax of PCF is that of simply typed lambda calculus (with ground types just the natural numbers and booleans) which has been enriched with explicit operations for arithmetic, a conditional at ground types and fixpoint operators. This syntax is then equipped with a call by name operational semantics, giving rise to the language PCF. PCF was first investigated by Plotkin and the results appear in [Plo77].

The two languages we investigate here, which we call QL and HPCF, resemble PCF in that their syntax consists essentially of simply typed lambda calculus with extra arithmetical, procedural and fixpoint features. They differ in having conditionals at higher types. The syntax of QL, while similar to that of PCF, makes use of higher order metaconstants. QL has recursive function declarations instead of fixpoint operators and the operational semantics is call by value. HPCF has a call by name operational semantics and apart from conditionals at higher types is identical to PCF.

We shall specify the syntax and semantics of these languages, then give a translation into a suitable FIX theory. For each language we state two adequacy results, one for static semantics and one for dynamic semantics, which shows that the translation preserves the structure of the original language. We emphasise that both QL and HPCF are no more than very simple adaptations of Plotkin’s PCF. The intention of this chapter is just to investigate how well suited the FIX logic is for interpreting and reasoning about two quite standard languages. The FIX logic can be viewed as a metalogic in which we interpret both QL and HPCF; for an account of this style of programming language analysis see [Plo85].

6.2 The Language QL

We define the language QL by specifying the basic syntax of types and raw expressions; this syntax will then be given a static and dynamic semantics.
The Types and Expressions of QL

The types of QL are given by the grammar:

\[ \sigma ::= \text{bool} \mid \text{nat} \mid \sigma \rightarrow \sigma \]

The (raw) expressions of QL are given by the grammar:

\[
\begin{align*}
m & ::= x \quad \text{variables} \\
    & \mid \mathbf{tt} \quad \text{truth} \\
    & \mid \mathbf{ff} \quad \text{falsity} \\
    & \mid k_n \quad \text{natural numbers} \\
    & \mid C_o(b,m,n) \quad \text{conditional} \\
    & \mid S(m) \quad \text{successor} \\
    & \mid P(m) \quad \text{predecessor} \\
    & \mid Z(m) \quad \text{zero test} \\
    & \mid mn \quad \text{application} \\
    & \mid \lambda x:\sigma.m \quad \text{function definition} \\
    & \mid R_{\tau,\sigma}(m,n) \quad \text{recursive functions}
\end{align*}
\]

The Static Semantics of QL

The static semantics assigns types to expressions in context. Each judgement takes the form \( \Gamma \vdash m: \sigma \). The rules for deriving these judgements are given below. The context \( \Gamma \) consists of a list of typed variables (the variables are assumed distinct). Variables are bound in the usual way by lambda abstractions and recursive function declarations. Given a QL expression in context, \( \Gamma \vdash m: \sigma \), it is easy to see that the free variables of \( m \) all occur in \( \Gamma \), and that the type \( \sigma \) assigned to the raw QL term \( m \) is unique. The types \text{nat} and \text{bool} will be referred to as \textit{ground} types.

<table>
<thead>
<tr>
<th>Variables</th>
<th>( \Gamma, x: \sigma, \Gamma' \vdash x: \sigma )</th>
</tr>
</thead>
<tbody>
<tr>
<td>Constants</td>
<td>( \Gamma \vdash \mathbf{tt}: \text{bool} ) \quad ( \Gamma \vdash \mathbf{ff}: \text{bool} ) \quad ( \Gamma \vdash k_n: \text{nat} )</td>
</tr>
<tr>
<td>Conditional</td>
<td>( \Gamma \vdash b: \text{bool} ) \quad ( \Gamma \vdash m: \sigma ) \quad ( \Gamma \vdash n: \sigma ) \quad ( \Gamma \vdash C_o(b,m,n): \sigma )</td>
</tr>
<tr>
<td>Arithmetic</td>
<td>( \Gamma \vdash m: \text{nat} ) \quad ( \Gamma \vdash m: \text{nat} ) \quad ( \Gamma \vdash m: \text{nat} ) \quad ( \Gamma \vdash S(m): \text{nat} ) \quad ( \Gamma \vdash P(m): \text{nat} ) \quad ( \Gamma \vdash Z(m): \text{bool} )</td>
</tr>
</tbody>
</table>
Functions

\[
\begin{align*}
\Gamma \vdash m : \sigma \rightarrow \tau & \quad \Gamma \vdash n : \sigma \\
\Gamma \vdash mn : \tau \\
\Gamma, x : \sigma \vdash m : \tau & \quad \Gamma \vdash \lambda x : \sigma . m : \sigma \rightarrow \tau
\end{align*}
\]

Recursive Functions

\[
\begin{align*}
\Gamma, f : \sigma \rightarrow \sigma' , x : \sigma \vdash m : \sigma' & \quad \Gamma \vdash n : \sigma \\
\Gamma \vdash R_{\sigma, \sigma'}(m, n) : \sigma'
\end{align*}
\]

The Dynamic Semantics of QL

We call a QL expression \( m \) closed if \( \vdash m : \sigma \) is derivable for some (necessarily unique) type \( \sigma \). The canonical QL expressions comprise the subset of closed expressions given by the grammar:

\[
c ::= tt \mid ff \mid k_n \mid \lambda x : \sigma . m
\]

We now give the syntax of QL a call by value dynamic semantics via an evaluation relation, which will take the form \( m \rightarrow c \), where \( m \) and \( c \) are closed QL expressions and \( c \) is canonical. The rules for generating the evaluation relation are given below:

Canonical Forms

\[
c \quad \text{canonical} \\
\quad c \rightarrow c
\]

Conditionals

\[
b \rightarrow tt \quad m \rightarrow c \\
b \rightarrow ff \quad n \rightarrow c \\
C_{\sigma}(b, m, n) \rightarrow c \\
C_{\sigma}(b, m, n) \rightarrow c
\]

Arithmetic

\[
m \rightarrow k_n \\
S(m) \rightarrow k_{n+1} \\
m \rightarrow k_0 \\
Z(m) \rightarrow tt \\
Z(m) \rightarrow ff
\]

Functions

\[
m \rightarrow \lambda x : \sigma . m' \\
n \rightarrow c' \\
m'[c'/x] \rightarrow c \\
mn \rightarrow c
\]

Recursive Functions

\[
n \rightarrow c' \\
m[\lambda x : \sigma . R_{\sigma, \sigma'}(m, x)/f, c'/x] \rightarrow c \\
R_{\sigma, \sigma'}(m, n) \rightarrow c
\]
It is easy to see that the dynamic semantics is deterministic and if $m \rightarrow c$ then $m$ and $c$ have the same type.

6.3 Translation of QL into the FIX Logic

We shall give a translation of QL into a theory over FIX. We aim to give an interpretation of the language QL which will preserve all of its structure and properties. In fact the pure FIX logic will interpret QL; more formally, the FIX theory we consider consists simply of the FIX signature with no basic function symbols or relation symbols, together with no extralogical axioms. We shall not be too formal and simply refer to the FIX logic. The first step is to translate the static semantics of QL into suitable judgements in the FIX logic.

Interpretation of the Static Semantics

For each expression in context, $x_1: \sigma_1, \ldots, x_n: \sigma_n \vdash m: \sigma$, we give a a term in context of FIX, and we think of this process as a translation of QL into FIX. The static typing judgement $x_1: \sigma_1, \ldots, x_n: \sigma_n \vdash m: \sigma$ is translated to

$$x_1: \llbracket \sigma_1 \rrbracket^v, \ldots, x_n: \llbracket \sigma_n \rrbracket^v \vdash \llbracket m \rrbracket^v(\bar{x}): T\llbracket \sigma \rrbracket^v,$$

where for any term $m$ in a context of $n$ variables $\{x_1, \ldots, x_n\}$, $\llbracket m \rrbracket^v$ is an expression of the abstract syntax generated from the pure FIX logic with arity TERM and for which $\text{FV}(\llbracket m \rrbracket^v) = \{u_1, \ldots, u_n\}$. Given a closed QL expression (in context) $\vdash m: \sigma$, this is of course translated to a judgement $\vdash \llbracket m \rrbracket^v: T\llbracket \sigma \rrbracket^v$. Note that the superscript $v$ on the semantic bracket $\llbracket - \rrbracket^v$ refers to the fact that we are specifying a translation of a call by value language. We shall often refer informally to a call by value translation. In order to specify the translation, we shall define expressions of the abstract syntax generated from the object level signature of FIX which have arity TERM $\rightarrow$ TERM and which we shall denote by $\text{Pred}$ and $\text{Zero}$. The (representatives for these) expressions are (using $\eta$ equality in the meta $\lambda$ calculus) defined by

$$\text{Pred}(n) \overset{\text{def}}{=} \text{Snd}((x. (\text{Suc}(\text{Fst}(x))), \text{Fst}(x)))^n(\langle O, O \rangle)$$

$$\text{Zero}(n) \overset{\text{def}}{=} (x. \text{lnr}_{\text{unit}}(\langle \rangle))^n(\text{lnl}_{\text{unit}}(\langle \rangle))$$

Note that the judgements $n: \text{nat} \vdash \text{Pred}(n): \text{nat}$ and $n: \text{nat} \vdash \text{Zero}(n): \text{unit} + \text{unit}$ are FIX terms in context; moreover, it is not difficult to see that $\text{Pred}$ and $\text{Zero}$ have the properties we would expect of them. We also make the definition

$$\text{Fix}_\alpha(f) \overset{\text{def}}{=} \text{lt}_\alpha(e. \text{Let}(e, x. fx), \sigma(\omega))$$

for which it is immediate that $f: T\alpha \rightarrow T\alpha \vdash \text{Fix}_\alpha(f): T\alpha$ is a FIX term in context.

The translation of QL into FIX is given below:

- $\llbracket \text{nat} \rrbracket^v \overset{\text{def}}{=} \text{nat}$
• $\llbracket bool\rrbracket^v \overset{\text{def}}{=} unit + unit$

• $\llbracket \sigma \rightarrow \tau \rrbracket^v \overset{\text{def}}{=} \llbracket \sigma \rrbracket^v \rightarrow T[\tau]^v$

• $\llbracket x \rrbracket^v \overset{\text{def}}{=} Val(u)$ where $u$ is a meta variable.

• $\llbracket \text{tt} \rrbracket^v \overset{\text{def}}{=} Val(\text{ln}_\text{unit}(\langle \rangle))$

• $\llbracket \text{ff} \rrbracket^v \overset{\text{def}}{=} Val(\text{ln}_\text{unit}(\langle \rangle))$

• $\llbracket \text{kn} \rrbracket^v \overset{\text{def}}{=} Val(\text{Suc}^n(0))$

• $\llbracket C_\sigma(b, m, n) \rrbracket^v \overset{\text{def}}{=} \text{Let}(\llbracket b \rrbracket^v, x, \{y, \llbracket m \rrbracket^v, y, \llbracket n \rrbracket^v\}(x))$

• $\llbracket S(n) \rrbracket^v \overset{\text{def}}{=} \text{Let}(\llbracket n \rrbracket^v, x, Val(\text{Suc}(x)))$

• $\llbracket P(n) \rrbracket^v \overset{\text{def}}{=} \text{Let}(\llbracket n \rrbracket^v, x, Val(\text{Pred}(x)))$

• $\llbracket Z(n) \rrbracket^v \overset{\text{def}}{=} \text{Let}(\llbracket n \rrbracket^v, x, Val(\text{Zero}(x)))$

• $\llbracket mn \rrbracket^v \overset{\text{def}}{=} \text{Let}(\llbracket m \rrbracket^v, f, \text{Let}(\llbracket n \rrbracket^v, x, f x))$

• $\llbracket \lambda x: \sigma.m \rrbracket^v \overset{\text{def}}{=} Val(\lambda_{\sigma}^{[m]}(x, \llbracket m \rrbracket^v))$

• $\llbracket R_{\sigma,\sigma}(m, n) \rrbracket^v \overset{\text{def}}{=} \text{Let}(\llbracket n \rrbracket^v, y, Y_{\sigma}^{[n]}(\lambda f, (\lambda (x, \llbracket m \rrbracket^v)))(y))$

**Interpretation of the Dynamic Semantics**

Clearly the minimal requirement of an interpretation of the dynamics semantics of QL is soundness, namely that if $m \rightarrow c$ then we have $\vdash \llbracket m \rrbracket^v = \llbracket c \rrbracket^v$ where the latter equality holds in FIX. Further, it would be pleasing if whenever $\vdash \llbracket m \rrbracket^v = \llbracket c \rrbracket^v$, there is a canonical $c'$ for which $m \rightarrow c'$ and $\vdash \llbracket c' \rrbracket^v = \llbracket c \rrbracket^v$, that is to say that FIX is computationally adequate for interpreting QL. We shall soon see that this is indeed the case, and in order to do this we shall need a little additional notation. For canonical closed terms $c$ of QL, note that the interpretation takes the form $\llbracket c \rrbracket^v \equiv Val(\llbracket c \rrbracket)$ and we shall take this as an informal definition of $\llbracket c \rrbracket$. We translate the dynamic semantics of QL into judgements in FIX simply by taking each instance of the evaluation relation $m \rightarrow c$ to the judgement $\vdash \llbracket m \rrbracket^v = \llbracket c \rrbracket^v$.

**6.4 Adequacy Results for QL**

**Static Adequacy for QL**

**Proposition 6.4.1** ["QL Static Adequacy"] The interpretation of the static semantics of QL in FIX is adequate, in the sense that $x: \sigma; \vdash m: \sigma$ is a well formed QL
expression in context iff

\[ x_i; [\sigma_i]^v \vdash \bar{a}, [m]^v(\bar{x}): T[\sigma]^v \]

is derivable in FIX.

**Proof** Both directions proceed by structural induction. We give one example, for the backwards direction.

*(Case \( m \) is \( R(m, n) *) From the definition of \( [R(m, n)]^v \), the FIX logic rules and the induction hypothesis, we have

\[ x_i; \sigma_i, f: \sigma' \rightarrow \sigma, x: \sigma' \vdash m: \sigma \text{ and } x_i; \sigma_i \vdash n: \sigma', \]

from which \( x_i; \sigma_i \vdash R(m, n): \sigma \) is immediate. \( \square \)

**Dynamic Adequacy of QL**

We shall require a Lemma based on Plotkin’s methods given in [Plo85]. We write \( D(-) \) for the composition \( \llbracket - \rrbracket \circ \bar{u}, \llbracket - \rrbracket^v(\bar{x}): \text{QL} \rightarrow \text{FIX} \rightarrow \omega Cpo \) where \( \llbracket - \rrbracket \) is the standard domain theoretic semantics of FIX. We define a relation \( \triangleleft_\sigma \) between elements \( d \in D(\sigma) \) and canonical forms \( \vdash c: \sigma \) by induction on the structure of \( \sigma \).

In the definition which follows, \( \triangleleft_\sigma \) is the relation between elements \( e \in D(\sigma)_\perp \) and closed QL terms \( \vdash m: \sigma \) defined in terms of \( \triangleleft_\sigma \) by asking that \( e \triangleleft_\sigma m \) iff \( \forall d \in D(\sigma). e = [d] \supseteq \exists c. m \rightarrow c \& d \triangleleft_\sigma c \). We define:

- \( i(*) \triangleleft_\text{boot} \, \text{tt} \) and \( j(*) \triangleleft_\text{boot} \, \text{ff} \) where \( i, j: 1 \rightarrow 1 + 1 \) are coproduct insertions.
- \( n \triangleleft_\text{nat} k_n \) where \( n \in \mathbb{N} \).
- \( f \triangleleft_\sigma \lambda x: \sigma.m \) iff \( \forall d \in D(\sigma). \forall c: \sigma.d \triangleleft_\sigma c \supseteq f(d) \triangleleft_\sigma (\lambda x: \sigma.m).c \).

With this, we have

**Lemma 6.4.2** Let \( x_1; \sigma_1, \ldots, x_n; \sigma_n \vdash m: \sigma \) be a QL term in context and suppose that for \( i = 1, \ldots, n \) we have \( d_i \in D(\sigma_i)_\perp \) \( \vdash c_i: \sigma_i \) and \( d_i \triangleleft_\sigma c_i \). Then the continuous function \( D(\Gamma \vdash m): D(\sigma_1) \times \ldots \times D(\sigma_n) \rightarrow D(\sigma)_\perp \) satisfies \( D(\Gamma \vdash m)(\bar{d}) \triangleleft_\sigma m[\bar{c}/\bar{x}] \).

**Proof** The proof proceeds by induction on the structure of \( m \). We illustrate the proof with two cases

*(Case \( m \) is \( \lambda x: \sigma.m \)): Suppose that the conditions of the lemma are satisfied. Then we need to show that \( D(\Gamma \vdash \lambda x: \sigma.m)(\bar{d}) \triangleleft_\sigma \lambda x: \sigma.m[\bar{c}/\bar{x}] \). Using the definition of \( D(-) \) we can show that \( D(\Gamma \vdash \lambda x: \sigma.m) = \iota \circ \text{cur}(D(\Gamma, x: \sigma \vdash m)) \) where

\[ \iota: D(\sigma) \rightarrow D(\tau)_\perp \rightarrow (D(\sigma) \rightarrow D(\tau)_\perp)_\perp. \]

Hence \( D(\Gamma \vdash \lambda x: \sigma.m)(\bar{d}) = [\text{cur}(D(\Gamma, x: \sigma \vdash m))(\bar{d})] \). By definition of the \( \triangleleft_\sigma \) relation we show that \( \text{cur}(D(\Gamma, x: \sigma \vdash m))(\bar{d}) \triangleleft_\sigma \lambda x: \sigma.m[\bar{c}/\bar{x}] \); thus if \( d \triangleleft_\sigma c \) it remains
to show \( \text{cur}(D(\Gamma \vdash \lambda x: \sigma.m))(\vec{d})(d) \leq_\tau (\lambda x: \sigma.m[\vec{c}/\vec{x}])c \). By the induction hypothesis, 
\( D(\Gamma, x: \sigma \vdash m)[\vec{d}, d] \leq_\tau m[\vec{c}/\vec{x}, c/x] \) and so \( m[\vec{c}/\vec{x}, c/x] \Rightarrow c' \) for some \( c' \) provided that \( D(\Gamma \vdash \lambda x: \sigma.m)[\vec{d}](d) \) is not \( \bot \). But then \( (\lambda x: \sigma.m[\vec{c}/\vec{x}])c \Rightarrow c' \) and we are done.

(Case \( \text{mn} \)): We need to show that \( D(\Gamma \vdash \text{mn})[\vec{d}] \leq_\tau m[\vec{c}/\vec{x}]n[\vec{c}/\vec{x}] \) where, say, \( \Gamma \vdash m: \sigma \rightarrow \tau \) and \( \Gamma \vdash n: \sigma \). Suppose that \( D(\Gamma \vdash \text{mn})[\vec{d}] \) is not \( \bot \). One can check that neither are \( D(\Gamma \vdash m)[\vec{d}] \) or \( D(\Gamma \vdash n)[\vec{d}] \); let us write \( [f] \) and \( [d] \) for these. By the induction hypothesis we have \( [f] \leq_{\sigma \rightarrow \tau} m[\vec{c}/\vec{x}] \) and \( [d] \leq_\sigma n[\vec{c}/\vec{x}] \). Hence \( m[\vec{c}/\vec{x}] \Rightarrow \lambda x: \sigma.m' \) and \( n[\vec{c}/\vec{x}] \Rightarrow c \). This leads to \( f(d) \leq_\tau (\lambda x: \sigma.m')c \) and from the original supposition there is some \( c' \) for which \( (\lambda x: \sigma.m')c \Rightarrow c' \). Thus we may deduce \( m'[c/x] \Rightarrow c' \) and conclude \( m[\vec{c}/\vec{x}]n[\vec{c}/\vec{x}] \Rightarrow c' \). \( \square \)

We shall also need the following Lemma:

**Lemma 6.4.3** With the call by value interpretation of QL, and \( x: \sigma \vdash m: \tau, \vdash c: \sigma \) QL terms in context with \( c \) canonical, we have

\[
\vdash [m[c/x]]^v = [m]^v[[c]/u],
\]

where \( [x]^v \overset{\text{def}}{=} \text{Val}(u) \) and \( [[c]/u] \) means substitution in the meta \( \lambda \) calculus.

**Proof** N.B. Recall Section 0.3 of Chapter 0. The proof is a trivial structural induction on \( m \). We illustrate with one example.

(Case \( m \) is \( R(m, n) \)):

\[
\begin{align*}
\vdash [R(m, n)[c/y]]^v & = \text{Let}([[n[c/y]]^v, u.\lambda (\lambda x. [m[c/y]]^v))u) \\
\text{which by induction is} \quad & = \text{Let}([[n]^v, u.\lambda (\lambda x. [m]^v))u) [c]/y) \\
\quad & = [R(m, n)]^v[[c]/y].
\end{align*}
\]

\( \square \)

**Theorem 6.4.4** ["QL Dynamic Adequacy"] The interpretation of QL in the FIX logic is *computationally adequate*; more precisely, given closed QL terms \( m \) and \( c \) for which \( c \) is canonical, then \( m \Rightarrow c \) implies \( \vdash [m]^v = [c]^v \), and \( \vdash [m]^v = [c]^v \) implies there is some canonical \( c' \) for which \( m \Rightarrow c' \).

**Proof** The proof in the forwards direction proceeds by induction on the derivation of \( m \Rightarrow c \); we give details for the cases of application and recursive function terms.

(Case \( mn \Rightarrow c \)): Using minimality of \( \Rightarrow \) and the induction hypothesis, we obtain

\[
\begin{align*}
\vdash [m]^v & = \text{Val}(\lambda x. [m]^v) \\
\vdash [n]^v & = \text{Val}(c') \\
\vdash [m'[c'/x]]^v & = \text{Val}(c).
\end{align*}
\]

105
Thus we have

\[ \Gamma \vdash [m n]^v = \text{Let}([n]^v, f. \text{Let}([n]^v, x.f x)) \]
\[ = \lambda(x.[w]^v)[c'] \]
\[ = [w'][^v][c'/x] \]

which by Lemma 6.4.3 = [c]^v,

as required.

(Case \( R(m, n) \rightarrow c \)): Using minimality of \( \rightarrow \) and the induction hypothesis, we obtain

\[ \Gamma \vdash [n]^v = \text{Val}([c']) \]
\[ \Gamma \vdash [m[\lambda x: \sigma.R(m, x)/f, c'/x]]^v = \text{Val}([c]). \]

Let us put \( M \overset{\text{def}}{=} \lambda(f.\lambda(x.[m]^v)) \) and note that

\[ \Gamma \vdash [\lambda x: \sigma.R(m, x)]^v = \text{Val}(\lambda(x.\text{Y}(M) x)) \]
\[ = \text{Val}(\text{Y}(M)). \]

Thus we have

\[ \Gamma \vdash [R(m, n)]^v = \text{Let}([n]^v, y.\text{Y}(\lambda(f.\lambda(x.[m]^v)))y) \]
\[ = \lambda(f.\lambda(x.[m]^v))[Y(M)/f][c'] \]
\[ = \lambda(x.[m]^v)[Y(M)/f][c'] \]
\[ = [m][Y(M)/f][c'/x] \]
\[ = [m][\lambda x: \sigma.R(m, x)/f, [c'/x] \]

which by Lemma 6.4.3 = [c]^v,

and so we are done.

For the converse direction, suppose that \( \Gamma \vdash [m]^v =_v [c]^v \). We have \([m]^v = \text{Val}([c]) \) and hence it is the case that \( D(\Gamma) \rightarrow (\ast) \) is not \( \bot \), say \([d] \). Appeal to Lemma 6.4.2 to deduce that \([d] \leq_s m \) and hence there is some canonical \( c' \) for which \( m \rightarrow c' \) by the definition of \( \leq_s \).

6.5  A Further PCF style language, HPCF

We define the language HPCF by specifying the basic syntax of types and raw expressions; this syntax will then be given a static and dynamic semantics.

The Types and Expressions of HPCF

The types of HPCF are given by the grammar:

\[ \sigma ::= \text{bool} | \text{nat} | \sigma \rightarrow \sigma \]
The (raw) expressions of HPCF are given by the grammar:

\[ m ::= x \quad \text{variables} \]
\[ \text{tt} \quad \text{truth} \]
\[ \text{ff} \quad \text{falsity} \]
\[ k_n \quad \text{natural numbers} \]
\[ C_\varphi \quad \text{conditional} \]
\[ S \quad \text{successor} \]
\[ P \quad \text{predecessor} \]
\[ Z \quad \text{zero test} \]
\[ Y_\varphi \quad \text{fixpoints} \]
\[ mn \quad \text{application} \]
\[ \lambda x: \sigma. m \quad \text{function definition} \]

The Static Semantics of HPCF

**Variables**

\[ \frac{}{\Gamma, x: \sigma, \Gamma' \vdash x: \sigma} \]

**Constants**

\[ \Gamma \vdash \text{tt}: \text{bool} \quad \Gamma \vdash \text{ff}: \text{bool} \quad \Gamma \vdash k_n: \text{nat} \]

**Conditional**

\[ \Gamma \vdash C_\varphi: \text{bool} \rightarrow (\sigma \rightarrow (\sigma \rightarrow \sigma)) \]

**Arithmetic**

\[ \Gamma \vdash S: \text{nat} \rightarrow \text{nat} \quad \Gamma \vdash P: \text{nat} \rightarrow \text{nat} \quad \Gamma \vdash Z: \text{nat} \rightarrow \text{bool} \]

**Fixpoints**

\[ \Gamma \vdash Y_\varphi: (\sigma \rightarrow \sigma) \rightarrow \sigma \]

**Functions**

\[ \frac{\Gamma \vdash m: \sigma \rightarrow \tau \quad \Gamma \vdash n: \sigma}{\Gamma \vdash mn: \tau} \quad \frac{\Gamma, x: \sigma \vdash m: \tau}{\Gamma \vdash \lambda x: \sigma. m: \sigma \rightarrow \tau} \]
The Dynamic Semantics of HPCF

The canonical HPCF expressions consist of the subset of closed expressions given by the grammar:

\[ c ::= \text{tt} | \text{ff} | \sigma \cdot c | k_n | S | P | Z | Y_{\sigma} | \lambda x : \sigma . m | c \cdot b | C_{\sigma} b \]

We now give the syntax of HPCF a call by name dynamic semantics. Apart from conditionals at higher types, HPCF is in every respect identical to Plotkin’s language PCF. The dynamic semantics will be presented using an evaluation relation just as for QL:

### Canonical Forms

\[
\frac{c \text{ canonical}}{c \Rightarrow c}
\]

### Conditionals

\[
\frac{m \Rightarrow \sigma}{\sigma \cdot b \Rightarrow \sigma \cdot b} \quad \frac{m \Rightarrow \sigma \cdot b \cdot m' \quad b \Rightarrow \text{tt} \quad m' \Rightarrow c}{\text{mn} \Rightarrow c} \quad \frac{m \Rightarrow \sigma \cdot b \cdot n \Rightarrow c}{l \Rightarrow \sigma} \quad \frac{b \Rightarrow \text{ff} \quad n \Rightarrow c}{1 \cdot \text{mn} \Rightarrow c}
\]

### Arithmetic

\[
\frac{m \Rightarrow S \quad n \Rightarrow k_n}{\text{mn} \Rightarrow k_{n+1}} \quad \frac{m \Rightarrow P \quad n \Rightarrow k_{n+1}}{\text{mn} \Rightarrow k_0} \quad \frac{m \Rightarrow P \quad n \Rightarrow k_0}{\text{mn} \Rightarrow k_0} \quad \frac{m \Rightarrow Z \quad n \Rightarrow k_0}{\text{mn} \Rightarrow \text{tt}} \quad \frac{m \Rightarrow Z \quad n \Rightarrow k_{n+1}}{\text{mn} \Rightarrow \text{ff}}
\]

### Fixpoints

\[
\frac{m \Rightarrow Y_{\sigma}}{\text{mn} \Rightarrow c} \quad \frac{nY_{\sigma} \cdot n \Rightarrow c}{\text{mn} \Rightarrow c}
\]

### Functions

\[
\frac{m \Rightarrow \lambda x : \sigma . m'}{\text{mn} \Rightarrow c} \quad \frac{m'[n/x] \Rightarrow c}{\text{mn} \Rightarrow c}
\]

**Remark 6.5.1** Plotkin originally specified the operational semantics of PCF via a single step reduction relation of the form \( m \rightarrow n \) where \( m \) and \( n \) are closed terms. Clearly HPCF could be given an operational semantics in the same way: for details of the original specification of Plotkin’s PCF in this style of semantics see [Plo77]. We omit the details, but remark that presenting HPCF in this style would lead to:
Proposition 6.5.2 Let \( m \) and \( c \) be closed HPCF terms with \( c \) canonical. Then \( m \Rightarrow c \) iff \( m \Rightarrow^* c \), where \( \Rightarrow^* \) is the reflexive transitive closure of \( \Rightarrow \). \( \Box \)

This can be proved succinctly through:

Lemma 6.5.3 If \( m \Rightarrow n \) then for all closed canonical \( c \), we have \( n \Rightarrow c \) implies \( m \Rightarrow c \). \( \Box \)

6.6 Translation of HPCF into the FIX Logic

Interpretation of the Static Semantics

For each expression in context, \( x_i : \sigma_i \vdash m : \sigma \) of HPCF, we give a translation into a term in context of FIX. The static typing judgement \( x_i : \sigma_1, \ldots, x_n : \sigma_n \vdash m : \sigma \) is translated to

\[
x_i : T[\sigma_i]^n, \ldots, x_n : T[\sigma_n]^n \vdash \overline{u}[m](\overline{x}) : T[\sigma]^n.
\]

The translation of HPCF into FIX is given below:

- \( \overline{\text{n}} \overline{\text{at}} \equiv \text{nat} \)
- \( \overline{\text{b}} \equiv \text{unit + unit} \)
- \( \overline{\sigma 
\rightarrow \tau} \equiv T[\sigma]^n 
\rightarrow T[\tau]^n \)
- \( \overline{x} \equiv u \) where \( u \) is a meta variable.
- \( \overline{\text{t}t} \equiv \text{Val(\text{ln}_\text{unit}(\{}))} \)
- \( \overline{\text{f}f} \equiv \text{Val(\text{lnr}_\text{unit}(\{}))} \)
- \( \overline{\text{c}c} \equiv \text{Val(\text{Suc}(\{}))} \)
- \( \overline{\text{b}0} \equiv \text{Val(\lambda_T[\text{bool}]^n.b.\text{Val(\lambda_T[\sigma]^n.(z.\text{Val(\lambda_T[\sigma]^n.(z'.\text{Let (b, x, \{y, z, y', z'}(x) ... \})}}))} \)
- \( \overline{\text{s}s} \equiv \text{Val(\lambda_T[\text{nat}]^n.(y.\text{Let (y, x.\text{Val(\text{Suc}(x))})}))} \)
- \( \overline{\text{p}p} \equiv \text{Val(\lambda_T[\text{nat}]^n.(y.\text{Let (y, x.\text{Val(\text{Pred}(x))})}))} \)
- \( \overline{\text{z}z} \equiv \text{Val(\lambda_T[\text{nat}]^n.(y.\text{Let (y, x.\text{Val(\text{Zero}(x))})}))} \)
- \( \overline{\text{y}y} \equiv \text{Val(\lambda_T[\text{nat}]^n.(y.\text{Fix}_{\text{nat}}^n.(\lambda_T[\sigma]^n.(x.\text{Let (y, f, f(x))}))}}} \)
- \( \overline{\text{m}m} \equiv \text{Let (\overline{\text{m}}, \overline{f}^{\overline{\text{m}}^n}))} \)
- \( \overline{\lambda x : \sigma.m} \equiv \text{Val(\lambda_T[\sigma]^n.(x.\overline{\text{m}}^n))} \)
Note that this interpretation is one of a number of possibilities. Of course, for most of the syntax of HPCF there will only be one sensible translation. However, in the case of the fixpoint constants $Y_{\sigma}$, there are two reasonable translations and (as we shall see) they have quite different properties. This said, the important requirement of any translation is that it preserves the structure and properties of the original language. In Section 6.8 we shall give an alternative translation of $Y_{\sigma}$ and investigate its properties.

Interpretation of the Dynamic Semantics

This is the same as for QL: see Page 103

6.7 Adequacy Results for HPCF

Static Adequacy for HPCF

We prove the following Proposition, establishing that the translation of the static semantics of HPCF is, in a sense to be made precise, information preserving.

**Proposition 6.7.1** ["HPCF Static Adequacy"] The interpretation of the static semantics of HPCF in FIX is adequate, in the sense that $x_i: \sigma_i \vdash m: \sigma$ is a well formed HPCF expression in context iff

$$x_i: T[\sigma_i]^n \vdash \bar{u}.[m]^n(\bar{x}): T[\sigma]^n$$

is derivable in FIX.

**Proof** The forwards direction is an induction on the structure of the term $m$; we illustrate one case.

(Case $m$ is $Y_{\sigma}m$): By induction and the definition of the translation, we have

$$x_i: T[\sigma_i]^n \vdash \bar{u}.[m]^n(\bar{x}): T[\sigma]^n \to T[\sigma]^n$$

and thus (using the fact that the raw terms (represented by) $\bar{u}.[m]^n(\bar{x})$ and $[m]^n[\bar{x}/\bar{u}]$ are the same)

$$x_i: T[\sigma_i]^n \vdash \text{Let} ([m]^n, x.\text{Fix}(x)): T[\sigma]^n.$$}

From the definition of $[Y_{\sigma}m]^n$ we are done. Clearly the reverse direction is equally easy.

Dynamic Adequacy for HPCF

We shall need the following Lemma:
Lemma 6.7.2 With the call by name interpretation of HPCF, and $x: \sigma \vdash m: \tau$, $\vdash n: \sigma$ HPCF terms in context, we have

$$\vdash [m[n/x]]^n = [m]^n[[n]^n/u],$$

where $[x]^n \overset{\text{def}}{=} u$.

Proof Trivial induction. \qed

Theorem 6.7.3 ["HPCF Dynamic Adequacy"] The translation of HPCF into the FIX logic is computationally adequate; more precisely, given closed HPCF terms $m$ and $c$ where $c$ is canonical, then $m \Rightarrow c$ implies $\vdash [m]^n = [c]^n$ and if $\vdash [m]^n = [c]^n$ then there is a canonical $c'$ for which $m \Rightarrow c'$.

Proof The "only if" uses rule induction on the derivation of the evaluation relation. We shall just give two cases, namely for application and fixpoint terms.

(Case Functions): Using minimality of $\Rightarrow$ and the induction hypothesis, we obtain

$$\vdash [m]^n = \text{Val}(\lambda(x.[m]^n])$$

$$\vdash [m'[n/x]]^n = [c]^n.$$ 

Hence we get

$$\vdash [mn]^n \overset{\text{def}}{=} \text{Let} ([m]^n, f.f [n]^n)$$

$$= \lambda(x.[m]^n)[n]^n$$

$$= [m']^n[[n]^n/x]$$

which via Lemma 6.7.2 = $[c]^n$

as required.

(Case Fixpoints): Using minimality of $\Rightarrow$, the induction hypothesis and the translation of application terms, we have

$$\vdash [m]^n = [Y_c]^n$$

$$\vdash \text{Let} ([n]^n, g.g [Y_c n]^n) = [c]^n.$$ 

Hence we get

$$[mn]^n = \text{Let} ([Y_c]^n, f.f [n]^n)$$

$$= \text{Fix}(\lambda(x.\text{Let} ([n]^n, f.f x)))$$

$$= \text{Let} ([n]^n, f.f [Y_c n]^n)$$

$$= [c]^n,$$

which is what we had to prove.

To prove the converse direction we could use a method similar to the one used in the proof of QL Dynamic Adequacy. The details are omitted. \qed
6.8 An Alternative Translation of Fixpoints

All of the results of Sections 6.6 and 6.7 remain true for a slightly different translation of the fixpoint constants $Y_\sigma$. However, the proof of computational adequacy of the translation is not so straightforward as before. We present a proof which uses the Existence Property of the FIX logic which was stated on Page 73.

The translation of the fixpoint constants $Y_\sigma$ now takes the form

$$\llbracket Y_\sigma \rrbracket_\mathcal{N} \overset{\text{def}}{=} \text{Val}(\lambda T[\tau_\sigma]_\mathcal{N} \rightarrow T[\tau_\sigma]_\mathcal{N})(y, \text{Let}(y, x.\text{Fix}[\tau_\sigma]_\mathcal{N}(x))).$$

In order to prove a computational adequacy result which uses this new translation, we shall need

**Lemma 6.8.1** Suppose that

$$\Gamma \vdash E : T\alpha$$
$$\Gamma, x : \alpha \vdash F(x) : T\beta$$
$$\Gamma, y : \beta \vdash \Phi(y) \text{ prop}$$

are well formed judgements in FIX. Then we have

$$\Gamma, \Lambda \vdash \diamond\langle \text{Let}(E, F), \Phi \rangle$$
$$\Gamma, \Lambda \vdash \diamond\langle E, x.\diamond(F(x), \Phi) \rangle$$

**Proof** The labelling of steps in the proof trees is informal and for guidance only. We have

$$\frac{(\diamond i)}{\Gamma, x : \alpha, y : \beta, \Lambda, \Phi(y), F(x) = \text{Val}(y) \vdash \diamond(F(x), \Phi)}$$

$$\frac{(\star)}{\Gamma, y : \beta, \Lambda, \diamond(E, x, \Phi(y) \& F(x) = \text{Val}(y)) \vdash \diamond(E, x.\diamond(F(x), \Phi))}$$

and

$$\frac{(\mod)(\& \text{ ad})}{\Gamma, y : \beta, \Lambda, \text{Let}(E, F) = \text{Val}(y), \Phi(y) \vdash \Phi(y) \& \diamond(E, x.F(x) = \text{Val}(y))}$$

where the step $(\star)$ follows from Lemma 4.5.2 and rule $(fr)$ is proved Proposition 4.5.3. Applying $(\text{cut})$ to the above conclusions we have

$$\Gamma, y : \beta, \Lambda, \text{Let}(E, F) = \text{Val}(y), \Phi(y) \vdash \diamond(E, x.\diamond(F(x), \Phi)).$$

Using this together with the hypothesis $\Gamma, \Lambda, \vdash \diamond(\text{Let}(E, F), \Phi)$ and $(\diamond e)$ we are done. \qed

Now we can prove computational adequacy:

112
**Theorem 6.8.2** Theorem 6.7.3 remains true if we replace the translation of the constants $Y_o$ given on Page 109 with that given on Page 112.

**Proof** Clearly the change to the original proof will only involve the fixpoint constants. Indeed, for the "only if" direction:

(Case Fixpoints): Applying minimality of $\Rightarrow$, the induction hypothesis, and the translation of application terms, we have

$$ \vdash \langle n \rangle^n = \langle Y_o \rangle^n $$
$$ \vdash \text{Let} (\langle n \rangle^n, f.\langle Y_o \rangle^n) = \langle c \rangle^n, $$

and thus

$$ \vdash \Diamond (\text{Let} (\langle n \rangle^n, f.\langle Y_o \rangle^n), x.x = [c]). $$

Applying Lemma 6.8.1 we obtain

$$ \vdash \Diamond (\langle n \rangle^n, y.\Diamond (y\langle Y_o \rangle^n), x.x = [c])). $$

Appealing to the Existence Property (Theorem 4.5.4), there is a closed term $N$ for which $\vdash \langle n \rangle^n = \text{Val}(N)$ and $\vdash \Diamond (N\langle Y_o \rangle^n, x.x = [c])$, that is $\vdash N\langle Y_o \rangle^n = \langle c \rangle^n$. Via the definition of $\langle Y_o \rangle^n$ we see that $\vdash \langle Y_o \rangle^n = \text{Fix}(N)$, yielding

$$ \vdash \langle mn \rangle^n = \text{Let} (\langle Y_o \rangle^n, f.\langle n \rangle^n) $$
$$ = \text{Let} (\langle n \rangle^n, x.\text{Fix}(x)) $$
$$ = N\text{Fix}(N) $$
$$ = \langle c \rangle^n. $$

as required. The details for the converse direction are omitted; the proof uses a technique similar to that adopted in proving QL Dynamic Adequacy.  \qed

113
Chapter 7

Representations of Scott Predomains

7.1 Scott Domains and Information Systems

It is well known that the class of Scott domains together with Scott continuous functions form a category which is equivalent to the category of information systems together with approximable maps. Note that here the Scott continuous functions are those set functions which preserve filtered colimits (i.e. directed suprema). For details see both [Sco82] and [WL83]. Of course, it is by definition that a Scott domain has a least element. We now extend Scott’s results to structures which are just like Scott domains but which do not necessarily possess a least element; we shall call these Scott predomains. The literature describes many different kinds of domain and a number of the definitions are non-standard. For this reason we elaborate on precisely what we mean by a Scott predomain.

7.2 Scott Predomains and Preinformation Systems

The Category of Scott Predomains

Definition 7.2.1 If $P$ is any poset then a subset $S$ is bounded iff $S$ is non-empty and we have $\exists p \in P . S \leq p$. We write $Bd(S)$ for this. We say that $P$ is bounded cocomplete if every bounded subset has a supremum.

An $\omega$ cocomplete partial order is a poset which possesses suprema (colimits) of $\omega$ diagrams. We refer to these as wcpos and often call $\omega$ diagrams $\omega$ chains.

A directed cocomplete partial order $D$ is a poset which has suprema of directed diagrams (recall that a directed diagram is a functor $f : F \rightarrow D$ where $F$ is a poset which is a filtered category). We refer to these as dcpo's. The image of such a directed diagram will be referred to as a directed subset of $D$. If $S$ is a directed subset of $D$ we shall write $\bigvee S$ for its supremum; we shall suppose that part of the force of this notation is that $S$ is directed. For other subsets we write $\bigvee S$ for the supremum. Finally, note that any dcpo is an $\omega$cpo.

An element $d \in D$ is finite iff $d \leq \bigvee S$ implies $\exists s \in S . d \leq s$ for all directed $S$. The set of finite elements of $D$ will be written as $D^f$. A dcpo $D$ is algebraic if for every $d$ in $D$ we have $d = \bigvee \{ e \mid e \in D^f \& e \leq d \}$; note that by definition, for any element $d$ of $D$ there is a finite element below $d$.

A Scott predomain is a bounded cocomplete algebraic dcpo. We shall say that a set function between Scott predomains which preserves suprema of directed subsets is
Scott continuous. (Note that as a functor between categories, this coincides with the categorical notion of continuity as preservation of filtered colimits).

**Proposition 7.2.2** Scott predomains and Scott continuous functions form a category, \( \text{Spd} \).

\[ \square \]

**Definition 7.2.3** Let \( C \) be a let category. Suppose that for all objects \( B \) and \( C \) the functor \( C((-) \times B, TC): C^{op} \to \text{Set} \) is represented by an object \( B \to C \). Then we shall say that \( C \) has \( T \)-exponentials.

**Proposition 7.2.4** The category \( \text{Spd} \) is a let category with respect to lifting of domains, which has (finite products), stable finite coproducts, \( \bot \)-exponentials, NNO and FPO.

**Proof** We just sketch the details. The forgetful functor \( U: \text{Spd} \to \text{Set} \) creates stable finite (co)products in \( \text{Spd} \). Given a Scott predomain \( D \) we define the lifted Scott predomain \( D_\bot \) as expected. There is an obvious inclusion \( i: D \to D_\bot \) and for a Scott continuous function \( f: D \times D' \to D''_\bot \) there is \( f^*: D \times D'_\bot \to D''_\bot \) sending \((d, \bot)\) to \( \bot \). It is easy to see that this gives rise to a let category. Now we show that \( \text{Spd}((-) \times B, C_\bot) \) is representable, say by a Scott predomain \( B \to C \). We define the underlying set of \( B \to C \) to be the set of Scott continuous functions from \( B \) to \( C_\bot \) which is a poset ordered pointwise. \( B \to C \) is a dcpo: For let \( F \subseteq B \to C \) be a directed subset. Then setting \((\bigvee F)(b) \overset{\text{def}}{=} \bigvee Fb \) yields the supremum of \( F \). Now let \( F \) be non-empty and bounded by \( f \). Then we have \( Fb \leq fb \) for any \( b \in B \); as \( C_\bot \) is bounded cocomplete \( \bigvee Fb \) exists in \( C_\bot \) and hence we have \( \bigvee F \) in \( B \to C \).

Finally we have to show that \( B \to C \) is algebraic. Consider the set function defined by

\[
[b, c](x) \overset{\text{def}}{=} \begin{cases} c & \text{if } b \leq x \\ \bot & \text{otherwise} \end{cases}
\]

where \( b \in B^o, c \in C^o \) and \( x \in B \). Then it is easy to check that every \([b, c]\) is Scott continuous and finite; indeed all finite elements of \( B \to C \) arise in this way and it is the case that if \( f \in B \to C \) then \( f = \bigvee \{[b, c] \mid [b, c] \leq f \} \). We omit details: the essence of the proof can be found in [Sco71]. Recall that the category \( C \) of dcpo's and Scott continuous functions is a ccc. Of course \( \text{Spd} \) is a full subcategory of \( C \) and thus the natural isomorphism

\[
\text{Spd}((-) \times B, C_\bot) \cong \text{Spd}((-), B \to C)
\]

is immediate. Finally, the expected candidates for the NNO and FPO are easily seen to work. \[ \square \]

**Remark 7.2.5** Note that the category \( \text{Spd} \) is not cartesian closed. For more details about cartesian closure of categories of domains see [Jun88].
The Category of Preinformation Systems

Information systems provide a form of representation theorem for Scott domains. In essence, every such domain corresponds in a natural way to a set of sets which is ordered by inclusion. We shall describe a version of the original information systems from which we may derive a similar representation theorem for Scott predomains.

Definition 7.2.6 The category of preinformation systems, $\mathcal{P}ILnS$ consists of objects $A \overset{\text{def}}{=} (A, \downarrow, \vdash)$ triples which are either $(\emptyset, \emptyset, \emptyset)$, or else $A$ is a nonempty set, $\downarrow$ is a nonempty set of finite subsets of $A$, and $\vdash$ is a subset of $\downarrow \times A$. The three co-ordinates of the triple are respectively known as the tokens, the consistent sets and the the entailment relation. Note that we shall confuse the preinformation system $A$ with the token set $A$. These triples satisfy the following data:

1. $\emptyset \notin \downarrow$.
2. $X \subset' Y \vdash \iff X \vdash$, where $\subset'$ denotes non-empty finite subset and $X \vdash$ means $X \in \downarrow$.
3. $a \in A \vdash \iff \{a\} \vdash$.
4. $X \vdash a \iff X \cup \{a\} \vdash$.
5. $X \vdash a \& a \in X \vdash \iff X \vdash a$.
6. $X \vdash Y \vdash \iff X \vdash a$ where $X \vdash Y$ means $X \vdash y$ for each $y \in Y$.

Note that part of the force of the judgement $X \vdash a$ is that $X$ is consistent. We refer to the objects as preinformation systems and $(\emptyset, \emptyset, \emptyset)$ as the empty preinformation system.

The morphism sets $\mathcal{P}ILnS(A, B)$ are empty if $B = \emptyset$ and $A \neq \emptyset$, $\{\emptyset\}$ if $A = \emptyset$ and otherwise consist of all those $r \subset \downarrow_A \times \downarrow_B$ which satisfy

1. $\forall a \in A. \exists Y \downarrow_B. \{a\} r Y$.
2. $X r Y \& X r Y' \iff X r (Y \cup Y')$.
3. $X' \vdash_A X r Y \vdash_B Y' \iff X' r Y'$.

We refer to a morphism $r: A \rightarrow B$ as a preapproximable map; the identity on $A$ is just $\vdash_A$ and composition is the usual composition of relations.

Remark 7.2.7 This definition is clearly very similar to that of an information system as given in [Sco82] and [WL83]. In Scott's original paper, the token sets contain a distinguished element $\Delta$ which plays the role of a least element in the corresponding domain. However, if this requirement is removed, the resulting information systems still represent Scott domains as is noted in [WL83]; the (consistent) empty set plays the role of a bottom element. Thus in [WL83] there are simply
more information systems in any equivalence class which represents a particular domain than is the case in Scott's paper [Sco82]. However, if the requirement that the empty set be consistent is removed, then the resulting structures will, as we shall see, represent Scott predomains.

However, if this step is taken, the original definition of approximable map must be altered in order that the category of preinformation systems be equivalent to that of Scott predomains. Condition (1) imposes a direct "total functionality" condition on the preapproximable maps. If the definition of approximable map is inspected, where say \( r: A \to B \) is an approximable map, then for any \( \{a\} \in A \) there may not be \( Y \downarrow B \) for which \( \{a\}rY \). If this is the case, then the continuous function \( \mid r \mid \) between domains \( \mid A \mid \) and \( \mid B \mid \) corresponding to \( r: A \to B \) would map \( a \) to \( \bot \). Working with Scott predomains means that there may not be a least element to absorb this inherent partiality in the definition of approximable map.

**Proposition 7.2.8** Definition 7.2.6 does indeed yield a category \( p\mathcal{I}nS \).

**Proof** This is essentially routine. We just look at condition (1) for the composition \( A \Rightarrow B \Rightarrow C \) between non-empty preinformation systems. Let \( a \in A \). As \( r \) and \( s \) are preapproximable maps there is \( Y \downarrow B \) such that \( \{a\}rY \) and \( \forall y \in Y, \exists Z_y \downarrow C \cdot \{a\}rY \vdash B \{y\}sZ_y \), hence \( \{a\}rYsZ_y \). But \( Y \) is finite and thus \( Ys \cup \{Z_y \mid y \in Y\} \) implying \( \{a\}s \cup \{Z_y \mid y \in Y\} \). The details of conditions (2) and (3) for preapproximable maps are essentially as in [Sco82]. □

### 7.3 Equivalence of the Categories \( p\mathcal{I}nS \) and \( Spd \)

**Scott Families**

Our aim now is to prove that the categories \( p\mathcal{I}nS \) and \( Spd \) are equivalent. In order to do this we introduce the auxiliary notion of Scott family of sets.

**Definition 7.3.1** A **Scott family** of sets is a set of non-empty sets \( \mathcal{F} \) where

1. For directed \( S \subseteq \mathcal{F} \) we have \( \bigcup^\theta S \in \mathcal{F} \).
2. For non-empty \( U \subseteq \mathcal{F} \) we have \( \bigcap U \in \mathcal{F} \) whenever \( \bigcap U \) is non-empty.

**Remark 7.3.2** We shall often refer to Scott predomains as **domains**, Scott continuous functions as **continuous functions** and preinformation systems as **presystems**.

**Proposition 7.3.3** There is a functor \( \mid - \mid : p\mathcal{I}nS \to Spd \) given by the following prescription:

On objects, \( \mid A \mid \) is the empty domain when \( A \) is the empty presystem and otherwise consists of the non-empty subsets \( U \subseteq A \) such that

(i) \( X \subseteq \downarrow U \) implies \( X \downarrow \).
(ii) \( X \subset^f U \& X \vdash a \) implies \( a \in U \).

On morphisms, \( |r| : |A| \to |B| \) is given by

\[
|r|(U) \overset{\text{def}}{=} \{ b \in B \mid \exists X \subset^f U. X \vdash r\{b\} \}\.
\]

We shall refer to an element \( U \) of \( |A| \) as a point of \( A \).

**Proof** The following Lemma will prove useful:

**Lemma 7.3.4** Let \( (A, \sqcup, \vdash) \) be a non-empty presystem, \( X \sqcup \) and \( Y \subset^f A \). Then

(i) \( X \vdash Y \) implies \( X \sqcup Y \sqcup \) and \( Y \sqcup \).

(ii) If \( X \sqcup \) then \( \overline{X} \overset{\text{def}}{=} \{ a \mid X \vdash a \} \) is a point of \( A \).

**Proof** (i) is a simple induction on the cardinality of the (finite) set \( Y \). (ii) is a consequence of (i). \( \square \)

We have to show that \( |A| \) is a domain; this has only to be checked when \( A \) is non-empty. First we prove that \( |A| \) is a Scott family of sets and then show every such family is a domain.

By construction \( |A| \) is a set of non-empty sets. We check it is a Scott family:

1. Take \( S \subset |A| \) directed. Certainly \( \bigcup^\emptyset S \) is a non-empty subset of \( A \). (i) Let \( X \subset^f \bigcup^\emptyset S \). \( X \) is finite so \( X \subset^f S \in S \) and thus \( X \sqcup \). (ii) Let \( X \vdash a \); then \( a \in S \subset \bigcup^\emptyset S \).

2. Take non-empty \( U \subset |A| \) for which \( \bigcap U \neq \emptyset \). By hypothesis there is \( U \in \mathcal{U} \):

   (i) \( X \subset^f \bigcap U \subset U \) implies \( X \sqcup \). (ii) If also \( X \vdash a \) then \( a \in U \) for any such \( U \), i.e. \( a \in \bigcap \mathcal{U} \).

Obviously \( |A| \) has a poset structure when ordered by inclusion; that it is a Scott family says immediately it is a dcpo.

\( |A| \) is bounded cocomplete: Take \( \mathcal{U} \subset |A| \) bounded, say by \( U' \in |A| \) and set \( V \overset{\text{def}}{=} \{ V \in |A| \mid \mathcal{U} \subset V \} \); as \( U' \in \mathcal{V} \), \( \mathcal{V} \) is itself non-empty. By hypothesis there is a non-empty set \( U \in \mathcal{U} \); then any element \( u \in U \) will be an element of every \( V \in \mathcal{V} \) and hence \( \bigcap \mathcal{V} \) is non-empty. As \( |A| \) is a Scott family, this means \( \bigcup \mathcal{U} = \bigcap \mathcal{V} \in |A| \) and this is certainly the supremum of \( \mathcal{U} \).

Finally, we show that the dcpo \( |A| \) is algebraic: It will be convenient to have the

**Lemma 7.3.5** The finite elements of the dcpo \( |A| \) are given by the collection \( \{ \overline{X} \mid X \sqcup \} \).

**Proof** *(Suppose \( U \in |A| \) is finite):* Clearly \( U = \bigcup^\emptyset (\overline{X} \mid X \subset^f U) \); this makes sense, for any such \( X \) is consistent in \( A \). As \( U \) finite, \( U \subset \overline{X_0} \) for some \( X_0 \subset^f U \). As \( U \) is entailment closed, we have also \( \overline{X_0} \subset U \), as desired.

*(Suppose \( \overline{X} \in |A| \) for \( X \sqcup \)*): Let \( \overline{X} \subset \bigcup^\emptyset S \). \( X \) is of finite cardinality and so \( X \subset S \) for some \( S \in S \). By entailment closure \( \overline{X} \subset S \in |A| \) showing \( \overline{X} \) is finite. \( \square \)
Let $U \in |A|$. Then certainly we have $U = \bigcup^0 \{X \mid X \subset I \ U\}$ and it is easy to see using Lemma 7.3.5 that the directed set consists precisely of the finite elements below $U$ i.e. $|A|$ is algebraic.

Thus we have shown that $|A|$ is a domain; it remains to demonstrate that $|-|$ is well defined and functorial on morphisms.

Let $r : A \to B$ be a preapproximable map. Then $|r|$ is well defined: Take $U \in |A|$ and we show $|r|(U) \in |B|$. Let $Y \subset I \ |r|(U)$. Then for any $y \in Y$ we have $\exists X_y \subset I \ U.X_y r\{y\}$ and it follows from the properties enjoyed by $U$ and $r$ that $\bigcup \{X_y \mid y \in Y\} \vdash_A X_y r\{y\} \vdash_B \{y\}$ implying $\bigcup \{X_y \mid y \in Y\} r\{y\}$. But $y$ is arbitrary in the finite set $Y$ giving $\bigcup \{X_y \mid y \in Y\} rY$ and so $Y \downarrow_B$. If also $Y \vdash_B b$ then it is immediate that $\bigcup \{X_y \mid y \in Y\} r\{b\}$ and we are done.

$|r|$ is a continuous function: To see this take $\{U_i \mid i \in I\} \subset |A|$ directed. It is easy to see that $\{r|(U_i) \mid i \in I\}$ is directed and hence $\bigcup^0 \{r|(U_i) \mid i \in I\}$ exists in $|B|$. Certainly $\bigcup^0 \{r|(U_i) \mid i \in I\} \subset |r|(\bigcup^0 \{U_i \mid i \in I\})$. For the converse take $b \in |r|(\bigcup^0 \{U_i \mid i \in I\})$ and so $\exists X \subset I \bigcup^0 \{U_i \mid i \in I\}.X r\{b\}$. But $X$ is finite and so $X \subset I \ U_{i_0}$ i.e. $b \in |r|(U_{i_0}) \subset \bigcup^0 \{r|(U_i) \mid i \in I\}$.

$|-|$ is functorial on morphisms: $|-| = id_{|A|}$ for any $U \in |A|$ is entailment closed. Now take $A \preceq B \preceq C$ between non-empty presystems and let $U \in |A|$; we omit to check the degenerate cases involving empty presystems. We have

$$|sr|(U) = \{c \mid \exists X \subset I \ U.\exists Y \downarrow_B.X rY \& Y s\{c\}\}$$

and

$$|s||r|(U) = \{c \mid \exists Y \subset I \ b \mid \exists X \subset I \ U.X r\{b\}.Y s\{c\}\}.$$ 

Take $c \in |s||r|(U)$ so that $\forall y \in Y.\exists X_y \subset I \ U.X_y r\{y\}$ where $Y s\{c\}$. $Y$ is finite and so we have $\bigcup \{X_y \mid y \in Y\} \vdash_A X_y r\{y\}$ leading to $\bigcup \{X_y \mid y \in Y\} r\{y\}$ and thus $\bigcup \{X_y \mid y \in Y\} rY$. Thus $c \in |sr|(U)$. The reverse inclusion is trivial and so we may deduce from this that $|sr| = |s||r|$. This completes the proof of Proposition 7.3.3.

Now we show that there is a functorial construction of presystems from domains. More precisely we have the

**Proposition 7.3.6** There is a functor $\Xi : Spd \to p\mathcal{I}nS$ given by the following prescription:

On objects define $\Xi D$ to be the empty presystem if $D$ is empty and otherwise $\Xi D \overset{def}{=} (D^0, \vdash, \downarrow)$ where

1. $D^0$ is the set of finite elements of $D$.
2. $X \downarrow$ iff $X \subset I \ D^0 \& Bd(X)$.
3. $X \vdash d$ iff $X \downarrow \& d \leq \forall X \& d \in D^0$.

On morphisms, $\Xi f : \Xi D \to \Xi E$ is specified by the relation $\Xi f \subset \downarrow_{\Xi D} \times \downarrow_{\Xi E}$ given by

$$X \Xi f Y \text{ iff } \forall Y \leq f(\forall X).$$

122
Proof We have to show that $\Xi D$ is a presystem; we just sketch the details when $D$ is non-empty. $D$ is algebraic so there must be at least one finite element, implying $\emptyset \neq \bot \in P_{\text{fin}}(D^\circ)$. We have $\bot \in \bot \times D^\circ$ by definition. The conditions (1) to (6) of Definition 7.2.6 are easy to verify. For (1) the empty set is not consistent for it is not bounded. For (6) suppose that $X \vdash Y \vdash d$; it is immediate that $d \leq \bigvee Y \leq \bigvee X$, i.e. $X \vdash d$.

Now we need to see that $\Xi$ is well defined and functorial on continuous functions; we just sketch the former. Take $f : D \rightarrow E$ a continuous function between non-empty domains. We look at condition (1) of Definition 7.2.6. Let $d \in \Xi D$ and so by algebraicity of $E$ there is a finite $e \in E$ with $e \leq f(d)$. Thus $\{d\} \Xi f\{e\}$; conditions (2) and (3) are equally trivial. Confirming functoriality on continuous functions is a routine calculation. \qed

Proof of the Equivalence

With the machinery just set up we can now prove the next theorem:

Theorem 7.3.7 The functors $\dashv - : p\mathcal{I}n\mathcal{S} \rightarrow \mathcal{Spd}$ and $\Xi : \mathcal{Spd} \rightarrow p\mathcal{I}n\mathcal{S}$ give rise to an equivalence of categories.

Proof Let $D$ be a domain and $A$ a presystem. It will be convenient to write $\Xi D \overset{\text{def}}{=} (D^\circ, \bot, \vdash)$. Of course we simply check that we have an isomorphism which is natural on components $D$ and $A$; we consider $D$ first.

There is an isomorphism natural in $D$, $\theta : D \cong [\Xi D] : \phi$, given by

$$\theta(d) \overset{\text{def}}{=} \{e \in D^\circ \mid e \leq d\}$$

and $\phi(U) \overset{\text{def}}{=} \bigvee^\theta U,$

on non-empty $D$ and by the empty continuous function when $D = \emptyset$.

$\theta$ is well defined: $U \overset{\text{def}}{=} \{e \in D^\circ \mid e \leq d\}$ is a directed hence non-empty subset of $D^\circ$. To see that $U \in [\Xi D]$ let $X \subset^\bot U$. Then

1. $X$ is bounded by $d$ so $X \bot$.

2. If $X \vdash e$ then $e \leq \bigvee X \leq \bigvee^\theta U = d$ and so $e \in U$.

Now for continuity: Take $S \subset D$ directed. Then $\theta(S)$ is certainly directed and that $\bigcup^\theta \theta(S) = \theta(\bigvee^\theta S)$ is easy.

$\phi$ is well defined: Take $U \in [\Xi D]$; we show that $U$ is directed. $U$ is non-empty by definition and if $\{e, e'\} \subset^\bot U$ we have $\{e, e'\}$ consistent in $\Xi D$ implying $Bd(\{e, e'\})$.

Hence $s \overset{\text{def}}{=} \bigvee \{e, e'\}$ exists in $D$ and $s$ will clearly inherit finiteness from $e$ and $e'$, showing $s \in U$ on noting $\{e, e'\} \vdash s$.

$\phi$ is continuous: Take $U \subset [\Xi D]$ directed. $\phi(U)$ inherits directedness from $U$. Clearly $\phi(U) \leq \phi(\bigcup^\theta U)$ and $U \leq \bigvee^\theta \phi(U)$; this is all we need. That the pair $(\phi, \psi)$
yields an isomorphism of domains is virtually immediate; we omit the verification of naturality.

Now we write $A \overset{\text{def}}{=} (A, \downarrow, \vdash)$ and $\Xi|A| \overset{\text{def}}{=} (|A|^\circ, |A|, \vdash')$. We show that there is a natural isomorphism $r : A \simeq \Xi|A| : s$ given by the empty preapproximable map when $A$ is empty and otherwise

$$Xr\{X_i \mid i \in I\} \quad \text{iff} \quad X_i \downarrow & \& X \downarrow & \& \forall i \in I.X_i \subset X$$

$$\{X_i \mid i \in I\}sX \quad \text{iff} \quad X_i \downarrow & \& X \downarrow & \& X \subset \cup \{X_i \mid i \in I\}.$$

This definition makes sense. To see this recall Lemma 7.3.5 and also note that the supremum exists for $\{X_i \mid i \in I\} \downarrow'$ implying that $Bd(\{X_i \mid i \in I\})$ in $|A|$.

$s$ is a preapproximable map: For (1) note that $\{X\}sX$. Condition (2) is easy. For condition (3) suppose that $X' \vdash Xr\{X_i \mid i \in I\} \vdash' \{X_j \mid j \in J\}$. The only thing not clear is that for any $j$ we have $X_j \subset X'$; but it is easy to see that $X_j \subset \cup \{X_i \mid i \in I\} \subset X$ and $X \subset X'$.

Checking that $sr = \vdash$ is easy. We sketch the details for $rs = \vdash'$. Suppose that $\{X_i \mid i \in I\}rs\{X_j \mid j \in J\}$ and for some $X \downarrow$ and for each $j$ we have $X_j \subset X \subset \cup \{X_i \mid i \in I\}$ implying that $X_i \vdash \{X_j \mid j \in J\}$. Conversely suppose that $\{X_i \mid i \in I\} \vdash' \{X_j \mid j \in J\}$. We see that

$$\cup \{X_j \mid j \in J\} \subset \cup \{X_j \mid j \in J\} \subset \cup \{X_i \mid i \in I\} \in |A|$$

implying $\{X_i \mid i \in I\} \downarrow$. Finally we can conclude that $\{X_i \mid i \in I\}s \cup \{X_j \mid j \in J\}$ and $\cup \{X_i \mid i \in I\}r\{X_j \mid j \in J\}$ so we are done.

To finish, we give one case of naturality, namely given a preapproximable map $m : A \rightarrow A'$ we check that the following diagram commutes:

$$\Xi|A| \quad s \rightarrow A$$

$$\Xi|m| \quad m$$

$$\Xi|A'| \quad s \rightarrow A'$$

Suppose that $\{X_i \mid i \in I\}s\Xi|m|X'$. Then for some $\{X_j \mid j \in J\}$ we have $X' \subset \cup \{X_j \mid j \in J\} \subset |m|(|\cup \{X_i \mid i \in I\})$. Recall that $X'$ is non-empty and using the definition of $|m|$ we see that $\forall x' \in X'.\exists Y_{x'} \subset \cup \{X_i \mid i \in I\}.Y_{x'}m\{x'\}$. As $X'$ is a finite set we deduce $\cup \{Y_{x'} \mid x' \in X'\} \subset \cup \{X_i \mid i \in I\}$ and thus $\cup \{Y_{x'} \mid x' \in X'\} \vdash' \cup \{X_i \mid i \in I\}$. Collecting our conclusions together we see that $\cup \{Y_{x'} \mid x' \in X'\}mX'$ and $\{X_i \mid i \in I\}s \cup \{Y_{x'} \mid x' \in X'\}$ i.e. $\{X_i \mid i \in I\}msX'$.  

124
Conversely let \( \{X_i \mid i \in I\} \) be true. Then there is some \( X \downarrow \) for which \( \{X_i \mid i \in I\} \) and \( X \models X' \) and taking \( x' \in X' \) we have \( X \models \{x'\} \). Hence we deduce that \( \bar{X}' \supset [m](\bigcup \{X_i \mid i \in I\}) \in [a]' \) using the definition of \( [m] \) and entailment closure of points of \( [a]' \); but this says that \( \{X_i \mid i \in I\} \models [m](\bar{X}') \). Of course \( \{X'i\} \models X' \), so we are done.

\[ \Box \]

### 7.4 The Large \( \omega \text{cpo} \) of Presystems

Here we shall be a little more precise about set-theoretical conventions. Let us work with Zermelo Fraenkel (ZF) set theory and assume the existence of a universe of sets \( U \). Then a class will be a (meta)-subset of the universe \( U \). This can be made more precise by defining a class to be an equivalence class of ZF-formulae identified under universally quantified bi-implication, but we omit all formal details. We now show that the collection of all presystems forms an \( \omega \) cocomplete partially ordered class under a suitable ordering.

**Definition 7.4.1** Given presystems \( A \) and \( B \) we define an order relation \( \leq \) on the class \( PS \) of all presystems where \((\emptyset, \emptyset, \emptyset)\) is a least element and for non-empty \( A \) and \( B \), \( A \leq B \) iff

1. \( A \subset B \).
2. \( X \downarrow_A \iff X \subset A \& X \downarrow_B \).
3. \( X \models_A a \iff X \subset A \& a \in A \& X \models_B a \).

**Lemma 7.4.2** If \( A \leq B \) and the token set \( A \) equals that of \( B \) then \( A = B \).

**Theorem 7.4.3** The class \( PS \) of presystems with the above ordering is an \( \omega \) cocomplete partially ordered class with a least element.

**Proof** It is easy to see that the order \( \leq \) is indeed a partial order. Suppose that we have a chain \( \{A_i \mid i \in \omega\} \) of presystems. Then the supremum exists and is given by the presystem \( \left( \bigcup \{A_i \mid i \in \omega\}, \bigcup \{l_i \mid i \in \omega\}, \bigcup \{ \models_i \mid i \in \omega\} \right) \). The least element is the empty presystem.

**Definition 7.4.4** The category \( \omega \text{CPO} \) has objects which are \( \omega \) cocomplete partially ordered classes and morphisms which are Scott continuous function classes. Thus the category \( \omega \text{Cpo} \) is a subcategory of \( \omega \text{CPO} \).

**Proposition 7.4.5** The category \( \omega \text{CPO} \) is a full category with respect to lifting of domains which has (finite products), stable finite coproducts, \( \bot \)-exponentials, NNO and FPPO.

**Proof** The only thing in doubt is the existence of \( \bot \)-exponentials; it is possible to check that \( \omega \text{CPO} \) is closed under the formation of \( \bot \)-exponentials in the chosen formulation of set theory.

\[ \Box \]
Our aim is to see that the object $PS$ in the category $\omega CPO$ can be used to play the role of a type universe. The precise details of how this can be done will emerge in Chapter 9. Clearly the essence of the idea comes from the fact that the categories $p\mathcal{I}n\mathcal{S}$ and $Spd$ are equivalent, but as we have just seen, the class of all presystems can be seen as a (large) $\omega$cpo. We saw in Proposition 7.2.4 that $Spd$ has finite (co)products and $\bot$-exponentials. Thus so does $p\mathcal{I}n\mathcal{S}$. With a view to using $PS$ as a type universe, we give constructions of these categorical structures directly, and show that their formation is continuous with respect to the order on $PS$. We will need the following observations:

For each finite ordinal $n \in \omega$ there is a large $\omega$cpo $PS^n \overset{def}{=} PS \times \ldots \times PS$ enjoying the obvious pointwise order. Then it is easy to see that any morphism $f: PS^n \to PS$ is continuous iff it is so in each coordinate. This observation, together with the next lemma will be found useful in later work; we need the

**Definition 7.4.6** Let $f: PS \to PS$ be a function class on the the underlying class of $PS$. Then $f$ is said to be **continuous on token sets** if given a chain of presystems $\{A_n \mid n \in \omega\}$ we have $f(\bigcup \{A_n \mid n \in \omega\}) \subseteq \bigcup \{f(A_n) \mid n \in \omega\}$ where the containment is between token sets.

**Lemma 7.4.7** Let $f: PS \to PS$ be a morphism. Then $f$ is continuous iff $f$ is monotonic and continuous on tokens.

**Proof** The "only if" case is immediate. Conversely let $\{A_n \mid n \in \omega\}$ be a chain of presystems. Then $\bigcup \{f(A_n) \mid n \in \omega\} \leq f(\bigcup \{A_n \mid n \in \omega\})$ and by Lemma 7.4.2 we are done. \qed

### 7.5 Categorical Constructions in $p\mathcal{I}n\mathcal{S}$

We give explicit (canonical) constructions of finite (co)products and $\bot$-exponentials in the category $p\mathcal{I}n\mathcal{S}$. These constructions are continuous in the following sense:

**Lemma 7.5.1** There are morphisms in the category $\omega CPO$

$\text{\check{}} 0^n: 1 \to PS$

$\text{\check{}} \times^n: PS^2 \to PS$

$\text{\check{}} 1^n: 1 \to PS$

$\text{\check{}} +^n: PS^2 \to PS$

$\text{\check{}} \bot^n: PS \to PS$

$\text{\check{}} \bot^n: PS^2 \to PS$

which give rise to the canonical initial object, terminal object, liftings, binary (co)products and $\bot$-exponentials in the category $p\mathcal{I}n\mathcal{S}$.

**Proof** Throughout the proof let $A$ and $B$ be non-empty presystems; the effect of the morphisms which involve empty presystems will be clear, although we do make this explicit for the $\bot$-exponential construction. We omit all details concerning well definedness and continuity, except for $\text{\check{}} \bot^n$.

Put $\text{\check{}} 0^n(\ast) \overset{def}{=} (\emptyset, \emptyset, \emptyset)$ and $\text{\check{}} 1^n(\ast) \overset{def}{=} (\ast, \{\ast\}, \{\ast\} \vdash \ast)$; it is clear these definitions work.

Now we prescribe $\text{\check{}} \bot^n: PS \to PS$; this will take the empty presystem to the one point presystem and take $A = (A, \bot)$ to $(A, \bot, \vdash \bot)$ where

126
• $A_{\bot} \overset{\text{def}}{=} A \cup \{\bot\}$ where $\bot \not\in A$.
• $X \downarrow_{\bot}$ iff $X \setminus \{\bot\} \downarrow$ or $X = \{\bot\}$.
• $X \vdash_{\bot} a$ iff $X \setminus \{\bot\} \vdash a$ or $a = \bot$.

Given presystems $(A, \downarrow_A, \vdash_A)$ and $(B, \downarrow_B, \vdash_B)$ define $A^\times \cong B$ to be $(P, \downarrow, \vdash)$ where

• $P \overset{\text{def}}{=} A \times B$.
• $Z \downarrow$ iff $\pi_1 Z \downarrow_A \& \pi_2 Z \downarrow_B$.
• $Z \vdash p$ iff $\pi_1 Z \vdash_A \pi_1 p \& \pi_2 Z \vdash_B \pi_2 p$ where $\pi_1$ and $\pi_2$ are the projections of the product $A \times B$ in Set.

We define $A + B$ to be $(C, \downarrow, \vdash)$ where

• $C \overset{\text{def}}{=} A + B$ where we shall put $A + B \overset{\text{def}}{=} \{1\} \times A \cup \{2\} \times B$.
• $Z \downarrow$ iff $\exists X \downarrow_A. Z = \{1\} \times X$ or $\exists Y \downarrow_B. Z = \{2\} \times Y$.
• $Z \vdash c$ iff $\exists a \in A. \exists X \downarrow_A. Z = \{1\} \times X \& c = (1, a)$ \& $X \vdash_A a$ or $\exists b \in B. \exists Y \downarrow_B. Z = \{2\} \times Y \& c = (2, b) \& Y \vdash_B b$.

The morphism $\cong \rightarrow$: $PS^2 \rightarrow PS$ is defined by

$$(\langle 0, 0, 0 \rangle, \langle 0, 0, 0 \rangle) \mapsto (\{\star\}, \{\{\star\}\}, \{\star\} \vdash \star)$$
$$(A, \langle 0, 0, 0 \rangle) \mapsto (\{\{\star\}\}, \{\{\star\}\}, \{\star\} \vdash \star)$$
$$(\langle 0, 0, 0 \rangle, A) \mapsto (\{\{\star\}\}, \{\{\star\}\}, \{\star\} \vdash \star)$$
$$(A, B) \mapsto (F, \downarrow, \vdash)$$

where

• $F \overset{\text{def}}{=} \{X \supset b \mid X \downarrow_A \& b \in B\} \cup \{\star\}$.
• $Z \downarrow$ iff $Z \not\subset \mathcal{P}_{\text{fin}}(F)$ and it is either the case that $Z = \{\star\}$ or we have $Z \setminus \{\star\} \neq \emptyset \& \forall I \subset I. n. \cup \{X_i \mid i \in I\} \downarrow_A$ implies $\{b_i \mid i \in I\} \downarrow_B$ where $n = \{0, \ldots, n - 1\}$ and $Z \setminus \{\star\} = \{X_i \supset b_i \mid i \in n\}$.
• $Z \vdash f$ iff $Z \downarrow$ and either $f = \star$ or $f \neq \star$ \& $Z \setminus \{\star\} \neq \emptyset \& \cup \{b_i \mid X \vdash_A X_i\} \vdash_B b$.

First we see that $F$ really is a presystem. As $A$ and $B$ are non-empty the basic criteria of Definition 7.2.6 are satisfied. Further:

1. $\emptyset \not\subseteq \downarrow$ by definition.
2. If $Z' \subset \downarrow Z \downarrow$ then $Z' \downarrow$ is immediate.
3. Let $f \in F$. If $f = \star$ then $\{\star\} \downarrow$ by definition and if $f = X \supset b$ just note that $X \downarrow_A$ and $\{b\} \downarrow_B$.  

127
4. Let \( Z \vdash f \). If \( f = * \) then \( Z \cup \{ * \} \downarrow \) is immediate. Otherwise let \( f = X \triangleright b \) and write \( \{ X_i \triangleright b_i \mid i \in n \} \) for the non-empty set \( Z \setminus \{ * \} \). Let \( I \subset f n \). Suppose that \( \bigcup \{ X_i \mid i \in I \} \cup X \downarrow \). Using Lemma 7.3.4 we may deduce that \( \bigcup \{ X_i \mid i \in I \} \cup \{ X' \mid X \vdash A X' \} \downarrow_A \) and as \( Z \downarrow \) this means that \( \bigcup \{ b_i \mid i \in I \} \cup \{ b_j \mid X \vdash A X_j \} \downarrow_B \). Finally note that \( \bigcup \{ b_j \mid X \vdash A X_j \} \downarrow_B b \) from which we can deduce that \( \bigcup \{ b_i \mid i \in I \} \cup \{ b \} \downarrow_B \).

5. Let \( Z \downarrow \) and \( X \triangleright b \in Z \). Write \( Z \setminus \{ * \} = \{ X_i \triangleright b_i \mid i \in n \} \) where \( X_0 = X \) and \( b_0 = b \). Then it is trivial that \( \bigcup \{ b_i \mid X \vdash A X_i \} \downarrow_B b \).

6. Suppose that \( Z' \vdash Z \vdash f \). The result is trivial if \( f = * \) and so let \( f = X \triangleright b \). Checking the definitions we may safely put \( Z \setminus \{ * \} = \{ X_i \triangleright b_i \mid i \in n \} \) and deduce that \( \bigcup \{ b_i \mid X \vdash A X_i \} \downarrow_B b \) and \( \bigcup \{ b_j \mid X_i \vdash A X_j \} \downarrow_B b_i \). (Note that we have \( X \vdash X_i \) for at least one \( i \)). Obviously \( X \vdash A \bigcup \{ X_j' \mid X \vdash A X_j' \} \) and so by Lemma 7.3.4 we have \( \{ X_j' \mid X \vdash A X_j' \} \downarrow_A \). Hence \( \bigcup \{ b_j' \mid X \vdash X_j \} \downarrow_B \) and from \( \bigcup \{ b_j' \mid X_i \vdash A X_j \} \subset \bigcup \{ b_j' \mid X \vdash A X_j \} \) we can deduce that \( \bigcup \{ b_j' \mid X \vdash A X_j \} \downarrow_B b_i \). Thus \( \bigcup \{ b_j' \mid X \vdash A X_j \} \downarrow_B b \) as required.

It remains to show that \( \rightarrow^n : PS^2 \rightarrow PS \) is a morphism in \( \omega \text{CPO} \). We have only to see continuity in each coordinate, and appealing to Lemma 7.4.7 we may simply verify that \( \rightarrow^n \) is continuous on token sets in each coordinate. We verify this for the first coordinate of \( \rightarrow^n \).

Take \( A \leq A' \) and \( B \) in \( PS \). We show \( F \uparrow^n A \rightarrow^n B \leq F' \uparrow^n A' \rightarrow^n B \).

1. \( \downarrow_A \subset \downarrow_A' \) so \( F \subset F' \).

2. Note that \( Z \downarrow \) implies \( Z \subset F \). We need \( Z \downarrow \) iff \( Z \subset F \) and \( Z \downarrow' \). This is clear unless \( Z \setminus \{ * \} \) is non-empty, say \( Z \setminus \{ * \} = \{ X_i \triangleright b_i \mid i \in n \} \). Using the note we see \( \{ X_i \mid i \in I \} \downarrow \) iff \( \{ X_i \mid i \in I \} \downarrow A' \) and so \( Z \downarrow \) iff \( Z \downarrow' \).

3. We need to show that \( Z \vdash f \) iff \( Z \subset F \) & \( f \in F \) & \( Z \vdash' f \). This is only non-trivial if \( f \) is not \( * \) and \( \emptyset \neq Z \setminus \{ * \} = \{ X_i \triangleright b_i \mid i \in n \} \) with \( f = X \triangleright b \). Note that \( Z \vdash f \) implies \( Z \subset F \) and as \( X \vdash A X_i \) \( X \vdash A X_i \) we have \( Z \vdash f \) iff \( Z \vdash' f \).

Take a directed set \( \{ A_i \mid i \in I \} \) in \( PS \). We need to prove \( \bigcup \{ \forall \emptyset \{ A_i \mid i \in I \} \} \rightarrow^n B \subset \bigcup \{ F_i \mid i \in I \} \). Take \( f \in \bigcup \{ A_i \mid i \in I \} \rightarrow^n B \). Certainly we are okay if \( f \) is \( * \); let \( f = X \triangleright b \). Then \( X \downarrow \forall \emptyset \{ A_i \mid i \in I \} \), so \( X \subset A_i \) for some \( i \) and hence \( X \downarrow A_i \). Therefore \( X \triangleright b \in A_i \rightarrow^n B \subset \bigcup \{ F_i \mid i \in I \} \). \( \square \)

**Definition 7.5.2** Suppose that \( A \) and \( B \) are Scott predomains. A continuous function \( m: A \rightarrow B \) is called an embedding if there is a (necessarily unique) continuous partial function \( r: B \rightarrow A \) for which \( rm = id_A \) and \( mr \leq id_B \). \( r \) is referred to as a partial-projection. The class of Scott predomains together with embeddings (and specified partial-projections) forms a category which will be denoted by \( \text{Spd}^{sp} \). We shall write \( r(a) \downarrow \) to mean that \( r \) is defined at \( a \in A \).
Lemma 7.5.3 There is a functor \(|-|: PS \to Spd^{op}\). Moreover, the effect of \(|-|\) on objects commutes up to isomorphism (in \(Spd\)) with the functors \(\neg\neg\) and \(g\) where \(g\) runs over 0, 1, \(\bot\), \(\times\), + and \(\neg\).

Proof \(|-|\) is defined on objects by taking points. Given \(A \leq A', U \in |A|\) and \(U' \in |A'|\) we define an embedding partial-projection pair \((m, r)\) where

\[
m: |A| \xrightarrow{\sim} |A'| : r
\]

by setting

\[
m(U) \overset{\text{def}}{=} \{ a' \in A' \mid \exists X \subset U.X \vdash_A a' \},
\]

\[
r(U') \overset{\text{def}}{=} \begin{cases} A \cap U' & \text{if this is non-empty} \\ \text{undefined otherwise} & \end{cases}
\]

We omit the routine details verifying that \((m, r)\) is a well defined embedding partial-projection pair. We give the definitions of the isomorphisms and check details for \(\neg\). We begin by noting that all is clear for 0 and 1.

Define \(\vartheta : |A| \xrightarrow{\sim} \neg \neg (A) : \varphi\) by

\[
\vartheta(U) \overset{\text{def}}{=} \begin{cases} U \cup \{ \bot \} & \text{if } U \neq \bot \\ \{ \bot \} & \text{otherwise} \end{cases} \quad \varphi(V) \overset{\text{def}}{=} \begin{cases} V \setminus \{ \bot \} & \text{if } V \neq \{ \bot \} \\ \bot & \text{otherwise} \end{cases}
\]

Define \(\vartheta : |A| \times |B| \xrightarrow{\sim} |A \times \neg B| : \varphi\) by \(\vartheta(U, V) \overset{\text{def}}{=} U \times V\) and \(\varphi(W) \overset{\text{def}}{=} (\pi_1 W, \pi_2 W)\).

Define \(\vartheta : |A| + |B| \xrightarrow{\sim} |A + \neg B| : \varphi\) by

\[
\vartheta(C) \overset{\text{def}}{=} \begin{cases} \{1\} \times U & \text{if } C = (1, U) \\ \{2\} \times V & \text{if } C = (2, V) \end{cases} \quad \varphi(W) \overset{\text{def}}{=} \begin{cases} (1, \cup(Z \subset W)) & \text{where } Z = \{1\} \times Z \\ Z \cup \{Z \subset W\} & \text{where } Z = \{2\} \times Z \end{cases}
\]

where the definition of \(XZ\) and \(YZ\) and well definedness of \(\varphi\) can be seen from inspection of the construction of \(A^\neg \neg B\) in the proof of Lemma 7.5.1.

Define \(\vartheta : (|A| \rightarrow |B|) \xrightarrow{\sim} (|A| \rightarrow \neg B) : \varphi\) by

\[
\vartheta(g) \overset{\text{def}}{=} \{X \downarrow b \mid b \in g(X)\} \cup \{*\}
\]

\[
\varphi(V)(U) \overset{\text{def}}{=} \begin{cases} \{b \mid \exists X \subset U.X \downarrow b \in V\} & \text{if this is non-empty} \\ \bot & \text{else} \end{cases}
\]

(Recall that \(|A| \rightarrow |B| \overset{\text{def}}{=} |A| \rightarrow |B|_\downarrow\); see Proposition 7.2.4). \(\vartheta\) is well defined: Take \(Z \subset \vartheta(g).\) If \(Z = \{*\}\) then \(Z 1.\) Suppose not; take \(Z \setminus \{*\} \overset{\text{def}}{=} \{X_i \downarrow b_i \mid i \in \lambda\}, I \subset \lambda \) and let \(\bigcup\{X_i \mid i \in I\}\). From the definition of \(\vartheta\) and the monotonicity of \(g\) we see that

\[
\{b_i \mid i \in I\} \subset \bigcup \{g(X_i) \mid i \in I\} \subset g(\bigcup \{X_i \mid i \in I\}) \in |B|_\downarrow.
\]
Thus $Z \Downarrow$ as required. Now suppose also that $Z \vdash f$. If $f = *$ then $f \in \vartheta(g)$. Suppose not. We have $\bigcup \{ b_i \mid X_i \models b \} \vdash Bb$ where $f = X \triangleright b$ and so $X \models X_i$ for at least one $i$: let $I$ index such $X_i$. Note that $X \vdash \bigcup \{ X_i \mid i \in I \} \models A$. Of course $\bigcup \{ X_i \mid i \in I \} \subseteq \overline{X}$ and arguing as above we conclude $\{ b_i \mid i \in I \} \subseteq g(\overline{X}) \subseteq |B| \Downarrow$ implying that $b \in g(\overline{X})$. Hence $f \in \vartheta(g)$.

$\varphi$ is well defined: Take $V \in |A^\triangleright \neg \neg B|$, $U \in |A|$ and show $\varphi(V)(U) \subseteq |B| \Downarrow$. For the non trivial case take $Y \models \varphi(V)(U)$ and let $y \in Y$. Then $\exists X_y \models U.y.X \triangleright y \in V$. Noting that $\bigcup \{ X_y \mid y \in Y \} \models U$ and $\{ X_y \triangleright y \mid y \in Y \} \models V$ along with the definition of $\Downarrow$ we have $\bigcup \{ y \mid y \in Y \} = Y \Downarrow_B$. Now suppose that $Y \models Bb$. Noting that $Y = \bigcup \{ y \mid \bigcup \{ X_y \mid y \in Y \} \models A \} y \models Bb$ we have $\{ X_y \triangleright y \mid y \in Y \} \models U \{ X_y \mid y \in Y \} \triangleright b$ which implies $\bigcup \{ X_y \mid y \in Y \} \triangleright b \in V$ and thus $b \in \varphi(V)(U)$. Finally we have to see that $\varphi$ is a continuous function; we omit the simple details.

$(\vartheta, \varphi)$ is an isomorphism: Suppose that $\varphi(\vartheta(g))(U)$ is not $\bot$. Then we have

$$\varphi(\vartheta(g))(U) = \{ b \mid \exists X \models U.X \triangleright b \in \{ X \triangleright b \mid b \in g(\overline{X}) \} \cup \{ * \} \}
= \{ b \mid \exists X \models U.b \in g(\overline{X}) \}
= \bigcup \vartheta(g(\overline{X})) \models X \models U \}
= g(U)$$

where the final step follows by continuity of $g$. For the converse, note that

$$\vartheta(\varphi(V)) = \{ X \triangleright b \mid \exists X' \models \overline{X}.X' \triangleright b \in V \} \cup \{ * \}.$$ 

Certainly $V \subseteq \vartheta\varphi(V)$. Now take $X \triangleright b \in \vartheta\varphi(V)$. We can find some $X'$ for which $X \models A X'$ and hence $\{ b \mid X \models A X' \} \vdash Bb$ implies $\{ X' \triangleright b \} \models \triangleright b$. Thus $X \triangleright b \in V$, completing the proof.

\[\square\]

Remark 7.5.4 Note that the construction of the product $A^\triangleright \neg \neg B$ in $pI \in S$ is quite different from the usual construction of products of information systems; for a discussion of products of information systems see [Sco82]. Note also that we have not given the full details of the categorical constructions, for example the preapproximable maps which are the projections of $|A^\triangleright \neg \neg B|$. The details are easy to fill in.

7.6 The Small $\omega$cpo of Presystems

We can avoid the set-theoretical complications of the last section by restricting the cardinality of the sets which underly our constructions.

Definition 7.6.1 A Scott predomain is countably based if its set of finite elements is countable. Such Scott predomains give rise to a full sub-category $Spd_\omega$ of $Spd$. A presystem is countably based if its token set is countable. Such presystems give rise to a full sub-category $pI \in S_\omega$ of $pI \in S$.

With this definition, it is not too difficult to verify the following results, which will be put to use in Chapter 9.
Theorem 7.6.2 The functors $|-|: \mathcal{P}nS \rightarrow \mathcal{S}pd$ and $\Xi: \mathcal{S}pd \rightarrow \mathcal{P}nS_\omega$ defined in Section 7.3 restrict to an equivalence $\mathcal{S}pd_\omega \simeq \mathcal{P}nS_\omega$. \hfill \Box

Lemma 7.6.3 The set $PS_N$ of all presystems whose token sets are subsets of $\mathbb{N}$ is an $\omega$-cpo with least element.

Proof Suprema in $PS_N$ are given by unions and the least element is the empty presystem. The details are easy to verify. \hfill \Box

Lemma 7.6.4 There are morphisms in the category $\omega\text{Cpo}$

\begin{align*}
\gamma^0:1 &\rightarrow PS_N \\
\gamma^\times: PS_N^2 &\rightarrow PS_N \\
\gamma^+: PS_N^2 &\rightarrow PS_N \\
\gamma^-: PS_N &\rightarrow PS_N
\end{align*}

which give rise to the canonical initial object, terminal object, liftings, binary (co)products and $\perp$-exponentials in the category $\mathcal{P}nS_\omega$. \hfill \Box

Lemma 7.6.5 There is a functor $|-|: PS_N \rightarrow S\text{pd}_\omega^{\text{op}}$. Moreover, the effect of $|-|$ on objects commutes up to isomorphism (in $S\text{pd}_\omega^{\text{op}}$) with the functors $\gamma g$ and $g$ where $g$ runs over $0, 1, \perp, \times, +$ and $\neg$. \hfill \Box

7.7 Some Miscellaneous Results

While it is not central to our main concerns, we note a pleasing relationship between Scott families of sets and presystems, namely that there is a one to one correspondence between them.

Definition 7.7.1 Given a Scott family of sets $\mathcal{F}$ define $A_{\mathcal{F}} = (A_{\mathcal{F}}, \perp, \top)$ to be the empty presystem if $\mathcal{F}$ is empty and otherwise put

1. $A_{\mathcal{F}} \overset{\text{def}}{=} \bigcup \mathcal{F}$.
2. $X \perp Y$ iff $X \neq \emptyset$ & $\exists U \in \mathcal{F}. X \subseteq U$.
3. $X \top a$ iff $X \perp a \in \bigcup \mathcal{F}$ & $(\forall U \in \mathcal{F}. X \subseteq U$ implies $a \in U)$.

Proposition 7.7.2 For a Scott family $\mathcal{F}$, $A_{\mathcal{F}}$ is a preinformation system. \hfill \Box

Proposition 7.7.3 Let $\mathcal{F}$ be a Scott family. Then $|A_{\mathcal{F}}| = \mathcal{F}$.

Proof We sketch the details. Showing $\mathcal{F} \subseteq |A_{\mathcal{F}}|$ is easy. To prove the converse take $U \in |A_{\mathcal{F}}|$ (we assume that $\mathcal{F}$ is non-empty). The proof goes by approximating $U$ via appropriately chosen sets; in particular that $U = \bigcup \{X \mid X \subseteq I \}$ in $\mathcal{F}$. To do this, set $V \overset{\text{def}}{=} \{V \in \mathcal{F} \mid X \subseteq I \} \in \mathcal{F}$. It is clear that $\bigcap V$ is non empty and so $X = \bigcap V \in \mathcal{F}$; hence $\{X \mid X \subseteq I \} \subseteq \mathcal{F}$. Note that this latter set is directed ({$\langle X, Y \rangle : X \subseteq U$); showing $U$ is its supremum is easy. \hfill \Box

131
Proposition 7.7.4 Let $A = (A, \downarrow, \vdash)$ be a pre-system. Then $A = A_{|A|}$.

Proof The empty case is trivial so let $A$ be non-empty. We need to show the following facts:

1. $A_{|A|} = \cup |A|$.
2. $X \downarrow_{A_{|A|}}$ iff $X \not= \emptyset \& \exists U \in |A| \cdot X \subseteq^f U$.
3. $X \vdash_{A_{|A|}}$ iff $X \downarrow_{A_{|A|}} \& a \in \cup |A| \& (\forall U \in |A| \cdot X \subseteq^f U \implies a \in U)$.

The easy details are omitted.  \hfill \Box
Chapter 8

The FIX\(\mu\) Logical System

Our goal is to define a logic in which we are able to solve recursive domain equations with the aid of the fixpoint type. The approach we adopt is to set up a logic in which there is a universal type [Car86]. The elements of this type act as codes for the external or observable types. Thus a recursive type can be realised by considering the corresponding fixpoint of the universal type. In order to make things precise, we shall define a dependently typed equational logic called FIX\(\mu\). This is essentially the same as FIX\(\lambda\) but has \(T\)-exponentials and a universal type.

8.1 The Dependently Typed Equational Logic FIX\(\mu\)

Signatures for FIX\(\mu\)

A FIX\(\mu\) signature \(S\) is specified by

- A collection of basic type valued function symbols which are tagged with an arity \(t : \text{TERM}^n \rightarrow \text{TYPE}\).
- A collection of distinguished type valued function symbols denoted by \text{unit}, \text{null}, \text{nat}, \text{fix}, \text{dom}, \text{El}.
- A collection of distinguished type valued type constructor symbols \(\times, +, -, T\).
- A collection of basic term valued function symbols which are tagged with an arity \(f : \text{TERM}^n \rightarrow \text{TERM}\).
- A collection of distinguished term valued function symbols which consists of the distinguished function symbols from a FIX\(\lambda\) signature augmented with \(\gamma\text{null}, \gamma\text{unit}, \gamma\times, \gamma+\gamma, \gamma-, \gamma T\gamma, \text{lp}, \text{jp}, \text{lc}, \text{jc}, \text{lf}, \text{jf}, \text{Ret}\).

We now define an abstract syntax signature \(\Sigma = (\text{Gar}, \text{Con})\) where we shall set \(\text{Gar} = \{\text{TYPE, TERM}\}\) and \(\text{Con}\) consists of the function symbols, type constructor symbols and a countable number of object level variables of arity \(\text{TERM}\). The distinguished symbols have the following arities:

- \text{unit, null, nat, fix, dom} : \text{TYPE}.
- \text{El} : \text{TERM} \rightarrow \text{TYPE}.
• \(\times, +, \rightarrow: \text{TYPE}^2 \rightarrow \text{TYPE}\).

• \(T: \text{TYPE} \rightarrow \text{TYPE}\).

• \(\text{null}, \unit: \text{TERM}\).

• \(\Gamma T, \text{lp, Jp, lc, Jc, lf, Jf, Ret}: \text{TERM} \rightarrow \text{TERM}\).

• \(\Gamma \times, \Gamma +, \Gamma \rightarrow: \text{TERM}^2 \rightarrow \text{TERM}\).

The raw FIX\(\mu\) types are closed expressions of the abstract syntax generated from \(\Sigma\) which have arity \(\text{TYPE}\) and the raw FIX\(\mu\) terms closed expressions with arity \(\text{TERM}\).

**Judgements in FIX\(\mu\)**

The logic FIX\(\mu\) is a dependently typed equational logic. The forms of judgement which we use involve contexts \(\Gamma\), raw terms \(M\), raw types \(\alpha\) and finite lists of raw terms \(\chi\). A context

\[\Gamma = [x_1: \alpha_1, \ldots, x_n: \alpha_n]\]

is a finite list of (variable,type) pairs where the variables are distinct and \(\text{OV}(\alpha_i) \subset \{x_1, \ldots, x_{i-1}\}\), with \(\text{OV}(\alpha)\) the finite set of object level variables in \(\alpha\). We use the notation \(\text{LEN}(L)\) to denote the length of a list \(L\). The judgements that we consider are

1. \(\Gamma\) ctx.

2. \(\Gamma \vdash \alpha\) type where \(\text{OV}(\alpha) \subset \text{OV}(\Gamma)\).

3. \(\Gamma \vdash M: \alpha\) where \(\text{OV}(M) \cup \text{OV}(\alpha) \subset \text{OV}(\Gamma)\).

4. \(\chi; \Gamma \rightarrow \Gamma'\) where \(\text{OV}(\chi) \subset \text{OV}(\Gamma)\).

5. \(\Gamma = \Gamma'\) where \(\text{LEN}(\Gamma) = \text{LEN}(\Gamma')\).

6. \(\Gamma \vdash \alpha = \alpha'\) where \(\text{OV}(\alpha) \cup \text{OV}(\alpha') \subset \text{OV}(\Gamma)\).

7. \(\Gamma \vdash M = M': \alpha\) where \(\text{OV}(M) \cup \text{OV}(M') \cup \text{OV}(\alpha) \subset \text{OV}(\Gamma)\).

8. \(\chi = \chi'; \Gamma \rightarrow \Gamma'\) where \(\text{OV}(\chi) \cup \text{OV}(\chi') \subset \text{OV}(\Gamma)\) and \(\text{LEN}(\chi) = \text{LEN}(\chi') = \text{LEN}(\Gamma)\).

**Equational theories for FIX\(\mu\)**

A FIX\(\mu\) theory \(Th\) over a signature \(Sg\) is specified by the following data:

- For each basic type valued function symbol an introductory axiom of the form \(\Gamma_t \vdash t(\vec{x})\) type.
- For each basic term valued function symbol an introductory axiom of the form $\Gamma_f \vdash f(\overline{x}) : \alpha_f$.

- A collection of judgements of the form $\Gamma \vdash M = M' : \alpha$ called the term equality axioms.

- A collection of judgements of the form $\Gamma \vdash \alpha = \alpha'$ called the type equality axioms.

The theorems of $Th$ are exactly those judgements which are provable from the following rules:

<td></td>
</tr>
</tbody>
</table>

provided $t$ has introductory axiom $\Gamma \vdash t(\overline{x})$ type and that $f$ has introductory axiom $\Gamma_f \vdash f(\overline{x}) : \alpha_f$ type.
Equational Logic: Axioms 2

\[
\begin{align*}
\Gamma \vdash M : \alpha & \quad \Gamma \vdash M' : \alpha \\
\Gamma \vdash M = M' : \alpha & \quad \Gamma \vdash \alpha = \alpha' \\
\end{align*}
\]

provided that \(\Gamma \vdash M = M' : \alpha\) is term equality axiom and that \(\Gamma \vdash \alpha = \alpha'\) is a type equality axiom.

Elementary External Types

\[
\begin{align*}
[] : \Gamma \rightarrow [] & \\
\Gamma \vdash t \text{ type} &
\end{align*}
\]

where \(t\) is one of the types \texttt{unit, null, nat, fix, dom}.

External Binary Product

\[
\begin{align*}
\Gamma \vdash \alpha \text{ type} & \quad \Gamma \vdash \beta \text{ type} \\
\Gamma \vdash \alpha \times \beta \text{ type} &
\end{align*}
\]

External Binary Coproduct

\[
\begin{align*}
\Gamma \vdash \alpha \text{ type} & \quad \Gamma \vdash \beta \text{ type} \\
\Gamma \vdash \alpha + \beta \text{ type} &
\end{align*}
\]

External T-Exponential

\[
\begin{align*}
\Gamma \vdash \alpha \text{ type} & \quad \Gamma \vdash \beta \text{ type} \\
\Gamma \vdash \alpha \rightarrow \beta \text{ type} &
\end{align*}
\]

External Computation

\[
\begin{align*}
\Gamma \vdash \alpha \text{ type} & \\
\Gamma \vdash T\alpha \text{ type} &
\end{align*}
\]

External Decoding

\[
\begin{align*}
\Gamma \vdash D : \text{dom} & \\
\Gamma \vdash \text{El}(D) \text{ type} &
\end{align*}
\]

Terms in Context
The rules for term formation in \(\text{FIX}_\alpha\) are part of \(\text{FIX}_\alpha\) with the rule for Function Terms (see Page 25) replaced by the rule for \(T\)-exponentials.
### T-Exponential Terms

\[
\begin{align*}
\Gamma, x: \alpha &\vdash F(x): T\beta & \Gamma \vdash M: \alpha \rightarrow \beta &\quad \Gamma \vdash N: \beta \\
\hline
\Gamma \vdash \lambda x(F): \alpha \rightarrow \beta & & \Gamma \vdash MN: T\beta
\end{align*}
\]

### Internal Elementary Types

\[
\begin{align*}
\Gamma \vdash \text{unit}: \text{dom} & & \Gamma \vdash \text{null}: \text{dom}
\end{align*}
\]

### Internal Binary Product

\[
\begin{align*}
\Gamma \vdash D: \text{dom} &\quad \Gamma \vdash D': \text{dom} \\
\hline
\Gamma \vdash D \times D': \text{dom}
\end{align*}
\]

### Internal Binary Coproduct

\[
\begin{align*}
\Gamma \vdash D: \text{dom} &\quad \Gamma \vdash D': \text{dom} \\
\hline
\Gamma \vdash D + D': \text{dom}
\end{align*}
\]

### Internal T-Exponential

\[
\begin{align*}
\Gamma \vdash D: \text{dom} &\quad \Gamma \vdash D': \text{dom} \\
\hline
\Gamma \vdash D \rightarrow D': \text{dom}
\end{align*}
\]

### Internal Computation

\[
\begin{align*}
\Gamma \vdash D: \text{dom} \\
\hline
\Gamma \vdash \text{T}D: \text{dom}
\end{align*}
\]

### Product Externalisation Terms

\[
\begin{align*}
\Gamma \vdash M: \text{El}(D \times D') &\quad \Gamma \vdash P: \text{El}(D) \times \text{El}(D') \\
\hline
\Gamma \vdash \text{lp}(M): \text{El}(D) \times \text{El}(D') &\quad \Gamma \vdash \text{lp}(P): \text{El}(D \times D')
\end{align*}
\]

### Coproduct Externalisation Terms

\[
\begin{align*}
\Gamma \vdash M: \text{El}(D + D') &\quad \Gamma \vdash C: \text{El}(D) + \text{El}(D') \\
\hline
\Gamma \vdash \text{lc}(M): \text{El}(D) + \text{El}(D') &\quad \Gamma \vdash \text{lc}(C): \text{El}(D + D')
\end{align*}
\]

### T-Exponential Externalisation Terms

\[
\begin{align*}
\Gamma \vdash M: \text{El}(D \rightarrow D') &\quad \Gamma \vdash F: \text{El}(D) \rightarrow \text{El}(D') \\
\hline
\Gamma \vdash \text{ff}(M): \text{El}(D) \rightarrow \text{El}(D') &\quad \Gamma \vdash \text{ff}(F): \text{El}(D \rightarrow D')
\end{align*}
\]

137
Universal Type Retraction Terms

\[ \Gamma \vdash E : T\text{dom} \quad \Gamma \vdash \text{Ret}(E) : \text{dom} \]

Computation Externalisation

\[ \Gamma \vdash D : \text{dom} \]
\[ \Gamma \vdash \text{El}(\langle T \triangleright D \rangle) = TEI(D) \]

Equations in Context
The rules for equation formation in \( \text{FIX}_m \) are part of \( \text{FIX}_m^\pi \) with the rule for Function Equations (see Page 27) replaced by the rule for \( T \)-Exponential Equations.

T-Exponential Equations

\[ \Gamma \vdash M : \alpha \to \beta \]
\[ \Gamma \vdash \lambda_\alpha(x. M x) = M : \alpha \to \beta \]
\[ \Gamma, x : \alpha \vdash F(x) : T\beta \quad \Gamma \vdash M : \alpha \]
\[ \Gamma \vdash \lambda_\alpha(F) M = F(M) : T\beta \]

Product Externalisation Equations

\[ \Gamma \vdash M : \text{El}(D^r \times D') \]
\[ \Gamma \vdash \text{lp}(\text{lp}(M)) = M : \text{El}(D^r \times D') \]
\[ \Gamma \vdash P : \text{El}(D) \times \text{El}(D') \]
\[ \Gamma \vdash \text{lp}(\text{lp}(P)) = P : \text{El}(D) \times \text{El}(D') \]

Coproduct Externalisation Equations

\[ \Gamma \vdash M : \text{El}(D^r + D') \]
\[ \Gamma \vdash \text{jc}(\text{jc}(M)) = M : \text{El}(D^r + D') \]
\[ \Gamma \vdash C : \text{El}(D) + \text{El}(D') \]
\[ \Gamma \vdash \text{jc}(\text{jc}(C)) = C : \text{El}(D) + \text{El}(D') \]

T-Exponential Externalisation Equations

\[ \Gamma \vdash M : \text{El}(D^r \to D') \]
\[ \Gamma \vdash \text{if}(M) = M : \text{El}(D^r \to D') \]
\[ \Gamma \vdash F : \text{El}(D) \to \text{El}(D') \]
\[ \Gamma \vdash \text{if}(\text{if}(F)) = F : \text{El}(D) \to \text{El}(D') \]

Universal Type Retraction Equations

\[ \Gamma \vdash D : \text{dom} \]
\[ \Gamma \vdash \text{Ret}(\text{Val}(D)) = D : \text{dom} \]

Substitution and Weakening
There are particularly useful rules concerning substitution and weakening which may be derived from the rules for deducing theorems of \( \text{FIX}_m^\pi \) theories. Indeed, we have the following lemma:
Lemma 8.1.1 The following rules are derivable, where we write $J$ for any one of the expressions $e$ type, $e = e'$, $e : e'$ or $e = e' : e''$.

\[
\begin{align*}
\chi: \Gamma \rightarrow \Gamma' \quad \Gamma \vdash J(\chi) & \quad \Gamma \vdash \alpha \text{ type} \quad \Gamma, \Gamma' \vdash J \\
\Gamma \vdash M = M': \alpha \quad \Gamma, x: \alpha, \Gamma' (x) \vdash N(x) = N'(x): \beta(x) & \\
\Gamma, \Gamma'(M) \vdash N(M) = N'(M') : \beta(M) & \\
\Gamma \vdash M = M': \alpha \quad \Gamma, x: \alpha, \Gamma' (x) \vdash \beta(x) = \beta'(x) & \\
\Gamma, \Gamma'(M) \vdash \beta(M) = \beta'(M') & 
\end{align*}
\]

Proof Proceeds by an induction on the derivation of judgements. \qed

8.2 Recursive Types via Fixpoint Objects

We have seen how to interpret types of languages as objects in categories. It is well known that the type of natural numbers can be represented as the recursive type $\mu X. X + \text{unit}$. If we are interpreting formal typing statements in, say, a category $C$, then a sensible denotation of such a recursive type would be a solution to the equation $X \cong X + 1$. More generally, recursive types can be thought of as fixpoints of assignments $A \mapsto F(A)$ on objects $A$. The type is denoted by an object $A_0$ such that $F(A_0) \cong A_0$ and the operation $F$ will usually be a functor satisfying properties which ensure that $A_0$ exists [SP82].

The basic categorical notion of a type of types in a category $C$ is that there is a category object $U$ in $C$ which is externally equivalent to $C$ indexed over itself, i.e. there is an equivalence $C(-, U) \simeq C/\cdot$. With this, an endofunctor $F$ on $C$ will give rise to an internal functor $\tilde{F}: U \rightarrow U$. Thus with the above interpretation of recursive types as a fixed point of such endofunctors $F$ we may equivalently solve for a fixed point of $\tilde{F}$. With this motivation, we prove the following proposition:

Proposition 8.2.1 There is an expression of the abstract syntax, Fix, for which given a recursive typing judgement of the form $\Gamma, x : \text{dom} \vdash D(x) : \text{dom}$ one may derive the judgements

\[\Gamma \vdash \text{Fix}(D) : \text{dom} \quad \text{and} \quad \Gamma \vdash D(\text{Fix}(D)) = D : \text{dom}.\]

Proof Set $\text{Fix} \overset{\text{def}}{=} d. \text{lt}_{\text{dom}}(y, d(\text{Ret}(y)), \sigma(\omega))$. Then the claim is immediate from the $\text{FIX}_n$ rules. \qed
Chapter 9
Categorical Semantics of the $\mathbf{FIX}_\mu$ Logic

9.1 Categories for Modelling Dependent Type Theories

We review a categorical structure which can be used to model dependent type theories. Some of the earliest work in this area was undertaken by Cartmell [Car86] with additional work by Taylor [Tay86]. Here we shall give a presentation of "categories with attributes" which is based on Pitts’ account in [Pit90a]. Further useful information can be found in [Str89], [HP89], [CGW89] and [Ben85].

Categories with Attributes

Definition 9.1.1 A category with attributes is specified by a category $\mathcal{C}$ with terminal object (called the base category) which is equipped with the following structure:

- For each object $X$ in $\mathcal{C}$, a collection of fibrations over $X$, $\text{Fib}(X)$. We write $\pi_F: X \cdot F \to X$ for the projection from the total object to the base object of $F$.

- For each morphism $f: Y \to X$ in $\mathcal{C}$ and fibration $F$ over $X$, there is a fibration $f^*F$ over $Y$ called the pullback of $F$ along $f$ for which there is a pullback square in $\mathcal{C}$ of the form

\[
\begin{array}{c}
Y \cdot f^*F \\
\downarrow \pi_{f^*F} \\
Y
\end{array}
\begin{array}{c}
f^*F \\
\downarrow \pi_F \\
X
\end{array}
\begin{array}{c}
f \\
\downarrow f \\
X
\end{array}

\]

such that we have

\[
\begin{align*}
\text{id}_X^*F &= F \\
g^*(f^*F) &= (fg)^*F \\
(f\cdot F) \circ (g\cdot f^*F) &= (fg)\cdot F
\end{align*}
\]

where $Z \xrightarrow{g} Y \xrightarrow{f} X$. 

141
Notation for Categories with Attributes

It will be convenient to adopt some notational conventions which will be useful when presenting the categorical semantics of dependent type theories.

Given a fibration \( F \in \text{Fib}(X) \) we shall write \( a \in_X F \) to indicate that \( a \) is a section of \( \pi_F \). Note that given \( f:Y \to X \) in \( \mathcal{C} \), there is a section \( f^*a \in_Y f^*F \) arising from the universal property of pullbacks.

Fibration lists \( L \) and their associated total objects \( \mathcal{L} \) are defined inductively. The empty list \([\,]\) is a fibration list with \([\,] \stackrel{\text{def}}{=} 1. If L is a fibration list and \( F \in \text{Fib}(\mathcal{L}) \), then \( L, F \) is a fibration list with \( L,F \stackrel{\text{def}}{=} \mathcal{L} \bullet F \).

Section lists \( l \) and their associated morphisms \( l \) are defined inductively. The empty list \([\,]\) is a section list \([\,]:L \to [\,] \) (where \( L \) is a fibration list) with \([\,] \stackrel{\text{def}}{=} \mathcal{L} \to 1. If l: L \to L' is a section list, \( F' \in \text{Fib}(\mathcal{L}) \) and \( a' \in_{L'} t^* F' \), then \( l, a': L \to L', F' \) is a section list with

\[
\overline{l, a'} \stackrel{\text{def}}{=} \overline{L, a'} : \overline{\mathcal{L}, t^* F'} \to \overline{\mathcal{L}, F'}. 
\]

Given a fibration list \( L, L' \) the associated projection morphism \( \pi_{L, L'}: \mathcal{L}, L' \to \mathcal{L} \) is defined by induction on the length of \( L' \). We put

\[
\pi_{[\,]} \stackrel{\text{def}}{=} \pi_{\mathcal{L}, \mathcal{L}}, \\
\pi_{L, L'} \stackrel{\text{def}}{=} \pi_{L, L'} \circ \pi_{L', F'} = \pi_{L, L'} \bullet F', \quad \pi_{L, L'} \circ \pi_{L', L'} = \pi_{L, L'} 
\]

Finally, we complete our notational conventions with the definition of generic sections. Given a fibration list \( L, F, L' \) the generic section \( \delta(L, F, L') \in \mathcal{L}_{F, L'} \pi^{*}_{F, L'} F \) is defined by appealing to the universal property of the pullback square

\[
\begin{array}{ccc}
\mathcal{L}, F, L' \bullet \pi^{*}_{F, L'} F & \overset{\pi_{F, L'} \bullet F}{\longrightarrow} & \mathcal{L} \bullet F \\
\downarrow \delta(L, F, L') & & \downarrow \pi_F \\
\mathcal{L}, F, L' & \overset{\pi_{F, L'}}{\longrightarrow} & \mathcal{L}
\end{array}
\]

together with the observation that \( \pi_{F, L'} = \pi_F \pi_{L'} \).

9.2 FIX Categories with Attributes

We have seen that the logical systems \( \text{FIX}_\pi \) and \( \text{FIX} \) correspond in a precise way to \( \text{FIX} \) categories and \( \text{FIX} \) hyperdoctrines respectively. We shall now define the categorical structure which corresponds to \( \text{FIX}_\pi \); such structures will be called \( \text{FIX} \) categories with attributes. Useful background information can be found in [Pit87] and [Joh77].

Definition 9.2.1 Let \( C \) be a category-with-attributes where for each object \( X \) of \( C \), \( \text{Fib}(X) \) is regarded as a category with objects the fibrations over \( X \) and morphisms
given by \( \text{Fib}(X)(F, F') \overset{\text{def}}{=} C/X(\pi_F, \pi_{F'}) \). Then \( C \) is a \textit{FIX category-with-attributes} if it satisfies the following conditions:

- Each \( \text{Fib}(X) \) is a let-category with (finite products), stable finite coproducts and \( T \)-exponentials. For a fibration \( F \) over \( X \) and a morphism \( f: Y \to X \) we have \( T \circ f^{-1}(F) = f^{-1}(T F) \), and the pullback functions preserve the categorical structure of the categories \( \text{Fib}(X) \).

- There are distinguished fibrations \( \hat{1}, \hat{0}, \hat{N} \) and \( \hat{U} \) over \( 1 \) such that the fibrations obtained by pulling back along the unique morphism \( !: X \to 1 \) (for any object \( X \)) are the canonical terminal object, initial object, natural numbers object and fixpoint object of the category \( \text{Fib}(X) \).

- There is a specified distinguished fibration \( \hat{U} \) over the terminal object for which \( \hat{U} \) is a retract of \( T \hat{U} \) in \( \text{Fib}(1) \). There is a specified distinguished fibration \( \tau \) over \( 1 \times \hat{U} \) which gives rise, via specified \textit{internal type constructor} morphisms

\[
\begin{align*}
\gamma^0 &: 1 \to 1 \times \hat{U} \\
\gamma^T &: 1 \times \hat{U} \to 1 \times \hat{U} \\
\gamma^+ &: 1 \times \hat{U} \to 1 \times \hat{U} \\
\gamma^n &: 1 \times \hat{U} \times 1 \times \hat{U} \to 1 \times \hat{U} \\
\gamma^- &: 1 \times \hat{U} \times 1 \times \hat{U} \to 1 \times \hat{U}
\end{align*}
\]

To certain specified canonical \textit{type decoding} isomorphisms, where we write \( \text{pr}_i: 1 \times \hat{U} \to 1 \times \hat{U} \) for projection:

1. \( \gamma^1 \overset{\cong}{\approx} \hat{1} \) in \( \text{Fib}(1) \).
2. \( \gamma^0 \overset{\cong}{\approx} \hat{0} \) in \( \text{Fib}(1) \).
3. \( \gamma^T \overset{\cong}{\approx} T \tau \) in \( \text{Fib}(1 \times \hat{U}) \).
4. \( \gamma^\times \overset{\cong}{\approx} \text{pr}_1 \times \text{pr}_2 \) in \( \text{Fib}(1 \times \hat{U} \times 1 \times \hat{U}) \).
5. \( \gamma^+ \overset{\cong}{\approx} \text{pr}_1 + \text{pr}_2 \) in \( \text{Fib}(1 \times \hat{U} \times 1 \times \hat{U}) \).
6. \( \gamma^- \overset{\cong}{\approx} \text{pr}_1 \to \text{pr}_2 \) in \( \text{Fib}(1 \times \hat{U} \times 1 \times \hat{U}) \).

The \textit{FIX Category with Attributes} \( \omega \text{Cpo} \)

The results from Chapter 7 will enable us to give a concrete example of a \textit{FIX} category with attributes. It will be convenient to have the following lemmas:

\textbf{Lemma 9.2.2} Given a continuous functor \( A: X \to \omega \text{Cpo}^{op} \) where \( X \) is an \( \omega \text{Cpo} \) and \( \omega \text{Cpo}^{op} \) is the category of embedding partial-projection pairs over \( \omega \text{Cpo} \), applying the (covariant) Grothendieck construction to \( A \) yields a morphism \( \pi_A: G(A) \to X \) in \( \omega \text{Cpo} \).

\textbf{Proof} By definition,

\[
G(A) \overset{\text{def}}{=} \Sigma_{x \in X} A_x = \{(x, U) \mid U \in A_x \land x \in X\}
\]

143
with a partial order structure given by \((x, U) \leq (x', U')\) iff \(x \leq x'\) and \(\iota_{x,x'}(U) \subset U'\) where \(\iota_{x,x'} : A_x \to A_{x'}\) is the embedding determined by the functor \(A\). We omit the details which check that \(\mathcal{G}(A)\) is an \(\omega\)cpo with the above order in which suprema of chains is given by

\[
\bigvee \{ (x_n, U_n) \mid n \in \omega \} \overset{\text{def}}{=} (\bigvee \{ x_n \mid n \in \omega \}, \bigvee \{ \iota_{x_n, \bigvee \{ x_n \mid n \in \omega \}}(U_n) \mid n \in \omega \}).
\]

It is trivial that \(\pi_A\) is continuous.

\[\square\]

**Lemma 9.2.3** Let \(I\) be a filtered category, \(C\) a cocomplete category and \(D : I \times I \to C\) a functor. Then we have

\[
\lim_{\rightarrow I \in I} \lim_{\rightarrow J \in I} D(I, J) \cong \lim_{\rightarrow J \in I} \lim_{\rightarrow I \in I} D(I, J) \cong \lim_{\rightarrow I \in I} D(I, I).
\]

**Proof** Routine application of the definition of colimit and filtered category.

\[\square\]

**Lemma 9.2.4** Let \(A : X \to \omega\text{Cpo}^{\text{op}}\) be a continuous functor. Let \(\{ x_n \mid n \in \omega \}\) be a chain in \(X\) and write \(x\) for the supremum of this chain. Then we have \(\text{id}_{A_x} = \bigvee \{ \iota_{x_n, x} r_{x_n, x} \mid n \in \omega \}\).

**Proof** This result follows from unravelling the construction of filtered colimits in the category \(\omega\text{Cpo}^{\text{op}}\). Details of a similar result for the category of embedding projection pairs over the full subcategory of \(\omega\text{Cpo}\) of pointed \(\omega\)cpos can be found in [SP82]; the proof for embedding partial-projection pairs over \(\omega\text{Cpo}\) is virtually identical.

\[\square\]

**Lemma 9.2.5** Let \(A\) and \(B\) be as in Lemma 9.2.2. Then \(f \in \omega\text{Cpo}/X(\pi_A, \pi_B)\) corresponds to an \(X\)-indexed family \(\{ f_x : A_x \to B_x \mid x \in X \}\) of continuous functions for which given \(x \leq x'\) and a chain \(\{ x_n \mid n \in \omega \}\subset X\) we have

\[
\begin{align*}
\iota_{x,x'} f_x & \leq f_{x'} \iota_{x,x'} \\
 f_x & = \bigvee \{ \iota_{x_n, x} f_{x_n} r_{x_n, x} \mid n \in \omega \} & \text{where } x & \overset{\text{def}}{=} \bigvee \{ x_n \mid n \in \omega \} \\
\end{align*}
\]

where we write \(i\) and \(j\) for embeddings, \(r\) for partial-projection. Thus for example, \(\iota_{x,x'} : A_x \to A_{x'}\).

**Proof** Note that the underlying set-theoretic function of \(f \in \omega\text{Cpo}/X(\pi_A, \pi_B)\) corresponds to a family \(\{ f_x \mid x \in X \}\) of set-theoretic functions which have the required form. It is easy to see that \(f\) is monotone just in case each \(f_x\) is monotone and 9.1 holds. Now take an arbitrary directed set in \(\mathcal{G}(A)\) of the form \(\{ (x_n, U_n) \mid n \in \omega \}\) and assume the continuity (and monotonicity) of \(f\). This leads to the requirement that

\[
\bigvee \{ \iota_{x_n, x} f_{x_n}(U_n) \mid n \in \omega \} = f_x(\bigvee \{ \iota_{x_n, x}(U_n) \mid n \in \omega \})
\]

\[\square\]
where \( x \overset{\text{def}}{=} \bigvee \{ x_n \mid n \in \omega \} \) and the set on the left hand side of equation 9.3 is a chain due to equation 9.1 (itself a consequence of the monotonicity of \( f \)). By taking an instance of equation 9.3 in which \( x_n = x_{n+1} \) for each \( n \), we see that each \( f_x \) is continuous. To see that 9.3 implies 9.2 take a chain \( \{ x_n \mid n \in \omega \} \subset X \). It is the case that \( \{ (x_n, r_{x_n,x}(U)) \mid n \in \omega \land r_{x_n,x}(U) \Downarrow \} \) is a chain in \( \mathcal{G}(A) \) where \( U \in A_x \).

We can apply an instance of equation 9.3 to this directed set and deduce:

\[
\bigvee \{ j_{x_n,x} f_{x_n}(r_{x_n,x}(U)) \mid n \in \omega \land r_{x_n,x}(U) \Downarrow \} = f_x(\bigvee \{ i_{x_n,x}(r_{x_n,x}(U)) \mid n \in \omega \land r_{x_n,x}(U) \Downarrow \})
\]

by Lemma 9.2.4 = \( f_x(U) \).

Conversely, suppose we are given a family \( \{ f_x \mid x \in X \} \) of continuous functions which satisfy 9.2. It remains to prove that the corresponding morphism \( f \) is continuous, that is 9.3 holds. Indeed we have

\[
f_x(\bigvee \{ i_{x_n,x}(U_n) \mid n \in \omega \}) = \bigvee \{ j_{x_m,x} f_{x_m} r_{x_m,x}(\bigvee \{ i_{x_n,x}(U_n) \mid n \in \omega \}) \mid m \in \omega \}
\]

= \( \bigvee \{ \bigvee \{ j_{x_m,x} f_{x_m} r_{x_m,x} i_{x_n,x}(U_n) \mid n \in \omega \} \mid m \in \omega \} \)

by Lemma 9.2.3 = \( \bigvee \{ j_{x_n,x} f_{x_n} r_{x_n,x} i_{x_n,x}(U_n) \mid n \in \omega \}
\]

= \( \bigvee \{ j_{x_n,x} f_{x_n}(U_n) \mid n \in \omega \} \).

\( \square \)

We can now prove the main result of this section, namely

**Proposition 9.2.6** The category \( \omega Cpo \) is a FIX category with attributes.

**Proof** The base category is of course \( \omega Cpo \) and this certainly has a terminal object. The collection of fibrations over a Scott predomain \( X \) is given by the collection of continuous functors of the form \( A: X \to \omega Cpo^{op} \). Recall Lemma 9.2.2: Given a fibration \( A \) over \( X \) the total object and projection are given by \( \pi_A: \mathcal{G}(A) \to X \). If \( f: Y \to X \) is a morphism in \( \omega Cpo \) we set \( f^*A \overset{\text{def}}{=} Af \). It is simple to check that

\[
\mathcal{G}(f^*A) \overset{\text{def}}{=} \Sigma_{y \in Y} Af_y \cong Y \times_X \mathcal{G}(A)
\]

and hence that we get a pullback square in \( \omega Cpo \) of the required form, where \( f \circ A: \mathcal{G}(f^*A) \to \mathcal{G}(A) \) is given by \( f \circ A(y, V) \overset{\text{def}}{=} (f(y), V) \). The functoriality conditions are satisfied, and we have shown that \( \omega Cpo \) is a category with attributes.

Now we need to see that each \( \text{Fib}(X) \) is a left category with (finite products), stable finite coproducts and \( T \)-exponentials. This structure arises pointwise. For example, given fibrations \( A \) and \( B \), their product object \( A \times B \) is defined by setting

\[
A \times B (x \leq x') \overset{\text{def}}{=} i_{x,x'} \times j_{x,x'}; A_x \times B_x \cong A_x \times B_{x'}; r_{x,x'} \times s_{x,x'}
\]

and (for example) the projection morphism on \( A \) is specified by the family of projections \( (\pi_x: A_x \times B_x \to A_x \mid x \in X) \), which are easily checked to satisfy Lemma 9.2.5.

145
We sketch the details of the set category structure, which arises by pointwise application of the properties of the set category $\omega Cpo$ (with the lifting monad): The operation on objects is given by $A \mapsto \bot A$, where $\bot A$ is defined by

$$\bot A(x \leq x') \overset{\text{def}}{=} (i_{x,x'})_\bot; (A_x)_\bot \sqsubseteq 1 (A_{x'})_\bot; (r_{x,x'})_\bot.$$ 

Morphisms $\eta_A: A \to \bot A$ are specified by the continuous family $((\eta_A)_x: A_x \to (A_x)_\bot \mid x \in X)$ with $(\eta_A)_x(U) \overset{\text{def}}{=} [U]$. Given $f: A \times B \to C$ we define $\text{lift}(f): A \times B\bot \to C\bot$ by specifying the family $\text{lift}(f)_x: A_x \times (B_x)_\bot \to (C_x)_\bot \mid x \in X)$. We omit the remaining details, but note that the structure preserving conditions are immediate.

Now we need to define the fibrations 1, $\hat{0}$, $\hat{N}$ and $\hat{\Omega}$. Let us write $\{*\}$ for the terminal object of $\omega Cpo$. Then set $\hat{1}(*) \overset{\text{def}}{=} 1, \hat{0}(*) \overset{\text{def}}{=} 0, \hat{N}(*) \overset{\text{def}}{=} N$ and $\hat{\Omega}(*) \overset{\text{def}}{=} \Omega$ where $N$ and $\Omega$ are the NNO and FPO of $\omega Cpo$. We consider the details for the FPO in Fib($X$). Thus we need to see the existence of $\omega: \hat{1} \to \bot \hat{\Omega}$ and $\sigma: \bot \hat{\Omega} \to \hat{\Omega}$ which give rise to a FPO $\hat{\Omega}$ in Fib($X$). Using Lemma 9.2.5 we need to define a family $\omega_x: \hat{1}_x \to \bot \hat{\Omega}_x \mid x \in X$ that is $\omega_x: 1 \to \Omega_\bot \mid x \in X$) and also $\sigma_x: \bot \hat{\Omega}_x \to \hat{\Omega}_x \mid x \in X$) that is $\sigma_x: \Omega_\bot \to \Omega \mid x \in X$). We take these to be the constant families given by the FPO $(\Omega, \sigma, \omega)$ of $\omega Cpo$. We omit to check the equaliser diagram requirement; however we shall give all the necessary details for the universal property of the FPO. Thus given a morphism $f: \bot A \to A$ in Fib($X$) we need a unique $h: \hat{\Omega} \to A$ for which $f \text{let}(\eta h) = h \sigma$. Using Lemma 9.2.5 this amounts to defining a unique continuous family $(h_x \mid x \in X)$ which satisfies equations 9.1 and 9.2 and for which the following diagram commutes:

$$
\begin{array}{ccc}
\Omega_\bot & \xrightarrow{\sigma} & \Omega \\
\downarrow (h_x)_\bot & & \downarrow h_x \\
(A_x)_\bot & \xrightarrow{f_x} & A_x \\
\end{array}
$$

The existence of a candidate for the family $(h_x \mid x \in X)$ is immediate from the existence of a FPO $\Omega$ in $\omega Cpo$. We need to check that the $h_x$ satisfy the conditions 9.1 and 9.2.

(Satisfaction of 9.1): Take $x \leq x'$ and consider the diagram

$$
\begin{array}{ccc}
\hat{\Omega}_x & \xrightarrow{id} & \hat{\Omega}_x' \\
\downarrow h_x & & \downarrow h_{x'} \\
A_x & \xrightarrow{j_{x,x'}} & A_{x'} \\
\end{array}
$$

together with $i_{x,x'}: (A_x)_\bot \to (A_{x'})_\bot$. Condition 9.1 demands that $j_{x,x'} h_x \leq h_{x'}id$. Indeed,

$$j_{x,x'} h_x = j_{x,x'} h_x \sigma \sigma^{-1}$$

146
(Satisfaction of 9.2): Take a chain \( \{ x_n \mid n \in \omega \} \) in \( X \) and set \( x = \bigvee \{ x_n \mid n \in \omega \} \). Put \( j_{x_n,x} : A_{x_n} \to A_x \), \( j'_{x_n,x} : (A_{x_n})_\perp \to (A_x)_\perp \) and \( r_{x_n,x} : (A_x)_\perp \to (A_{x_n})_\perp \). Then

\[
(\bigvee \{ j_{x_n,x} h_{x_n} \mid n \in \omega \})_\sigma = \bigvee \{ j_{x_n,x} h_{x_n} \sigma \mid n \in \omega \} \\
= \bigvee \{ j_{x_n,x} f_{x_n}(h_{x_n})_\perp \mid n \in \omega \} \\
= \bigvee \{ j_{x_n,x} j'_{x_n,x} r_{x_n,x} h_{x_n} \mid n \in \omega \}
\]

by Lemma 9.2.3

\[
= \bigvee \{ j_{x_n,x} f_{x_n}(h_{x_n})_\perp \mid n \in \omega \} \bigvee \{ j'_{x_n,x} r_{x_n,x} h_{x_n} \mid n \in \omega \} \\
= f_x \bigvee \{ (j_{x_n,x})_\perp h_{x_n} \perp \mid n \in \omega \} \\
= f_x \bigvee \{ (j_{x_n,x} h_{x_n})_\perp \mid n \in \omega \} \\
= f_x (\bigvee \{ j_{x_n,x} h_{x_n} \mid n \in \omega \})_\perp.
\]

Appealing to the universal property of the FPO in \( \omega \text{Cpo} \), it must be the case that \( h_x = \bigvee \{ j_{x_n,x} h_{x_n} \text{id} \mid n \in \omega \} \) which is what we wanted to prove.

We define the fibration \( \hat{U} : 1 \to \omega \text{Cpo}^{\text{op}} \) by setting \( \hat{U}(A) \overset{\text{def}}{=} PS_N \). The retract condition in \( \text{Fib}(1) \) is immediate from Lemma 7.6.3. Of course \( 1 \circ \hat{U} = 1 \times PS_N \), but we shall take this to be just \( PS_N \) in the remainder of this proof. The continuous functor \( \tau : PS_N \to \omega \text{Cpo}^{\text{op}} \) is given by using Lemma 7.6.5 and regarding \( \text{Spd}^{\text{op}} \) as a full subcategory of \( \omega \text{Cpo}^{\text{op}} \). It remains to verify the existence of certain canonical isomorphisms; we only verify \( \tau \overset{\gamma}{\to} \tau \overset{pr^{\tau}_{-}}{\to} \tau \overset{pr^{\tau}_{\perp}}{\to} \perp \) in \( \text{Fib}(PS_N \times PS_N) \) where \( pr_i : PS_N \times PS_N \to PS_N \). Unravelling the definitions, we have to see that we have a diagram of the form

\[
\Sigma_{(A,B) \in PS_N} |A^{\gamma \rightarrow B}| \cong \Sigma_{(A,B) \in PS_N} |A| \to |B|_\perp
\]

\[
\begin{array}{c}
\pi_{\gamma \rightarrow B} \\
\pi_{pr^\tau_{-} \rightarrow pr^\tau_{\perp}} \\
PS_N^2 \\
\end{array}
\]

To do this we define a family of isomorphisms in \( \omega \text{Cpo} \) which satisfy Lemma 9.2.5:

\[
(\varphi_{(A,B)} : |A^{\gamma \rightarrow B}| \cong |A| \to |B|_\perp) \quad : \quad (A,B) \in PS_N^2
\]

and to do this we use Lemma 7.6.5 (Lemma 7.5.3). We shall only check that the morphism \( \varphi_{(A,B)} \) satisfies equation 9.2. Take a chain \( \{(A_n, B_n) \mid n \in \omega \} \) in \( PS_N^2 \) and set \( (A,B) \) to be the supremum. Unravelling the details, if we write

\[
r_n : |A^{\gamma \rightarrow B}| \to |A_n^{\gamma \rightarrow B_n}| \\
s_n : |A| \to |A_n| \\
(\iota_n)_\perp : |B_n|_\perp \to |B|_\perp
\]

147
for the obvious morphisms, and set \( F_n \overset{\text{def}}{=} A_n \rightarrow\!\Rightarrow B_n \) then explicitly we have

\[
  r_n(V) \overset{\text{def}}{=} \begin{cases} 
  F_n \cap V & \text{if this is non-empty} \\
  \text{undefined otherwise} 
  \end{cases} \\
  \varphi_n(V)(U) \overset{\text{def}}{=} \begin{cases} 
  \{ b \mid \exists X \subset U. X \vdash b \in V \} & \text{if this is non-empty} \\
  \perp & \text{else} 
  \end{cases} \\
  (i_n)_{\perp} \circ f \circ s_n(U) \overset{\text{def}}{=} \begin{cases} 
  \perp & \text{if } f(A_n \cap U) \text{ is } \perp \text{ else} \\
  \{ b \mid \exists Y \subset f(A_n \cap U). Y \vdash_B b \} & \text{else} 
  \end{cases} 
\]

and we need to prove that \( \varphi = \bigvee \{ i_n \varphi_n r_n \mid n \in \omega \} \). In order to show this we introduce some notation. Put

\[
  F \overset{\text{def}}{=} A \rightarrow\!\Rightarrow B \\
  e_n \overset{\text{def}}{=} (i_n)_{\perp} \circ \varphi_n(r_n(V)) \circ s_n(U) \\
  S \overset{\text{def}}{=} \varphi(V)(U) \\
  T \overset{\text{def}}{=} \bigvee \{ e_n \mid e_n \Downarrow \}.
\]

Then we need to show that \( S = T \) where

\[
e_n = \begin{cases} 
  \text{undefined if } F_n \cap V = \emptyset \text{ or } A_n \cap U = \emptyset \text{ else} \\
  \perp & \text{if } \{ b \mid \exists X \subset A_n \cap U. X \vdash b \in F_n \cap V \} = \emptyset \text{ else} \\
  W_n \overset{\text{def}}{=} \{ b \mid \exists Y \subset f(A_n \cap U. X \vdash b \in F_n \cap V). Y \vdash_B b \}
  \end{cases}
\]

We begin by noting that \( e_n \Downarrow \) for at least one \( n \). Suppose that \( S = \perp \). Then whenever \( e_n \Downarrow \) we must have \( e_n = \perp \). Therefore \( T = \bigvee \{ \perp \mid e_n \Downarrow \} = \perp \). Now suppose that \( T = \perp \). Then whenever \( e_n \Downarrow \) there can be no \( X \subset A_n \cap U \) and \( b \in B_n \) for which \( X \vdash_B b \in F_n \cap V \). Suppose for a contradiction that \( S \) is not \( \perp \), which is to say there is \( X \subset U \) and \( b \in B \) for which \( X \vdash_B b \in V \). Then we must have \( X \vdash_B b \in F_{n_0} \) for some \( n_0 \), which implies \( X \vdash A_{n_0} \) and \( b \in B_{n_0} \). These data imply that \( e_{n_0} \Downarrow \), which is contradictory. Hence \( S = \perp \).

It follows that \( S \) is not bottom just in case \( T \) is not bottom. Thus it remains to show that \( S \) is not bottom then \( S = \bigcup \{ W_n \mid n \in \omega \} \). Let \( b \in S \). Then there is some \( X \subset A_n \) for which \( X \vdash_B b \in V \) and so \( X \vdash b \in F_{n_0} \cap V \) for some \( n_0 \). This implies \( X \vdash A_{n_0} \) and so \( X \subset A_{n_0} \cap U \). Trivially \( \{ b \} \vdash_B b \) and so \( b \in W_{n_0} \). Conversely, suppose that \( b \in W_{n_0} \) for some \( n_0 \). Then there are \( X, Y \) for which \( Y \vdash_B b \), \( X \subset A_n \cap U \), and \( X \vdash y \in F_{n_0} \cap V \) for each \( y \in Y \). Hence \( b \in B_{n_0} \) and \( \bigcup \{ y \mid X \vdash_{A_{n_0}} b \} \vdash_B b \) which implies \( \{ X \vdash y \mid y \in Y \} \vdash_{F_{n_0}} X \vdash_B b \) and hence \( X \vdash_B b \in V \). Therefore \( b \in S \).

We leave all remaining details of the type coding isomorphisms to the reader; with this, the proof is complete. \( \square \)
9.3 Categorical Semantics of $\text{FIX}_\equiv^\mu$

Structures for $\text{FIX}_\equiv^\mu$ Signatures

A \textit{structure} $\mathcal{M}$ for a $\text{FIX}_\equiv^\mu$ signature $Sg$ in $\text{FIX}$ category with attributes is specified by:

- For each basic type valued function symbol $t$, a fibration list $L_t$ and a fibration $F_t \in \text{Fib}(L_t)$.

- For each basic term valued function symbol $f$, a fibration list $L_f$, a fibration $F_f \in \text{Fib}(L_f)$ and a section $a_f \in L_f F_f$.

It is assumed that the length of the fibration lists match the arities of the function symbols.

Interpretation of $\text{FIX}_\equiv^\mu$ Expressions

Let us suppose that we have a structure $\mathcal{M}$ in a $\text{FIX}$ category with attributes $C$ for a $\text{FIX}_\equiv^\mu$ signature $Sg$. We define relations between the forms of judgement given on Page 134 and appropriate structure in $\mathcal{C}$. These relations are of the following kinds where it is assumed that the $\text{FIX}_\equiv^\mu$ judgements are well formed:

1. $[\Gamma \ \text{ctxt}] \triangleright L \text{ where } L \text{ is a fibration list with } \text{LEN}(L) = \text{LEN}(\Gamma)$. 

2. $[\Gamma \vdash \alpha \ \text{type}] \triangleright L \vdash F \text{ where } \text{LEN}(L) = \text{LEN}(\Gamma) \text{ and } F \in \text{Fib}(L)$. 

3. $[\Gamma \vdash M : \alpha] \triangleright L \vdash a : F \text{ where } \text{LEN}(L) = \text{LEN}(\Gamma), F \in \text{Fib}(L) \text{ and } a \in L F$.

4. $[\chi : \Gamma \rightarrow \Gamma'] \triangleright l : L \rightarrow L' \text{ where } \text{LEN}(L) = \text{LEN}(\Gamma) \text{ and } l : L \rightarrow L' \text{ is a section list with } \text{LEN}(l) = \text{LEN}(\chi)$.

The relations are defined inductively by the following rules:

- **Contexts**

  $\quad [\Gamma \ \text{ctxt}] \triangleright L \quad [\Gamma \vdash \alpha \ \text{type}] \triangleright L \vdash F$  

  $\quad [\Gamma, x : \alpha \ \text{ctxt}] \triangleright L, F$

- **Types**

  $\quad [\chi : \Gamma \rightarrow \Gamma'] \triangleright l : L \rightarrow L_t$

  $\quad [\Gamma \vdash t(\chi) \ \text{type}] \triangleright L \vdash L_t F_t$

- **Terms**

  $\quad \left\{ \begin{array}{l}
  [\Gamma, x : \alpha, \Gamma' \vdash \alpha \ \text{type}] \triangleright L, F, L' \vdash \pi^*_{F,L',F'}
  \\
  [\Gamma \ \text{ctxt}] \triangleright L \quad [\Gamma \vdash \alpha \ \text{type}] \triangleright L \vdash F \quad [\Gamma, x : \alpha, \Gamma \ \text{ctxt}] \triangleright L, F, L'
  \\
  [\Gamma, x : \alpha, \Gamma' \vdash x : \alpha] \triangleright L, F, L' \vdash \delta(L, F, L') : \pi^*_{F,L,F'}
  \\
  [\chi : \Gamma \rightarrow \Gamma_f] \triangleright l : L \rightarrow L_f \quad [\Gamma \vdash \alpha \ \text{type}] \triangleright L \vdash L' F_f
  \\
  [\Gamma \vdash f(\chi) : \alpha] \triangleright L \vdash L' a_f F_f
  \end{array} \right.$

149
• Term Lists

\[
\begin{align*}
\frac{[[\Gamma \text{ ctx}]()] \triangleright L}{[[\Gamma \rightarrow []()] \triangleright []() : \Gamma \rightarrow []()]} \quad \frac{[[\alpha'(\chi)]()] \triangleright L \vdash a; \Gamma' \vdash F'}{[[\chi: \Gamma \rightarrow \Gamma']()] \triangleright l: L \rightarrow L' \quad [[\Gamma' \vdash \alpha'(\chi') \triangleright \text{ type}()] \triangleright L' \vdash F']} \\
[[\chi, M: \Gamma \rightarrow \Gamma', y: \alpha'(\chi')]()] \triangleright l, a: L \rightarrow L', F'
\end{align*}
\]

• Elementary External Types

\[
\begin{align*}
\frac{[[\Gamma \rightarrow []()] \triangleright []() : \Gamma \rightarrow []()]}{[[\Gamma \rightarrow \Gamma()] \triangleright L \vdash !\ast \Omega} \\
\frac{[[\Gamma \rightarrow \Gamma()] \triangleright []() : \Gamma \rightarrow []()]}{[[\Gamma \rightarrow \Gamma()] \triangleright L \vdash !\ast \Omega} \\
\frac{[[\Gamma \rightarrow \Gamma()] \triangleright []() : \Gamma \rightarrow []()]}{[[\Gamma \rightarrow \Gamma()] \triangleright L \vdash !\ast \Omega} \\
\frac{[[\Gamma \rightarrow \Gamma()] \triangleright []() : \Gamma \rightarrow []()]}{[[\Gamma \rightarrow \Gamma()] \triangleright L \vdash !\ast \Omega}
\end{align*}
\]

where \(!: L \rightarrow 1\).

• External Binary Products

\[
\frac{[[\Gamma \vdash \alpha \text{ type}]()] \triangleright L \vdash F \quad [[\Gamma \vdash \beta \text{ type}]()] \triangleright L \vdash F'}{[[\Gamma \vdash \alpha \times \beta \text{ type}]()] \triangleright L \vdash F \times F'}
\]

• External Binary Coproducts

\[
\frac{[[\Gamma \vdash \alpha \text{ type}]()] \triangleright L \vdash F \quad [[\Gamma \vdash \beta \text{ type}]()] \triangleright L \vdash F'}{[[\Gamma \vdash \alpha + \beta \text{ type}]()] \triangleright L \vdash F + F'}
\]

• External T-Exponentials

\[
\frac{[[\Gamma \vdash \alpha \text{ type}]()] \triangleright L \vdash F \quad [[\Gamma \vdash \beta \text{ type}]()] \triangleright L \vdash F'}{[[\Gamma \vdash \alpha \rightarrow \beta \text{ type}]()] \triangleright L \vdash F \rightarrow F'}
\]

• External Computations

\[
\frac{[[\Gamma \vdash \alpha \text{ type}]()] \triangleright L \vdash F}{[[\Gamma \vdash T\alpha \text{ type}]()] \triangleright L \vdash TF}
\]

• External Decoding

\[
\frac{[[\Gamma \vdash D; dom]()] \triangleright L \vdash \langle id, d \rangle; !\ast (\hat{U})}{[[\Gamma \vdash El(D) \text{ type}]()] \triangleright L \vdash d^*\tau}
\]

where \(!: \hat{L} \rightarrow 1\) and \(d: \hat{L} \rightarrow 1 \cdot \hat{U}\).

• Unit and Null Terms

\[
\begin{align*}
\frac{[[\Gamma \text{ ctx}]()] \triangleright L}{[[\Gamma \vdash \langle \rangle; \text{ unit}]()] \triangleright L \vdash \langle id, id \rangle; 1} \quad \frac{[[\Gamma \vdash M; \alpha]()] \triangleright L \vdash a; \hat{a}}{[[\Gamma \vdash \{ \alpha(M); \alpha \} \alpha]()] \triangleright L \vdash !\alpha a; F}
\end{align*}
\]

150
where !: L → 1, v: 1 ≡ 1 • 1, κ: 1 • 0 ≡ 0 and !: 0 → L • F.

• Binary Product Terms

\[
\begin{align*}
\Gamma \vdash M: \alpha & \Rightarrow L \vdash a: F \\
\Gamma \vdash N: \beta & \Rightarrow L \vdash a': F' \\
\Gamma \vdash \langle M, N \rangle: \alpha \times \beta & \Rightarrow L \vdash \langle a, a' \rangle: F \times F' \\
\Gamma \vdash P: \alpha \times \beta & \Rightarrow L \vdash a: F \times F' \\
\Gamma \vdash \text{Fst}(P): \alpha & \Rightarrow L \vdash \pi_1 a: F \\
\Gamma \vdash \text{Snd}(P): \beta & \Rightarrow L \vdash \pi_2 a': F'
\end{align*}
\]

where \(\pi_1\) and \(\pi_2\) are the projections arising from the product \(F \times F'\) in the category \(\text{Fib}(L)\).

• Binary Copродduct Terms

\[
\begin{align*}
\Gamma \vdash M: \alpha & \Rightarrow L \vdash a: F \\
\Gamma \vdash N: \beta & \Rightarrow L \vdash a': F' \\
\Gamma \vdash \text{ln}(M): \alpha + \beta & \Rightarrow L \vdash a + a': F + F' \\
\Gamma \vdash \text{ln}(N): \alpha + \beta & \Rightarrow L \vdash a + a': F + F' \\
\Gamma, x: \alpha \vdash F(x): \gamma & \Rightarrow L, F \vdash a: \pi_1 F'' \\
\Gamma, y: \beta \vdash G(y): \gamma & \Rightarrow L, F' \vdash a': \pi_2 F'' \\
\Gamma \vdash C: \alpha + \beta & \Rightarrow L \vdash a + a': F + F' \\
\Gamma \vdash \{F, G\}(C): \gamma & \Rightarrow L \vdash [\pi_1 F'' \circ a, \pi_2 F'' \circ a'] a': F''
\end{align*}
\]

where we note that \(a: L \cdot F \rightarrow (L \cdot F) \bullet (\pi_1 F'')\), \(a': L \cdot F' \rightarrow (L \cdot F') \bullet (\pi_2 F'')\) and \([- + +]\) denotes the abstraction of unique mediating morphisms arising from the copродduct \(F + F'\) in \(\text{Fib}(L)\).

• T-Exponential Terms

\[
\begin{align*}
\Gamma \vdash F: \alpha \rightarrow \beta & \Rightarrow L \vdash a: F \rightarrow F' \\
\Gamma \vdash M: \alpha & \Rightarrow L \vdash a': F \\
\Gamma \vdash FM: T\beta & \Rightarrow ap(a, a'): TF' \\
\Gamma, x: \alpha \vdash F(x): T\beta & \Rightarrow L, F \vdash a: T\pi_1 F'' \\
\Gamma \vdash \lambda a(F): \alpha \rightarrow \beta & \Rightarrow L \vdash cur(\pi_1 T F'' \circ a \circ pr)t: F \rightarrow F''
\end{align*}
\]

where we recall that \(\pi_1 T F'' = T\pi_1 F''\) by definition and we have \(v: L \cong L \cdot *\) and \(pr: L \cdot * \times L \cdot F \rightarrow L \cdot F\).

• Computation Terms

\[
\begin{align*}
\Gamma \vdash M: \alpha & \Rightarrow L \vdash a: F \\
\Gamma \vdash \text{Val}(M): T\alpha & \Rightarrow L \vdash \eta a: TF \\
\Gamma \vdash E: T\alpha & \Rightarrow L \vdash a: TF \\
\Gamma, x: \alpha \vdash F(x): T\beta & \Rightarrow L, F \vdash a: T\pi_1 F'' \\
\Gamma \vdash \text{Let}(E, F): T\beta & \Rightarrow L \vdash let(\pi_1 T F'' \circ a') a' \circ a: TF'
\end{align*}
\]

• Natural Number Terms

\[
\begin{align*}
[()] : \Gamma \rightarrow [()] & \Rightarrow [()] : L \rightarrow [()] \\
\Gamma \vdash 0: \text{nat} & \Rightarrow L \vdash ! 0: ! \text{nat} \\
\Gamma \vdash M: \alpha & \Rightarrow L \vdash a: F \\
\Gamma, x: \alpha \vdash F(x): \alpha & \Rightarrow L, F' \vdash a': \pi_1 F" \\
\Gamma \vdash N: \text{nat} & \Rightarrow L \vdash (id, n): ! \text{nat} \\
\Gamma \vdash FN(M): \alpha & \Rightarrow L \vdash g(id, n): F
\end{align*}
\]

151
where $! : \mathcal{L} \rightarrow 1$, $0 : 1 \rightarrow 1 \bullet \hat{N}$, $s : 1 \bullet \hat{N} \rightarrow 1 \bullet \hat{N}$ and $g$ is the unique morphism arising from the universal property of the NNO $! \bullet \hat{N} \in \text{Fib}(\mathcal{L})$:

\[
\begin{array}{ccc}
\mathcal{L} \bullet ! \hat{N} & \xrightarrow{id \times 0} & \mathcal{L} \bullet ! \hat{N} \\
pr_1 & \downarrow & \downarrow g \\
\mathcal{L} \bullet F & \xrightarrow{a} & \mathcal{L} \bullet F
\end{array}
\]

- **Fixpoint Terms**

\[
\frac{[\cdot] : \Gamma \rightarrow [\cdot]}{[\cdot] : \Gamma \rightarrow [\cdot]} \quad \frac{[\cdot] \vdash T : \text{fix}}{[\cdot] \vdash \langle \text{id}, \epsilon \rangle : T ! \hat{\Omega}}
\]

\[
\frac{[\Gamma \vdash \sigma : \text{fix}}{[\Gamma \vdash \langle \text{id}, \sigma \epsilon \rangle : ! \hat{\Omega}}
\]

\[
\frac{[\Gamma \vdash N \vdash \text{fix}}{[\Gamma \vdash \langle \text{id}, n \rangle : ! \hat{\Omega}}
\]

\[
\frac{[\Gamma \vdash T \vdash F \vdash \alpha : \pi^F \pi^F]}{[\Gamma \vdash \text{let}(F, N) : \alpha] \vdash [\Gamma \vdash \langle F, N \rangle : \alpha] \vdash [\Gamma \vdash \langle \text{id}, n \rangle : F]
\]

where $! : \mathcal{L} \rightarrow 1$ and $g$ is the unique morphism arising from the universal property of the FPO $! \hat{\Omega} \in \text{Fib}(\mathcal{L})$:

\[
\begin{array}{ccc}
\mathcal{L} \bullet ! \hat{\Omega} & \xrightarrow{id \times \sigma} & \mathcal{L} \bullet ! \hat{\Omega} \\
\text{let}(\eta \gamma) & \downarrow & \downarrow g \\
\mathcal{L} \bullet TF & \xrightarrow{a} & \mathcal{L} \bullet F
\end{array}
\]

where $\eta \gamma : \mathcal{L} \bullet ! \hat{\Omega} \rightarrow \mathcal{L} \bullet F \rightarrow \mathcal{L} \bullet TF$.

- **Internal Elementary Types**

\[
\frac{[\cdot] : \Gamma \rightarrow [\cdot]}{[\cdot] : \Gamma \rightarrow [\cdot]} \quad \frac{[\cdot] \vdash \text{unit} : \text{dom}}{[\cdot] \vdash ! \sigma 0 \cdot ! \hat{U}}
\]

\[
\frac{[\cdot] \vdash \text{null} : \text{dom}}{[\cdot] \vdash ! \sigma 1 \cdot ! \hat{U}}
\]

where $! : \mathcal{L} \rightarrow 1$.

- **Internal Binary Product**

\[
\frac{[\Gamma \vdash D : \text{dom}}{[\Gamma \vdash \langle \text{id}, d \rangle : ! \hat{U}}
\]

\[
\frac{[\Gamma \vdash D' : \text{dom}}{[\Gamma \vdash \langle \text{id}, d' \rangle : ! \hat{U}}
\]

\[
\frac{[\Gamma \vdash D \times D' : \text{dom}}{[\Gamma \vdash \langle \text{id}, d \times d' \rangle : ! \hat{U}}
\]

- **Internal Binary Coproduct**

\[
\frac{[\Gamma \vdash D : \text{dom}}{[\Gamma \vdash \langle \text{id}, d \rangle : ! \hat{U}}
\]

\[
\frac{[\Gamma \vdash D' : \text{dom}}{[\Gamma \vdash \langle \text{id}, d' \rangle : ! \hat{U}}
\]

\[
\frac{[\Gamma \vdash D \vdash D' : \text{dom}}{[\Gamma \vdash \langle \text{id}, d \vdash d' \rangle : ! \hat{U}}
\]
- **Internal T-Exponential**

\[
\begin{align*}
\llbracket \Gamma \vdash D: \text{dom} \rrbracket & \Rightarrow L \vdash \langle id, d \rangle: !\hat{U} \\
\llbracket \Gamma \vdash D': \text{dom} \rrbracket & \Rightarrow L \vdash \langle id, d' \rangle: !\hat{U}
\end{align*}
\]

\[
\llbracket \Gamma \vdash D^\rightarrow \rightarrow D': \text{dom} \rrbracket \Rightarrow L \vdash \langle id, \rightarrow \rightarrow \langle d, d' \rangle \rangle: !\hat{U}
\]

- **Internal Computation**

\[
\begin{align*}
\llbracket \Gamma \vdash D: \text{dom} \rrbracket & \Rightarrow L \vdash \langle id, d \rangle: !\hat{U}
\end{align*}
\]

\[
\llbracket \Gamma \vdash \tau^T D: \text{dom} \rrbracket \Rightarrow L \vdash \langle id, \tau \rightarrow \langle d, d' \rangle \rangle: !\hat{U}
\]

- **Product Externalisation**

\[
\begin{align*}
\llbracket \Gamma \vdash M: El(D^\tau \times D') \rrbracket & \Rightarrow L \vdash a: (\tau \times \langle d, d' \rangle)^\tau \\
\llbracket \Gamma \vdash \mathfrak{p}(M): El(D) \times El(D') \rrbracket & \Rightarrow L \vdash \rho a: d^\tau \times d'^\tau \\
\llbracket \Gamma \vdash P: El(D) \times El(D') \rrbracket & \Rightarrow L \vdash a: d^\tau \times d'^\tau
\end{align*}
\]

\[
\llbracket \Gamma \vdash \mathfrak{j}(P): El(D^\tau \times D') \rrbracket \Rightarrow L \vdash \rho^{-1} a: (\tau \times \langle d, d' \rangle)^\tau
\]

where \(\rho: \mathcal{L} \bullet (\tau \times \langle d, d' \rangle)^\tau \cong \mathcal{L} \bullet (d^\tau \times d'^\tau)\).

- **Coproduct Externalisation**

\[
\begin{align*}
\llbracket \Gamma \vdash M: El(D^\tau + D') \rrbracket & \Rightarrow L \vdash a: (\tau + \langle d, d' \rangle)^\tau \\
\llbracket \Gamma \vdash \mathfrak{l}(M): El(D) + El(D') \rrbracket & \Rightarrow L \vdash \rho a: d^\tau + d'^\tau \\
\llbracket \Gamma \vdash C: El(D) + El(D') \rrbracket & \Rightarrow L \vdash a: d^\tau + d'^\tau
\end{align*}
\]

\[
\llbracket \Gamma \vdash \mathfrak{j}(C): El(D^\tau + D') \rrbracket \Rightarrow L \vdash \rho^{-1} a: (\tau + \langle d, d' \rangle)^\tau
\]

where \(\rho: \mathcal{L} \bullet (\tau + \langle d, d' \rangle)^\tau \cong \mathcal{L} \bullet (d^\tau + d'^\tau)\).

- **T-Exponential Externalisation**

\[
\begin{align*}
\llbracket \Gamma \vdash M: El(D^\rightarrow \rightarrow D') \rrbracket & \Rightarrow L \vdash a: (\rightarrow \rightarrow \langle d, d' \rangle)^\tau \\
\llbracket \Gamma \vdash \mathfrak{h}(M): El(D) \rightarrow El(D') \rrbracket & \Rightarrow L \vdash \rho a: d^\tau \rightarrow d'^\tau \\
\llbracket \Gamma \vdash F: El(D) \rightarrow El(D') \rrbracket & \Rightarrow L \vdash a: d^\tau \rightarrow d'^\tau
\end{align*}
\]

\[
\llbracket \Gamma \vdash \mathfrak{j}(F): El(D^\rightarrow \rightarrow D') \rrbracket \Rightarrow L \vdash \rho^{-1} a: (\rightarrow \rightarrow \langle d, d' \rangle)^\tau
\]

where \(\rho: \mathcal{L} \bullet (\rightarrow \rightarrow \langle d, d' \rangle)^\tau \cong \mathcal{L} \bullet (d^\tau \rightarrow d'^\tau)\).

- **Universal Type Retraction**

\[
\begin{align*}
\llbracket \Gamma \vdash E: T \text{dom} \rrbracket & \Rightarrow L \vdash \langle id, e \rangle: T! \hat{U} \\
\llbracket \Gamma \vdash \text{Ret}(E): \text{dom} \rrbracket & \Rightarrow L \vdash \langle id, \text{rete} \rangle: !\hat{U}
\end{align*}
\]

where \(\text{re}: T\hat{U} \rightarrow \hat{U}\) is the retraction morphism in \(\text{Fib}(1)\).

By inspecting the above relations we can see that they give rise to partial functions in the following way. Given a judgement \(J\) and "semantic sequents" \(S\) and \(S'\), if
If $J$ is $\llbracket J \rrbracket$ and $J' \llbracket J' \rrbracket$ then $S = S'$ in $C$. Thus if we are given a structure $Sg$ in $C$ the assignments

$$
\Gamma \mapsto \llbracket \Gamma \text{ctxt} \rrbracket
$$

$$
\Gamma, \alpha \mapsto \llbracket \Gamma \vdash \alpha \text{ type} \rrbracket
$$

$$
\Gamma, M, \alpha \mapsto \llbracket \Gamma \vdash M : \alpha \rrbracket
$$

$$
\Gamma, \chi, \Gamma' \mapsto \llbracket \chi : \Gamma \rightarrow \Gamma' \rrbracket
$$
give rise to partial functions. If one of these partial functions is defined at an argument $J$ then we write $\llbracket J \rrbracket \downarrow$.

**Models of $\text{FIX}^\mu_=$ Theories**

The notion of satisfaction of judgements arising from $\text{FIX}^\mu_=$ signatures is complicated by the type dependency. We give the definition of judgement satisfaction next, where it should be noted that in each instance of "$J$ is satisfied iff $S$" the categorical structure $S$ is unique.

1. $\Gamma \text{ctxt}$ is satisfied iff $\llbracket \Gamma \text{ctxt} \rrbracket \downarrow$.
2. $\Gamma \vdash \alpha \text{ type}$ is satisfied iff $\llbracket \Gamma \vdash \alpha \text{ type} \rrbracket \downarrow$.
3. $\Gamma \vdash M : \alpha$ is satisfied iff $\llbracket \Gamma \vdash M : \alpha \rrbracket \downarrow$.
4. $\chi : \Gamma \rightarrow \Gamma'$ is satisfied iff $\llbracket \Gamma \text{ctxt} \rrbracket \downarrow$ and $\llbracket \Gamma' \text{ctxt} \rrbracket \downarrow$.
5. $\Gamma = \Gamma'$ is satisfied iff $\llbracket \Gamma \text{ctxt} \rrbracket \Delta L$ and $\llbracket \Gamma' \text{ctxt} \rrbracket \Delta L$.
6. $\Gamma \vdash \alpha = \alpha'$ is satisfied iff $\llbracket \Gamma \vdash \alpha \text{ type} \rrbracket \Delta L \vdash F$ and $\llbracket \Gamma \vdash \alpha' \text{ type} \rrbracket \Delta L \vdash F$.
7. $\Gamma \vdash M = M' : \alpha$ is satisfied iff $\llbracket \Gamma \vdash M : \alpha \rrbracket \Delta L \vdash a : F$ and $\llbracket \Gamma \vdash M' : \alpha \rrbracket \Delta L \vdash a : F$.
8. $\chi = \chi' : \Gamma \rightarrow \Gamma'$ is satisfied iff $\llbracket \chi : \Gamma \rightarrow \Gamma' \rrbracket \Delta l : L \rightarrow L'$ and $\llbracket \chi' : \Gamma \rightarrow \Gamma' \rrbracket \Delta l : L \rightarrow L'$.

Given a $\text{FIX}^\mu_=$ theory $Th$ and a structure $M$, then we say that $M$ is a model of $Th$ if it satisfies the rules for introducing the $Th$ axioms; (these rules can be found on Page 135).

**The Substitution Lemma**

The following lemma describes how the substitution of types and terms in the syntax of a $\text{FIX}^\mu_=$ theory is modelled by the categorical structure of a $\text{FIX}$ category with attributes.

**Lemma 9.3.1** Suppose that $\llbracket \chi : \Gamma \rightarrow \Gamma' \rrbracket \Delta l : L \rightarrow L'$. Then it is the case that

- $\llbracket \Gamma' \vdash \alpha'(\vec{y}) \text{ type} \rrbracket \Delta L' \vdash F'$ implies $\llbracket \Gamma \vdash \alpha'(\chi) \text{ type} \rrbracket \Delta L \vdash \ell^* F'$. 

154
• $[[\Gamma' \vdash M'(\bar{y}): \alpha'(\bar{y})]] \Rightarrow L' \vdash a': F'$ implies $[[\Gamma \vdash M'(\chi'): \alpha'(\chi')]] \Rightarrow L \vdash \bar{a'}: \bar{F'}$.

• $[[\chi': \Gamma' \rightarrow \Gamma'']] \Rightarrow l': L' \rightarrow L''$ implies $[[\chi' \circ \chi: \Gamma \rightarrow \Gamma'']] \Rightarrow l' \circ l: L \rightarrow L''$.

**Proof** The proof proceeds by induction on the derivation of the various judgements.

---

**The Soundness Theorem**

**Theorem 9.3.2** ["FIX\(\leq\) Soundness"] Suppose we are given a FIX\(\leq\) theory \(Th\) over a FIX\(\leq\) signature \(Sg\). The collection of judgements of the theory \(Th\) which are satisfied by a structure in a FIX category with attributes \(\mathcal{C}\) is closed under the rules (see Page 135) for derivation of judgements in \(Th\). Consequently a model \(M\) of \(Th\) satisfies all the judgements which are theorems of \(Th\).

**Proof** Once again, the proof proceeds by an induction on the derivation of the various judgement forms; the previous Lemma will be used throughout the proof.
Chapter 10

Prospects for Further Research

10.1 Loose Ends and Future Tasks

We give a concise review of what has been achieved; in particular we highlight loose ends and indicate possible further lines of research. The following comments coincide roughly with the order of presentation of material in the thesis.

Modular Approaches to Program Semantics

Each of the logics $\text{FIX}_\sim$, $\text{FIX}$ and $\text{FIX}_\sim^\tau$ builds upon the computational let calculus. The fundamental notion underlying the let calculus is the separation of computations from values. The extensions we have considered provide expressive logics which allow us to reason about one particular notion of computation. The development of metalogics which combine different kinds of computation is clearly an important issue; for related work in this area see [Mog90b] and [Mog90a]. Most of the work to date concerns the combining of various monads (representing different forms of computation, such as those presented at the end of Chapter 1) at an equational level rather than at the level of predicates. The investigation of monadic predicate logics where one is able to vary the underlying monad is yet to be undertaken.

Domain Theoretic Properties of $\text{FIX}_\sim$

In a $\text{FIX}_\sim$ theory we always have fixpoints of terms at the higher order type $(\alpha \to T \beta) \to (\alpha \to T \beta)$. All concrete models presented in this thesis are domain theoretic, thus by definition objects and morphisms have an associated order. When we consider fixpoints arising from the properties of FPO's in these categories, it is always the least such which is delivered. As we saw in Chapter 3, $\text{FIX}$ categories (and hence $\text{FIX}_\sim$ theories) have properties reminiscent of concrete categories of domains and axiomatic domain theory. The precise relationship between $\text{FIX}_\sim$ and axiomatic approaches to domains needs to be established. One line of investigation is to consider what formal orders can be imposed on $\text{FIX}_\sim$ and their connection to formal fixpoints.

An example of a formal order is the following; we give the merest sketch of details. We shall need the notion of canonical and non canonical terms. These arise from the introduction and elimination rules in the $\text{FIX}_\sim$ logic. More precisely, the (raw)
canonical terms are given by the grammar
\[
C ::= \emptyset | \langle M, N \rangle | \mathsf{In}_\alpha(M) | \mathsf{In}_\alpha(F) | \mathsf{Val}(M) | \mathsf{O} | \mathsf{Suc}(N) | \omega | \sigma(E)
\]
and the non canonical terms by
\[
NC ::= \mathsf{Fst}(P) | \mathsf{Snd}(P) | \{F, G\}(C) | \mathsf{FM} | \mathsf{Let}(E, F) | \mathsf{FN}(M) | \mathsf{It}(F, N)
\]
We can define an operational reduction scheme where \( C \Rightarrow C', \mathsf{Fst}(\langle M, N \rangle) \Rightarrow M \) and so on. Write \( M[CL/\bar{x}] \) for the substitution of closed terms \( CL \) for the object level variables in \( M \) and \( \Sigma M \) for the ordered list of subterms of \( M \) (e.g. \( M \) is a subterm of \( \langle M, N \rangle \)). Then define the simulation ordering by the following fixpoint: Say that \( M \leq N \) if \( \forall CL, M[CL/\bar{x}] \Rightarrow M' \) implies \( N[CL/\bar{y}] \Rightarrow N' \) and \( \Sigma M' \leq \Sigma N' \). Some work along these lines has been carried out by Smith for the simply typed \( \lambda \) calculus augmented with surjective pairing and natural numbers. In [Smi89] Smith shows that the formal fixpoint obtained from iterating the term \( \downarrow \mathsf{def}(\lambda x.x(x))(\lambda x.x(x)) \) coincides with that arising from the usual fixpoint combinator \( Y \), where the coincidence is defined up to the equivalence generated by a simulation ordering rather like the one sketched above. However, the proof techniques are a little unwieldy. It might be possible to obtain similar results for the \( \text{FIX}_= \) logic via a logical relations argument. Using the above ordering on terms of \( \text{FIX}_= \), a partial order could be imposed on the collection of global elements of a type \( \alpha \). The definition of the category \( \mathcal{L}_r \) could be changed so that the relation \( \triangleleft \) of an object \( (D, \triangleleft, \alpha) \) satisfies
\[
d \leq d' \land d \triangleleft M \land d' \triangleleft M' \Rightarrow M \leq M'.
\]
With such a relation it should be possible to see that the selection of a least fixpoint by a FPO in the first coordinate will force a proof of the same fact for the third coordinate.

**Categorical Semantics of FIX**

The semantics of FIX is in a rather unsatisfactory state. The definition of a FIX hyperdoctrine is complex and one would prefer more of its properties to be deducible from others. Originally a semantics which mimics the domain theoretic model of FIX was pursued, modelling FIX propositions via a distinguished class of subobjects in a suitable category (c.f. the hyperdoctrine model with fibres composed of inclusive subsets of \( \omega \text{cpo's} \)). In order to set up a categorical logic correspondence one has to manufacture a FIX category together with a distinguished class of subobjects from the FIX logic (this is essentially the Grothendieck construction applied to the initial FIX hyperdoctrine). However, the category arising from such a construction is not cartesian closed; and it is not clear how to alter the FIX logical system in a consistent way to ensure cartesian closure. If this could be achieved one would hope that some of the conditions ensuring FIX soundness would come for free: consider the fibrewise induction conditions of a FIX hyperdoctrine (imposed) and the result which shows that Peano's axioms hold in a topos (toposes model predicates by subobjects).
The Existence and Disjunction Properties

The results about existence and disjunction in the FIX logic work only for closed terms. It is possible to envisage relativised versions of these theorems, for example one could investigate for which propositions $\Phi(x)$ a judgement

$$\Gamma, x: \alpha, \Phi(x) \vdash \Diamond(E(x), y, \Psi(x, y))$$

in the FIX logic entails that there is a term in context $\Gamma, x: \alpha \vdash M(x)$ for which $\Gamma, \alpha \vdash E(x) = \text{Val}(M(x))$ and $\Gamma, x: \alpha, \Phi(x) \vdash \Psi(x, M(x))$.

Computational Adequacy Results for PCF

The results of Chapter 6 concerning computationally adequate translations of PCF into the FIX logic were proved using a technique due to Plotkin [Plo85]. It would be nice to see such results proven by a gluing argument. A skeleton of ideas for such a proof might be as follows: Define an operational semantics on the terms of the FIX logic with judgements of the form $\Gamma \vdash E \rightarrow M: \alpha$ where $\Gamma \vdash E: T\alpha$. This would be defined inductively by rules such as

$$\Gamma \vdash E \rightarrow M: \alpha \quad \Gamma, x: \alpha \vdash F(x): T\beta \quad \Gamma \vdash F(M) \rightarrow M': \beta$$

$$\Gamma \vdash \text{Let}(E, F) \rightarrow M': \beta$$

The operational semantics of FIX would be set up to ensure that $m \rightsquigarrow c$ iff $[m]^n \rightarrow [c]$; moreover if $\Gamma \vdash [m]^n \rightarrow V$, then $V \equiv [c']$ for some unique $c'$. The idea is then to use the equality $\Gamma \vdash [m]^n = [c]^n$ to deduce that $[m]^n \rightarrow [c']$ and hence $m \rightsquigarrow c'$, by way of a logical relations gluing argument. For example, recall the category $Lr$ of Chapter 5. If the definition of the relation $<$ of an object $(D, <, \alpha)$ had a clause of the form

$$e <_{\alpha} E \text{ iff } e = [d] \supset \exists M: \alpha. E \rightarrow M \quad (\ast)$$

we could use this (together with the formal adequacy of the FIX logic which shows that if $\Gamma \vdash [m]^n = [c]^n = \text{Val}([c])$ then the $\omega$co interpretation of $[m]^n$ is not bottom) to show that $[m]^n \rightarrow [c']$. The major obstacle here is that the terms $E$ and $M$ above are equivalence classes up to FIX logic equality. This problem could, perhaps, be surmounted by working at a 2-categorical level. Thus the initial FIX category $\mathcal{F}$ would be replaced by an initial "FIX 2-category". The latter would have types as objects, pure FIX terms as morphisms and 2-cells given by suitable reductions in the FIX logic, for example $\text{Let}((\text{Val}(M)), F) \rightarrow F(M)$. The notion of a FIX 2-category morphism would have to be formulated carefully, together with a proof that a category similar to $Lr$ but defined using the clause $(\ast)$ is indeed a FIX 2-category.

Semantics of PCF

The full abstraction problem for PCF has been investigated by a number of researchers [Plo77], [Sto88]. The FIX logic semantics given to PCF in Chapter 6 may
throw some light on the intricacies of full abstraction and possibly simplify known results; this is just speculation at the time of writing.

**Adequacy Results for Languages with Recursive Types**

We have not presented any applications of the $\text{FIX}_\infty$ logic. A first step would be to state and prove adequacy results for a PCF style programming language with recursive types. For example, if $x; \vdash \sigma$ were a type in context of the programming language, it would be translated to a judgement of the form $x; \text{dom} \vdash \nu \sigma : \text{dom}$. In particular, a recursive type $x; \vdash \mu x.\sigma$ would be translated as $x; \text{dom} \vdash \text{Fix}(x; \nu \sigma) : \text{dom}$.

**Synthetic Domain Theory**

Little is known about the exact links between the work of this thesis and similar ideas from synthetic domain theory. It is the case that complete $\Sigma$-spaces form a (constructive) model of the $\text{FIX}_\infty$ logic; for material relevant to synthetic domain theory see [Hyl82] and [Pho90]. One could perform a routine inter-translation of the systems to gain further incites into how they relate.

### 10.2 Final Conclusions

We have presented three logical systems which can be used to interpret programming languages. These logics can be used to give meaning to both call by name and call by value languages in a uniform way. Each logic has a clean categorical semantics together with a domain theoretic model. We have seen that one of these logics can be used to give computationally adequate interpretations of small programming languages. In essence, immediate future work consists of trying to simplify some of the categorical semantics, giving more extensive examples illustrating the use of the logical systems as program logics and in particular extending the applications to languages with recursive types.
