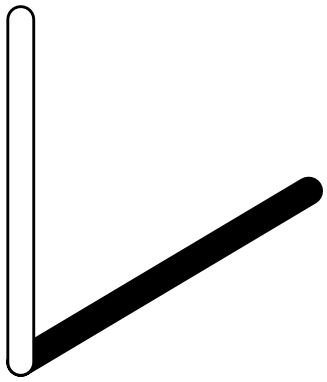
A Selection of Cambridge Sundials

There are scores of sundials in Cambridge and most of the really interesting ones can be admired without having to seek special permission from anyone. This handout gives a brief description of some of the dials that can be seen on a walk lasting one to two hours. The time taken depends on how long you spend looking at each dial!

1: Your own Personal Sundial



Keeping an eye on the length of your own shadow is a simple way of keeping track of time. The shadow is at its shortest at noon and steadily grows longer towards sunset.

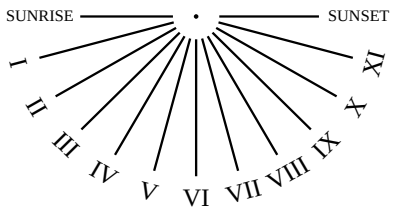
A vertical post set in horizontal ground allows for more accurate observation. One practical use is for the timing of the Muslim Dhuhur and Asr prayers.

Dhuhur prayers are said immediately after noon when the length of the shadow is just starting to grow. Asr prayers are said when the length of the shadow is its length at noon plus the height of the post.

2: Hypothetical Unequal-Hours Sundial

Most sundials have a *gnomon*, a rod or straight-edge which casts a shadow. The gnomon is usually polar oriented (so it is parallel to the Earth's axis). The direction of the shadow of such a gnomon at a given time of day is independent of the time of year.

Polar-oriented gnomons were unknown before the 14th century. Prior to that most sundials were intended to indicate *unequal hours* where the day is divided into 12 hours from sunrise to sunset. Such hours are short in winter and long in summer.



The standard design was very simple but inaccurate! A horizontal gnomon was mounted perpendicularly to a roughly south-facing vertical wall and then hour-lines were marked out at 15-degree intervals as shown in the figure.

The hours were numbered I to XII so that VI was midday, as in the expression 'at the sixth hour'.

The shadow of a horizontal gnomon at sunrise is horizontal (and to the west) and the shadow at sunset will also be horizontal (but to the east). This primitive sundial certainly shows the correct time at sunrise and sunset.

Moreover, if the wall is vertical and faces due south the shadow will be vertical at midday so this sundial will also show the correct time at midday.

Although arranging the in-between hour-lines at regular 15-degree intervals seems the obvious next step, this is not mathematically correct. Such sundials were very common but they divided the day somewhat irregularly, in time, from sunrise to sunset.

3: Downing College — Armillary Sphere

This is the only dial in the handout that requires special permission to visit. It is in the Downing College Rose Garden which is normally kept private for Fellows of the College and their guests.

An armillary sphere is a sphere made from a number of rings. The term comes from the Latin *armilla* meaning a ring or bracelet.

Like the majority of sundials this one is equipped with a polar-oriented gnomon, the straight rod which runs from one pole of the sphere to the other. This rod is parallel to the Earth's axis and, accordingly, lies in a vertical north–south plane. Its inclination to the horizontal matches the local latitude. The word gnomon comes from the Greek $\gamma\nu\acute{\omega}\mu\omega\nu$ meaning indicator.

Like a minority of sundials this one is also equipped with a *nodus*, the solid spherical ball mounted in the centre of the sphere on the gnomon.

It is only slightly naïve to imagine this instrument as a model of the universe itself. The nodus represents the Earth and the enveloping rings represent great circles drawn on the Celestial Sphere. The line of the gnomon runs from the North Celestial Pole to the South Celestial Pole.

The two most important rings are the horizon ring which is horizontal and the equatorial ring which is in a plane at right-angles to the gnomon. This ring is parallel to the Earth's equator and carries the time markings. This is the *dial* proper.

Time (strictly the local *hour-angle* of the sun) is determined by noting where the shadow of the gnomon falls among the time markings. At noon, an approximation to the date can be determined by noting where the shadow of the nodus falls on the ring that lies in a vertical north–south plane. The shadow is at its highest in late December.

4: Downing College — Horizontal Sundial

Horizontal sundials are so called because their dials are horizontal. These are the most common form of sundial and examples are found in numerous gardens.

The Downing horizontal sundial was made in 2000 for the bicentenary of the College by Quinten Hollick, a local sundial maker (notice the letter Q near the foot of the gnomon). This has a slate dial and a slate gnomon too. The various features on the dial (in this case all in gold leaf) are collectively known as *dial furniture*. The motto, *QUÆRERE VERUM*, is taken from the College's coat of arms and means Seek the Truth.

The two edges of the sloping face of the gnomon are known as *styles*. In the hours leading up to 12 noon the shadow of the west style is used and in the early afternoon hours the shadow of the east style is used. The reverse is true before 6 am and after 6 pm.

5: Downing Site — Polyhedral Dial

The Downing Site lies to the north of Downing College and is the home of many University Science Departments. The rather battered sundial near the Downing Street entrance to the site is actually a collection of 17 dials all cut into a single block of stone.

Each sundial has its own gnomon and a flat dial. The 34 styles of the 17 gnomons should all be parallel to the Earth's axis and therefore parallel to one another. Some are sadly bent!

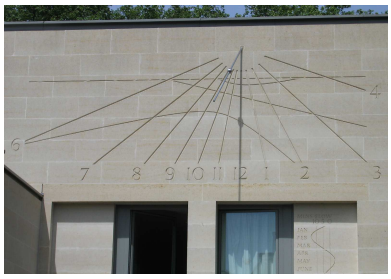
One consequence of having all gnomons parallel is that those which stem from roughly south-facing dials appear to point down into the ground and those that stem from roughly north-facing dials appear to point up into the sky. A few which are associated with dials that face due east or west have to be supported a short distance from their dials.

The 17 dials face in 17 different directions. At the top there is a horizontal dial (compare this with the Hollick dial in Downing College). Lower down there are eight vertical dials and in between there are eight sloping dials. These sloping dials are the most difficult to calculate and it must have been very challenging to determine the markings on the four triangular dials before the days of computers.

If you like long words you will enjoy the name of the shape into which the stone has been cut. This is an *elongated square gyrobicupola*, one of the Johnson solids. Sometimes the shape is called a *pseudo-rhombicuboctahedron*.

The sundial was presented by Professor Sir William Ridgeway (a famous archaeologist and classical scholar) and his wife Lucy in 1913. Their daughter, also named Lucy, married the son of John Venn (of diagrams fame). Sir William and (daughter) Lucy later set up the University's Ridgeway–Venn Travel Fund. According to University Ordinances, the first call on this Fund is for the maintenance of this sundial.

6: Pembroke College — Foundress Court Dial



The original proposal for this large wall sundial came from Eric Parry, the architect of the Foundress Court Building. The diallist was Frank King and the overall design was by Lida Cardozo Kindersley of the Cardozo Kindersley Workshop. Most of the stone cutting was undertaken by Helmut Hochrein. He cut the main dial in 1997 and the Equation of Time Panel in 1998.

The principal dial furniture consists of hour-lines marked from 6 am to 4 pm and three constant-declination curves (a pair of hyperbolic arcs for the two solstices and a straight line, called the equinoctial line, for the equinoxes).

This sundial has a gnomon and a nodus, both made of stainless steel. Time is determined by noting where the shadow of the gnomon falls among the hour-lines and the declination of the sun can be estimated by noting where the shadow of the nodus falls among the constant-declination curves.

7: Pembroke College — Memorial Dial

This horizontal sundial should be compared with that in Downing. It was originally made in 1957 as a memorial to a well-known orientalist, James Vere Stewart Wilkinson, but that dial suffered badly from weathering.

This replacement dial was made in 2005 and additionally commemorates Sidney Kenderdine, a noted astronomer. This dial is not wearing well either.

8: Little S. Mary's Church — Mass Dial

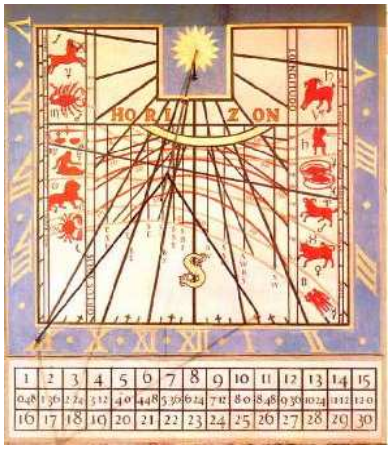
This dial is scratched onto a vertical surface of a roughly south-facing buttress of the church. It probably dates from the 14th century.

It was quite common in medieval times for churches to have rather crude sundials marked out so that the Priest knew when to call people to prayer, at certain *Canonical Hours*. These Hours included the times of the Christian Offices of Prime, Terce and Nones which were associated with the 3rd, 6th and 9th (unequal) hours.

This kind of sundial should be compared with the hypothetical unequal-hours sundial on page 1. The gnomon is missing but it would have been perpendicular to the dial..

Such sundials are known as Mass dials or, more descriptively, scratch dials.

9: Queens' College — The Queens' Dial



The Queens' Dial, painted on a wall in Old Court, is the best-known sundial in Cambridge. A dial was first set up here in 1642 and there have been many repaintings since that date. The appearance of the original dial is unknown. The present dial was painted in 1971.

Very few sundials have more dial furniture than this one! It incorporates more features than most users would ever have understood!

As on the Pembroke Dial, there is a gnomon and a nodus and, as usual, time is determined by noting where the shadow of the gnomon falls among the hour-lines.

The position of the shadow of the nodus indicates everything else. As at Pembroke there are constant-declination curves, though here there are six. Most of them are green but the equinoctial line is black.

It is common to have seven constant-declination curves, three pairs of hyperbolic arcs and a straight equinoctial line. Here the uppermost arc which would correspond to the winter solstice is obliterated by a golden arc which serves no serious dialling purpose.

The 12 Signs of the Zodiac have been painted in the spaces between the ends of the constant declination curves.

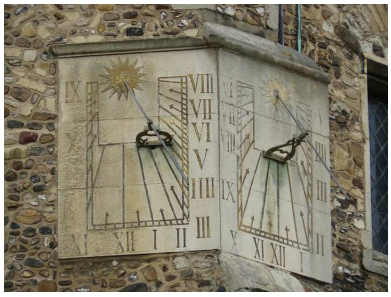
The family of red hyperbolic arcs indicates solar altitude; a low arc corresponds to a high altitude. The lowest such arc is labelled 60, for 60°. The highest arc in the family is the straight (black) line labelled HORIZON which, of course, corresponds to an altitude of 0°.

The family of thin black vertical lines indicates solar azimuth, the bearing of the sun. Notice the dominant gold S for South and the less obvious labelling such as SWBS for South-West By South.

There is another, fan-shaped, family of thin black lines which, via the shadow of the nodus, indicates unequal hours much more accurately than the sundial on page 1. At the latitude of Cambridge an unequal hour lasts a normal 60 minutes at the equinoxes but, in winter, it can be shorter than 40 minutes and, in summer, longer than 80 minutes.

There are numerous other features. One can tell the time of sunrise, the length of the day and, via the look-up table below the dial, the time by the moon. This is the only moon dial in Cambridge.

10: S. Botolph's Church — Dial Pair



This pair of vertical dials, on two faces of a buttress, can be seen on the south-west corner of S. Botolph's Church. These dials are the result of a restoration in 1913 and replace a much earlier dial whose appearance is unknown.

The dials are very clear to read and quite accurately laid out. When there are two dials, it can be embarrassing if they indicate different times!

11: Darwin College — Armillary Sphere

The armillary sphere in the grounds of Darwin College is less elaborate than that in Downing but it is in better condition.

There is no nodus and no horizon ring on this dial but the hour numbers on the inside of the equatorial ring are clearer than those on the Downing dial. The twelve Signs of the Zodiac are shown on the outside of the equatorial ring.

The equatorial ring is very wide and this can be a problem at the equinoxes when the side of the ring nearer to the sun shades the side further from the sun. The inside surface of the ring will thereby be in shadow all day. The sundial becomes temporarily unusable at these times of year.

In the Downing armillary sphere, this problem is reduced by making the higher side of equatorial ring thinner than the lower side. It is the lower side which has the hour numbers. In some designs, the higher side of the ring is cut out altogether.

12: Newnham Walk — Unequal-Hours Dial

This dial was finished in May 2010 and is a memorial to Margaret Stanier who was a Fellow of Newnham College and Editor of the *British Sundial Society Bulletin*. She was also a bellringer which explains the little bell that supports the gnomon.

The diallist was Frank King. The stone cutting and the overall design were by Annika Larsson who runs the noted Swedish design workshop *Inscriptorum*.

The sundial indicates a close approximation to unequal hours which is why the time at midday is VI rather than XII. To appreciate this dial you need to keep an eye on it at intervals over a whole year. In winter the shadow takes about 40 minutes to sweep from one hour-line to the next but in summer it takes about 80 minutes.

Margaret Stanier had a particular interest in Mass dials and the ends of the hour-lines of this dial lie in a circle as an echo of the normal arrangement on Mass dials.

13: Selwyn College — Sunrise/Sunset Dial

This dial was finished in March 2010. It was made in the Cardozo Kindersley Workshop who were also responsible for the overall design. The diallist was Frank King.

This sundial has a nodus but no gnomon and there are two families of hour-lines...

The time indicated by the golden hour-lines is the number of hours since sunrise. These are called Babylonian hours. The time indicated by the white hour-lines is the number of hours since sunset. These are called Italian hours. The average of these two times is the time indicated on a normal sundial with a polar-oriented gnomon.

The Greek motto ΚΑΙΡΟΝ ΓΝΩΘΙ at the heart of the sunburst means Know the Time or Recognise an Opportunity.

The Latin inscription *Collegio suo lactarius Eboracensis me dono dedit* is a reference to the benefactor: To his college the dairyman of Yorkshire gave me as a gift. The benefactor is Jim Dickinson, a Selwyn College alumnus.

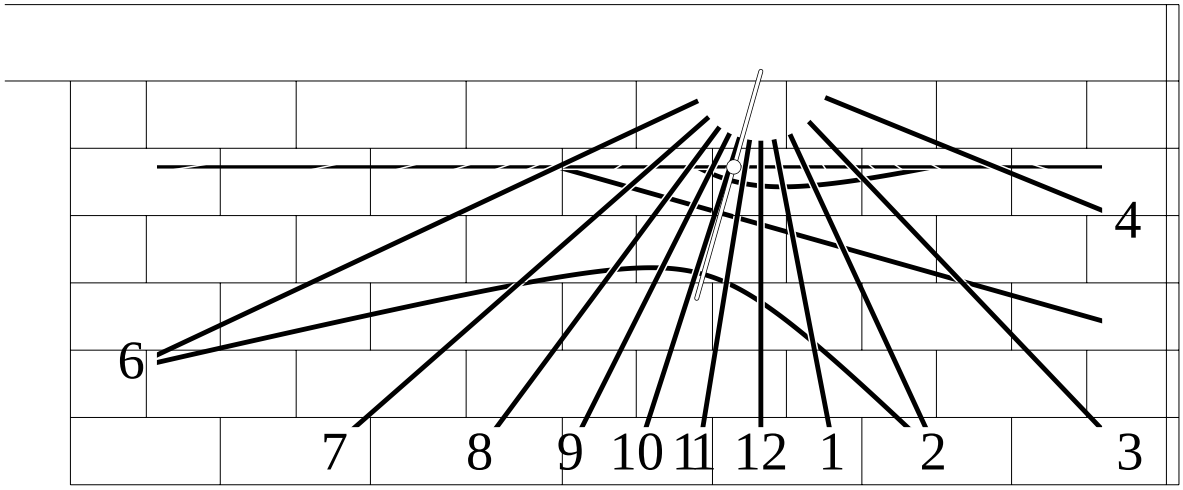
Acknowledgement

Much of the information in this handout has come from *Cambridge Sundials* by Alexis Brooks and Margaret Stanier, Pendragon Press, *ca.* 1990.

Frank King, Diallist 1 August 2010

Some Features of the Foundress Court Sundial at Pembroke

The figure shows the Pembroke sundial in elevation. The gnomon is about 1900mm long and the nodus, the stainless steel ball mounted on the gnomon, is 100mm in diameter.



All the markings on the dial are formed by deep V-cuts. Those for the hour-lines are 32mm wide. When the sun shines, the shadow of one edge of a V-cut falls into the depth of the cut and this shadow contrasts starkly with the bright limestone wall. In this way the sun brings the whole dial to life.

During the course of a day the shadow of the gnomon sweeps anti-clockwise across the dial and falls along the V-cuts of the hour-lines in turn. It is instructive to watch the shadow creeping up to an hour-line. It is quite hard to judge precisely when the shadow and an hour-line coincide.

The sundial indicates local sun time. A graphical rendering of the Equation of Time is cut into a stone panel below the right-hand end of the dial. Subtract the Equation of Time from local sun time to determine local mean time.

The shadow of the nodus also sweeps across the dial and this shadow is confined between the two hyperbolic arcs. At the winter solstice the shadow follows the upper arc, starting at the left-hand end where this arc intersects the horizon line, the straight line on the same horizontal level as the nodus. You can tell that sunrise is about 8.15 am and, at the right-hand end, you can tell that sunset is about 3.45 pm.

At each equinox the shadow of the nodus follows the diagonal equinoctial line. Sunrise is at 6 am and well before sunset the sun is on the wrong side of the wall so there is no shadow. At the summer solstice the shadow of the nodus follows the lower hyperbolic arc.

Notice that the horizon line is broken between the more widely separated hour-lines. Like the hour-lines, the breaks radiate from the root of the gnomon. They indicate half-hours, quarter-hours, and in a few cases eighth-hours.
